161. To better understand the correlation and potential impacts, comprehensive scientific studies and assessments are necessary. These studies would need to evaluate the specific local conditions, fish populations, and cultural contexts of the coastal communities in question.

162. Mitigation measures that are proposed within the EMPr, the specialist acoustic studies, socio-economic impact studies and heritage impact studies such as adjusting survey timing and locations, implementing exclusion zones, and using sound mitigation technologies. can help reduce the potential negative impacts of seismic surveys on marine life. However, when it comes to the cultural and heritage associations of fish and the broader marine environment, proposing the above mentioned mitigation measures which solely focus on reducing direct impacts on

fish populations, may fail to address the complex nuances and broader concerns.[175]

163. Small-scale or subsistence fishers in coastal communities often have deep cultural and heritage associations with fish and the marine environment. Their practices, traditions, and identity are intertwined with these resources. Simply mitigating the direct impact on fish populations may not adequately address the cultural and heritage significance of fishing. Preserving cultural practices, traditional knowledge, and the social fabric of coastal communities requires a more holistic approach that recognizes and respects their unique relationships with the marine environment.

164. Small-scale or subsistence fishers in coastal communities understand through their indigenous knowledge of fishing, that the marine ecosystem is capable of sensitivity to outside interferences. As fishers, they have observed that even the slightest interference with the sensitive marine ecosystem will have an impact on every fish in the ocean, and as a result their livelihoods. Plankton, for example, are the most sensitive to any interferences which indirectly have implications for the larger fish species that feed on plankton. Scientific experts have confirmed in their expert assessments that it is likely that the sound blasting in the ocean caused by seismic surveys will impact on the behaviour of plankton decreasing the number of plankton in the water.[176] Furthermore experts are of the opinion that seismic testing will have a significant adverse impact on numerous species of marine fauna, including endangered and vulnerable species located in the exploration area, and zooplankton.[177]

165. Mitigation measures that solely focus on addressing direct impacts on fish populations may not be appropriate for effectively addressing the indirect and cumulative effects on the broader ecosystem/ecocentric based cultural and

[175] Page 217-218 of the FBAR

[177] Fewtrell, J.L. and McCauley R.D., 2012. Impact of air gun noise on the behaviour of marine fish and squid. Marine Pollution Bulletin 64 (2012) 984–993; Harris JM, Olbers JM, and Wright K. 2022. "Report on Scientific basis for concerns of significant harm inflicted to marine wildlife by 2D and 3D Seismic Surveys on the South and West Coasts of South Africa."

JL28

heritage rights associated with fishing. Eco-centric based cultural and heritage rights are rights that can be defined as rights that acknowledge that ecosystems, species, and natural elements have their own rights and should be respected and preserved for their inherent worth, beyond their instrumental value to humans. Within this framework, cultural and heritage rights are understood in relation to the natural environment. Ensuring the protection of eco-centric based cultural and heritage rights involves recognizing and safeguarding the cultural practices, knowledge systems, traditions, and spiritual beliefs of indigenous and local small-scale or traditional fishing communities and other groups that have a close relationship with their surrounding ecosystems. These rights encompass the right to maintain and protect cultural landscapes, sacred sites, traditional ecological knowledge, and sustainable resource management practices.[178]

166. The examples of proposed mitigation measures formulated by the EMPr inadequately acknowledge the substantial impact on ecosystem/ecocentric based cultural and heritage rights resulting from the broader indirect and cumulative consequences on fishing populations.

166.1. Implementing exclusion zones to minimize direct impacts on fish populations and sensitive habitats does not sufficiently address the broader ecosystem/ecosystem based cultural and heritage associations of fishing. While exclusion zones can help protect specific areas from immediate harm, they may not consider the holistic connections between fish populations, migration routes, and the cultural practices of coastal communities that extend beyond specific locations.

166.2. Using sound mitigation technologies, such as acoustic deterrent devices, can help reduce the direct impacts of seismic surveys on marine life. However, these measures may not fully

[178] Akwasi-Achemfuour (2021) Balancing the interests of wildlife and humans resulting in sustainable ecotourism: the case of Boabeng-Fiema Monkeys' sanctuary, Ghana. FL28

address the indirect and cumulative effects on cultural and heritage rights. They primarily focus on reducing noise levels and immediate physical harm, but do not consider the potential disruption of fish behavior, altered migration patterns, or changes to the ecological dynamics that are crucial to the cultural and heritage aspects tied to fishing.

166.3. Temporal restrictions, such as conducting seismic surveys during specific seasons or avoiding critical reproductive periods, may help reduce direct impacts on fish populations. However, these restrictions may not fully address the indirect and cumulative effects on the cultural and heritage rights associated with fishing. Cultural practices and traditional knowledge often extend beyond specific seasons and reproductive periods, and the long-term sustainability of fishing traditions and associated rights may depend on the availability of fish populations throughout the year.

166.4. Implementing measures specifically focused on protecting certain fish species or habitats may not comprehensively address the broader cultural and heritage rights tied to fishing. While protecting specific species or habitats is important for biodiversity conservation, cultural and heritage associations with fishing often encompass a diverse range of species, ecosystems, and traditional practices that go beyond the conservation of individual components.

167. To effectively address the indirect and cumulative effects on ecosystem/ecocentric based cultural and heritage rights associated with fishing, mitigation measures should take a more holistic and inclusive approach that consider and incorporate the following aspects:

167.1. Incorporating the perspectives and insights of coastal communities into decision-making processes, ensuring their meaningful participation in the development and implementation of mitigation measures.

167.2. Recognizing and preserving cultural and heritage practices by considering the broader socio-cultural contexts,

FL03

intergenerational knowledge transfer, and the long-term sustainability of traditional fishing practices.

167.3. Integrating traditional ecological knowledge with scientific research to inform mitigation strategies and ensure that they address the interconnectedness of fish populations, ecosystems, and cultural and heritage rights.

168. While the mitigation measures may focus on reducing direct impacts, there can be indirect and cumulative effects that are not fully addressed. Seismic surveys, even with mitigation, can still cause disturbances, alter fish behavior, or disrupt migration patterns, which may have cascading affects on the broader ecosystem.

169. Given the ecosystem impacts, seismic testing will likely result in a trophic cascade affecting all levels of the food chain and therefore indirectly impacting on small-scale fishing communities. The Fisheries Specialist failed to assess the potential impact of the seismic surveys on zooplankton in and around the survey area, as well as the knock-on effects that zooplankton die-off would have on the fish species on which small-scale and subsistence fishers rely for their sustenance and livelihood.[179] These indirect knock on and cascading effects on the dynamic and interconnected ecosystem could potentially affect not only food security for local small-scale fishing communities, but could also impact on the ecosystem/ecocentric based cultural and heritage rights associated with fishing. Counter to the requirements of NEMA and the NEM:ICMA, the BAR and the competent authority's decision does not consider impacts from an ecosystem perspective, and as a consequence, the "downstream" impacts have not been adequately assessed and presented to the DG.

170. Additionally, the cumulative impacts of multiple surveys or other anthropogenic activities in the area need to be weighed together. These indirect and cumulative impacts can have implications for cultural and heritage associations, as they may disrupt traditional practices and the functioning balance of the marine ecosystem.

171. Given the absence of a socio-economic impact assessment which adopts an ecocentric and ecosystem approach to the assessment of impacts, and which

[179] Page 77 -82 of Fisheries Specialist Study

EDS

should have evaluated the cascading impacts on food webs, and how this will impact on the right to access of sufficient food as well as the associated connections of heritage and cultural rights to the practices of fishing, relevant information was not placed before the decision-maker. In the absence of that information, a precautionary approach should have been adopted. This omission is material – the right to food and culture and heritage are constitutionally enshrined – and consequently the authorisation should not have been granted.

172. Small-scale fishers often possess traditional ecological knowledge ("TEK"), which includes their understanding of fish behavior, spawning grounds, and the dynamics of the marine environment. This knowledge is often based on observations passed down through generations and is deeply connected to their cultural heritage. Proposing mitigation measures without considering and incorporating TEK may overlook valuable insights and alternative approaches that could better protect both the fish populations and the ecosystem/ecocentric based cultural and heritage rights of coastal fishing communities

173. Given the above, it is submitted that the proposed and authorised mitigation measures are inadequate. The mitigation measures set out in the EMPr are designed to re-assess impacts post-project.[180] This is flawed for a number of reasons, including:

173.1. The proposed measures are aimed at providing "resources and support for communities to develop and undertake safeguarding measures or plans to enhance the mitigation capacity of their intangible cultural heritage by fostering dialogue, mutual understanding and reconciliation between and within communities" which in no way holds TGS accountable for any impacts caused by the 3D seismic surveys activities.

173.2. The proposed mitigation measures fail to comprehend and mitigate any of the economic or other harms to livelihoods, and cultural and heritage practices and identity.

[180] Page 30 of the EMPr

174. The pre-mitigation significance given to the socio economic and cultural and heritage impacts are rated as Medium, and then Low post mitigation. If mitigation does not actually change the impacts, then it is implausible that the rating can change significantly as well. There is no rational connection between the results of the arbitrary, and somewhat absurd, mitigation measures and any change in significance with regards to the impacts caused by the reconnaissance activities on coastal communities.

175. The Social Impact Assessment (SIA) and Heritage Impact Assessment urges the need for dialogue and engagement with communities prior to the commencement of these activities as the Expert confirms that the oil and gas companies do not have a social license to continue currently.[181] However, there is evidence of any further dialogue with these communities with regards to addressing issues specifically relating to the indirect and cumulative effects on cultural and heritage rights associated with fishing.

176. Therefore, engaging and involving coastal communities in the decision-making process is crucial. Meaningful consultation and participation allow communities to express their concerns, share their knowledge, and contribute to the development of effective mitigation measures. Failure to include the perspectives and needs of these communities can result in measures that do not adequately address their cultural and heritage associations and may lead to further marginalization.

177. Despite the apparent expert knowledge and the level of understanding expressed in the report recommendations regarding the potential effects of the seismic survey proceeding on the communities' identity, sense of place, and spiritual, cultural, and indigenous rights, and that decisions must consider the interests, needs, and values (our emphasis) of all interested and affected parties, including acknowledging all forms of knowledge, including traditional and ordinary knowledge,[182] it is clear that necessary deep conversations with coastal communities were not conducted. Consequently, insufficient information was

[181] Page 109-110 of the SIA, and page 56, 58 of HIA.
[182] Section 2(4)(g) of NEMA.

JL28

placed before the decision-maker, and he/she neglected to afford sufficient weight to the indigenous and cultural rights of coastal communities.

Ground 6: *Failure to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008*

178. Section 63(1) of NEM:ICMA requires a competent authority to take account of specific factors when deciding whether or not to grant an environmental authorisation under NEMA for "coastal activities". By virtue of this section, the decision maker ought to have appreciated that in deciding whether to grant an environmental authorisation or not, he or she was required to consider additional factors specified in section 63 of NEM:ICMA[183] and whether or not the proposed project "would be contrary to the interests of the whole community". This required an eco-centric consideration of the impacts of the proposed project in an area that must be afforded a particularly high standard of protection given the natural functioning of the dynamic coastal processes.

179. Section 12 and 21 set out the State's obligation in relation to the management of the coastal zone, which must be taken into account in taking a decision in respect of this zone.

180. The Director-General's decision makes no mention of section 63 of NEM:ICMA, and the ESIA contains no evidence that the factors set out in section 63 was considered or assessed. Whilst the BARidentifies that section 63 of NEM:ICMA is applicable, it does not assess each of the factors set out in section 63.

181. Read together, this means that there was no factual investigation as required by section 63 of the NEM:ICMA, including a determination of whether the coastal public property and the coastal protection zone would be impacted, and if so, to what extent the proposed activity is consistent with the goal of establishing

[183] S 63(1)(c), s 63(1)(h)(i), s 63(1)(h)(iv) and s 63(1)(l) of NEM:ICMA.

BLS

or protecting those areas.[184]The management plans that are relevant in these areas, like the Coastal Management Programme for the Western Cape Province,[185]have also not been taken into consideration.

182. The BARdoes not, at any point, consider the interests of the affected human and non-human communities in any collective way. Consequently, the interests of the whole community[186] have not been presented to the decision-maker in the BAR, and without evidence of specific consideration of these interests in the Reasons for the Decision, the decision-maker has not evaluated these interests in their decision to grant environmental authorisation.

183. As set out elsewhere in this appeal, the impacts associated with seismic surveys could have significant impacts on marine life and coastal communities. Oceans play a critical role in regulating the climate and mitigating global warming by absorbing carbon dioxide. Seismic surveys pose a significant threat to functioning marine ecosystems, to living organisms in South Africa's coastal waters,and to communities that depend upon the oceans for their livelihoods. Small-scale fishers and fishing-dependent communities are particularly vulnerable to the negative impacts on fish stocks upon which they depend for their livelihoods.

184. The Appellants submit that it is not in the interests of the whole community (from and intra- and inter-generational perspective, as well as having regard to potential

---

[184] Section 63(1)(c) of NEM:ICMA.

[185] Western Cape Coastal Management Programme: 2016 available at https://cer.org.za/wp-content/uploads/2009/12/Western-Cape.pdf
Draft Western Cape Coastal management Programme 2022 – 2027 available at https://www.westerncape.gov.za/eadp/files/atoms/files/DRAFT%20Western%20Cape%20Provincial%20Coastal%20Management%20Programme%202022-2027.pdf.

[186] In terms of the National Environmental Management: Integrated Coastal Management Act 24 of 2008 (NEM:ICMA), the 'interests of the whole community' is defined as meaning the collective interests of the community determined by:

(a) prioritising the collective interests in coastal public property of all persons living in the Republic over the interests of a particular group or sector of society;

(b) adopting a long-term perspective that takes into account the interests of future generations in inheriting coastal public property and a coastal environment characterised by healthy and productive ecosystems and economic activities that are ecologically and socially sustainable; and

taking into account the interests of other living organisms that are dependent on the coastal environment.

impacts on living organisms in South Africa's coastal waters) to expose our oceans and coasts to the increased risks associated with seismic surveys, or associated with further intended exploratory drilling and/or production activities.

Ground 7 *Failure to provide adequate reasons for the decision*

185. The reasons for the DG's decision, as described in Appendix 1 of the Environmental Authorisation ("the EA"), sets out that the following were 'key findings' that resulted in the decision to approve TGS's application for environmental authorisation:

186. The decision concludes as follows:

> *In view of the above, and having taken into consideration environmental management principles as set out in section 2 of NEMA, this Department is satisfied that the proposed activity will not be in conflict with the objectives of Integrated Environmental Management set out in Chapter 5 of [NEMA] and will not result to any detrimental risks to the environment and public. The environmental authorisation is accordingly granted.*

187. These reasons, and the conclusion arising from these reasons are generic and unsubstantiated. The reasons are almost verbatim the same reasons provided by the DG in other oil and gas related applications, such as those contained in the Environmental Authorisations for Searcher Geodata UK Limited and TotalEnergies EP South Africa Block 567 (Pty) Ltd . The EA itself further fails to deal substantively with any of the main issues raised by the Appellants and other I&APs.

168. On the reasons provided, it is impossible to conclude that the DG took all relevant considerations into account, including the submissions made by the Appellants and other interested and affected parties.

169. To the contrary, it appears that the DG failed to consider all relevant information, for the reasons set out elsewhere in this appeal.

Ground 8. Decision to grant authorisation contravenes NEMA Principles, the Constitution and PAJA

190. Section 33 of the Constitution recognises that everyone has the right to administrative action that is lawful, reasonable and procedurally fair. PAJA seeks to give effect to this right.

191. From what is set out above, it is clear that the decision to grant authorisation to TGS runs contrary to at least the following NEMA principles:

> 191.1. Decision-makers must apply the precautionary principle when there is uncertainty or lack of scientific consensus regarding potential environmental harm. This principle requires taking preventive action to avoid serious or irreversible environmental damage, even in the absence of full scientific certainty.[187]
>
> 191.2. Decision-making should promote equity and fairness in the distribution of environmental benefits and burdens. This principle recognizes the rights of all individuals, particularly disadvantaged and vulnerable groups, to a healthy environment and seeks to avoid disproportionately negative impacts on these groups.[188]

[187] Section 2(4)(a)(vii).
[188] Section 2(2) and 2(4)(c).

FWS

191.3. Decision-makers must protect and conserve ecosystems, biodiversity, and ecological processes. This principle recognizes the intrinsic value of ecosystems and the critical role they play in supporting life and maintaining ecological balance.[189]

192. It is further submitted that

192.1. irrelevant considerations were taken into account or relevant considerations were not considered;

192.2. the action itself contravenes a law or is not authorised by an empowering provision;

192.3. the action itself is not rationally connected to the information before the administrator; and

192.4. the exercise of the power or the performance of the function authorised by the empowering provision, in pursuance of which administrative action was purportedly taken, is so unreasonable that no reasonable person could have so exercised the power or performed the function.

193. The decision is consequently reviewable under section 6(2) of PAJA.

CONCLUSION

194. The Appellants have sent out in this appeal a number of grounds on which the decision to grant environmental authorisation to TGS was fatally flawed. The decision to authorise the project is consequently unlawful, in that it failed to comply with, *inter alia*, the Constitution and NEMA.

[189] Section 2(4)(b); Section 2(4)(o) and Section 2(4)(r).

195. For all the reasons set out in this appeal, Natural Justice and the Green Connection submit that the appeal should succeed and that the environmental authorisation granted to TGSby the Director General should be refused.

196. We reserve the right to supplement the grounds for review and evidence in support of each argument.

GROUNDS OF APPEAL.	RESPONDING STATEMENT	COMMENT BY THE DEPARTMENT / DMR
1. Issues with the consultation process: the co-op believes the consultation process was not done correctly, we do not believe that the information that was presented is accurate. We know that the government is for oil and gas, but as a community and a small-scale fisher organization we are against it. We have seen this happen in other countries, and it has messed the whole sea life up. That's why we see foreign boats in our waters. We say no but the government says yes. In a few years time we'll be like all the other countries with nothing in our waters and nothing for the generation behind us. We strongly say no to seismic surveys and oil and gas development.		
2. It is not an open and transparent participatory process according to MEMA. We go and listen to the consultations but do not consent to a seismic survey. TGS states that a mitigation measure is to "consult with communities on potential ways in which to		

1719

make a positive contribution to the communities." Why isn't this part of the consultation process? The private sector and the government should be coming to affected communities such as Port Nolloth with this question, instead of coming with only one option – either seismic surveys or exploration drilling. Why has nobody asked what the Port Nolloth community wants for development? Why would we agree to something that has absolutely no benefit for us? Meaningful consultation should allow us to decide what we want, not being told something that has the potential to destroy our livelihood and that is so significant to our culture.		
3. TGS states there is a "perceived impact" of the oil/gas industry on the fishing industry, not the actual impact on catch rates. We do not believe this to be true, as there have been studies and evidence of the harms of seismic surveys and issues with oil and gas developments, e.g., blowouts, that impact fish for years to come. For example, after the Deepwater Horizon blowout in 2010 in the Gulf of Mexico, fish and dolphins are still testing positive for the chemicals found in the oil that spilled. There		

1720

are scientific reports that were not included in the EIA that show different impacts on species from the noise of air guns used in seismic surveys. The difference in scientific information that is presented in the consultations and EIAs is concerning. Further, we are concerned about who is going to monitor the impacts of the seismic survey, and how will fishers and other coastal livelihoods be compensated if there is harm to marine life as a result of the survey.		
4. Does not meet South Africa's climate change goals, e.g., Paris Agreement and Kyoto Protocol, and effort to achieve net zero. The push for oil and gas does not align with South Africa's climate change goals, where the country is a signatory to meeting these challenges and reducing its carbon footprint. We believe that this seismic survey violates these agreements and our Constitutional right to Section 24 on the Environment. It violates our right to health and well-being as it affects our livelihood and food security. This survey has a direct impact on pollution and ecological degredation, does not promote conservation, and is not promoting justifiable economic and social development. There are no economic benefits of oil and		

1721

5029

gas to the Port Nolloth community.		
5. The government is allowing permits for activities that harm the ocean yet are diminishing quotas. We as small-scale fishers do not harm the ocean, yet are severely impacted by seismic survey activities. As TGS states, our livelihoods are "already compromised due to the fishing quota system, over-fishing, lack of employment opportunities, pollution, effects of climate change and the revent Covid pandemic." The government is not alleviating any of these challenges by allowing a seismic survey and oil and gas development. Even though this seismic survey is not in the exact boundary of our fishing grounds, we are still concerned that it will affect the migration patterns of the fish. Climate change and overfishing is already impacting those patterns and the amount of fish in the ocean, so please we do not want another activity that will harm the fish we depend on for our livelihood.

Scientific Evaluation of the Transkei and Algoa Exploration Areas: Environmental Management Programme (EMPr) Final Report 2013

Aaron N. Rice, Ph.D.

Executive Summary

In my expert opinion, based on best available science, the proposed surveys have a high likelihood of both acute and chronic impacts to marine life in the proposed region surrounding the Transkei and Algoa survey areas. The Environmental Monitoring Programme (EMPr) Final Report underestimates the spatial extent and ecological impacts from seismic airgun surveys. The repeated assertion in the EMPr of negligible impact to fishes, marine invertebrates and marine mammals, is in contrast to a broad body of peer-reviewed scientific literature, though much of it has been published after the EMPr was initially drafted. For example, some species, such as scallops and zooplankton, may experience serious injury and mortality even from a single pass of a seismic vessel; others, such as pilchard and demersal fishes, are likely to experience, on large scales, sublethal harm that compromises breeding, foraging, and other biologically essential activity. At least some populations are likely to experience these effects at a population level, through mortality, injury, and large-scale adverse behavioral response. The proposed buffer zones described in the EMPr are likely not sufficient to prevent or limit adverse noise exposure to marine animals. Given the important role that many marine mammals, fishes and invertebrate species occupy in the food chain, these effects could cascade to affect other marine species. I believe that extensive seismic surveys could have profound negative consequences for the region's ocean health and marine resources.

Reviewer Expertise

1. I am a research scientist in the K. Lisa Yang Center for Conservation Bioacoustics (formerly the Bioacoustics Research Program) at Cornell University. The Center is one of the world's preeminent research institutions in the field of marine and terrestrial bioacoustics, the study of sound in the natural world. Since 2017, I have also served as a faculty fellow at Cornell's Atkinson Center for a Sustainable Future, which supports multidisciplinary research and collaboration on topics related to environmental sustainability. I am also a graduate field faculty member in the Graduate Field of Natural Resources and the Environment at Cornell, and a courtesy faculty member in the Environmental Sciences Graduate Program at Oregon State University.

2. I hold a B.S. in biology from Davidson College (2000), an M.A. in marine biology from Boston University (2002), and an M.S. and Ph D in Organismal Biology and Anatomy from the University of Chicago (2004, 2006). I completed my postdoctoral training in the Department of Neurobiology and Behavior (2007-2009) and the Bioacoustics Research Program (2009) at Cornell University.

3. In my capacity as a university scientist and a member of the bioacoustics research community, I have collaborated on research projects and/or provided input to various federal agencies with an interest in marine bioacoustics, including the National Oceanic and Atmospheric Administration, Bureau of Ocean Energy Management, U.S. Army Corps of Engineers, U.S. Navy, Marine Mammal Commission, and National Park Service; agencies for the states of Maryland, Maine, Virginia, and New York, industry groups; and conservation organizations. I have served as a grant review panelist for the U.S National Academy of Sciences, the U.S. National Science Foundation, the Gulf of Mexico Research Initiative (through

ANR

SWB

the Council for Ocean Leadership), and the North Pacific Research Board. I am an editor for the peer-reviewed journal, *Endangered Species Research*. In 2014, I received the Partners in Conservation Award from the Department of the Interior for my work on the acoustic ecology of fishes and whales along the Atlantic coast.

4. My career is centered on marine bioacoustics. I study sounds made by aquatic species, including fishes and aquatic mammals, to understand the dynamics of wildlife populations, the function of marine ecosystems, and the effect of human influences on the environment. I have served as author or co-author of 61 peer-reviewed journal articles, 20 technical reports for government agencies or industry, 7 scientific book chapters, and given numerous (>80) presentations at national and international scientific conferences. Much of my research has focused on the organisms and ecology of the western North Atlantic Ocean and Gulf of Mexico, but this work has global application and relevance.

5. I have experience in bioacoustics across a wide range of vertebrate species, including research and publications on sharks, fishes, frogs, rodents, whales and birds. I regularly lecture on vertebrate sensory physiology, bioacoustics, underwater acoustic communication, and conservation bioacoustics at the university undergraduate and graduate levels. I am familiar with the function of sensory systems across different vertebrate species, including the ways in which species produce, perceive, and use sound

6. In preparing this declaration, I reviewed the 2013 Environmental Management Programme (EMPr) Final Report for the Transkei and Algoa Exploration Areas and the 2020 Transkei Algoa Exploration Right Environmental Compliance Audit (2020 Compliance Audit) for the proposed seismic surveys off the southeastern South Africa coast. I also reviewed the 1998 South Africa Marine Living Resources Act, and relevant peer-reviewed scientific

ANR

JLCB

publications focusing on bioacoustics and the impacts of ocean noise on marine wildlife. A full list of the scholarly articles cited in this declaration appears in a literature cited at the end of this document.

7. The purpose of this declaration is to explain the importance of sound for marine wildlife, describe the effects that seismic airgun surveys have on marine mammals, fishes and invertebrate species, and assess the risks and possible biological impacts. For the reasons stated below, I believe that the surveys described in the EMPr (as well as in the review of the mitigation measures in the 2020 Compliance Audit) do not fully capture the risk posed to marine wildlife and ecosystems, and if approved, could have severe and wide-ranging negative impacts

Importance of Sound for Marine Wildlife

8 Sound is a critical component of the life history of many, if not most, marine organisms (Au and Hastings 2008, Montgomery and Radford 2017). The ability to make and hear sounds is fundamental to their behavior, including for courtship, reproduction, feeding, navigation, avoiding predators, marking territory, and maintaining their social groups. Many species of fishes likely produce sounds for communication (Lindseth and Lobel 2018, Rice et al. 2022), along with nearly all marine mammals that have been examined (Au and Lammers 2007), and it is recognized as being increasingly important for marine invertebrates (Buscaino et al. 2011, Staaterman 2016). This profound reliance on sound by marine animals is due to the basic physics of the aquatic environment. Because water is a dense medium, sound travels faster and farther in the ocean than it does in air.

9 In the ocean, sound can propagate at distances of up to thousands of kilometers. Noise from ships has been recorded at the bottom of the deepest areas in the ocean (6-7 km deep)

AMR

BGB

(Dziak et al. 2017). By comparison, light from the sun (including light that is visible to humans, and ultraviolet light) only travels through the top 100-500 meters of the ocean (Losey et al. 1999).

10. Underwater, there are two physical components of sound: pressure and particle motion (Kuperman and Roux 2007, Au and Hastings 2008, Montgomery and Radford 2017). The pressure component of sound is generated through the compression and expansion of a standing wave as it propagates through a medium (in this case water). Particle motion is generated through the movement and acceleration of water molecules by the passive pressure wave. Until recently, the majority of underwater acoustics focused on the measurement of pressure and largely ignored particle motion (Popper and Hawkins 2018). Only within the last 10-15 years has particle motion been recognized as a salient acoustic cue for fishes and invertebrates (Horodysky et al. 2008, Wysocki et al. 2009, Radford et al. 2012, Zeddies et al. 2012, Popper and Hawkins 2018).

11. Hearing is an important sensory modality for most, if not all, marine vertebrates and many marine invertebrates (Hall 1967, Popper and Ketten 2008, Fay 2009). All vertebrates share a common evolutionary ancestry in the structure and function of their inner ears, and use the same anatomical and physiological mechanisms for receiving environmental sounds However, tetrapods (amphibians, reptiles, birds, and mammals) primarily detect the pressure component of sound, fishes are primarily responsive to the particle motion component of sound (Popper and Hawkins 2018, Duarte et al. 2021). While many invertebrates do not have the same ear or auditory structures that vertebrates possess, they do exhibit sensitivity to sound, particularly particle motion (Popper and Hawkins 2018), although the anatomical mechanism is

AWR

5/23

not identified in all cases (Buscaino et al. 2011; Hawkins et al. 2015; Hawkins and Popper 2016; Mooney et al. 2010; Popper and Hawkins 2018; Vermeij et al. 2010)

12. Sound is a fundamental component of marine habitats. Different ocean environments have distinct acoustic signatures that comprise their "acoustic habitat" (Merchant et al. 2015; Radford et al. 2010, 2014; Staaterman et al. 2013). These acoustic habitats are created from the combination of biological sounds (e.g., fish chorusing, snapping shrimp, urchin movement, whale calling) and environmental sounds (e.g., waves crashing, earthquakes, rain) (Hildebrand 2009, Pijanowski et al. 2011); anthropogenic sound is also a pervasive component of most marine soundscapes (Duarte et al. 2021). The addition of anthropogenic sounds to this soundscape disrupts the ability of animals to use naturally occurring acoustic cues and has detrimental effects on individual organisms, populations, and communities (Popper et al. 2003, Nowacek et al. 2007, Weilgart 2007, Popper 2009, Popper and Hastings 2009, Radford et al. 2014, Shannon et al. 2016, Popper and Hawkins 2019, Popper et al. 2020).

13. Sound has many characteristics relevant to wildlife. Two of the most important characteristics are amplitude, or "loudness," which is typically measured in decibels (dB); and frequency, or "pitch," which is measured in Hertz (Hz). Marine organisms vary in their sensitivities to sounds of different amplitudes and frequencies. Fishes and invertebrates appear most sensitive to sounds in the lower frequencies (below 1000 Hz), which coincides with the principal frequency range of many anthropogenic noise sources, including seismic airguns. Marine mammals, by comparison, are sensitive across a wide range of frequencies.

14. Decibels represent the "loudness" or the intensity of sound as a logarithmic ratio of pressure (Au and Hastings 2008), analogous to the Richter scale for measuring earthquakes. As such, a 6 dB increase in sound level represents a doubling of the pressure, and a 20 dB

ANR

8203

increase represents a ten-fold increase in the pressure. Consequently, seemingly small increases in decibel levels represent large-magnitude changes in the sound that marine organisms are exposed to. Fish ears and brains are particularly sensitive to the "rise and fall" in the amplitude of a signal (Bodnar and Bass 1997, Bodnar and Bass 2001)

Noise from Seismic Airgun Surveys

15. Seismic airguns are used in geophysical exploration. They produce a series of high-amplitude underwater sounds, and the reflection of these powerful sounds off subterranean structures deep beneath the sea floor is analyzed to identify petroleum resources (Dragoset 1990, Caldwell and Dragoset 2000, Dragoset 2000). Airguns are often used in an array, typically consisting of dozens of guns that fire simultaneously, with a combination of gun sizes with volumes between 30-800 cubic inches, spread across about 200-1000 meters in area towed behind a ship (Caldwell and Dragoset 2000), to produce a better signal for detecting oil and gas resources (Dragoset 2000). A large airgun array can produce sound with effective peak amplitudes above 250 dB.

16. The sound produced by airgun arrays has a number of characteristics that heighten its potential to harm marine mammals, fishes and invertebrates. These include its frequency output and amplitude. Additionally, the potential impacts of airgun surveys are often evaluated on the basis of the sound characteristics from a single seismic airgun shot. However, industry-scale airgun surveys used for the exploration of oil and gas include dozens of airguns firing every 8-20 seconds during surveys last for months. Consequently, considerations of acute exposure from airguns to marine life fail to consider the cumulative and chronic exposure in full-scale seismic surveys.

ANR

5608

17. First, the sounds emanating from seismic airguns have frequencies that overlap with frequencies of greatest sensitivity for many marine mammals, fishes and invertebrates While airgun noise is described by acousticians as "broadband," meaning that it produces noise across a range of frequencies, with significant energy output at higher frequencies (Hermannsen 2015), most of the acoustic energy of the signal is concentrated between 100 and 1000 Hz. This is the range of primary sensitivity of fish hearing and energy content in fish communication sounds (Popper and Fay 2011, Popper et al. 2014, Popper and Hawkins 2019) Far less is known about marine invertebrate hearing, but experiments in squid (Mooney et al. 2010, Mooney et al. 2016) and crustaceans (Popper et al. 2001) suggest a similar frequency range (20-1000 Hz) for hearing for many of these species

18. Second, the high-intensity, low-frequency noise that airguns produce can typically travel long distances through seawater. My colleagues and I at Cornell have studied how airgun noise propagates through water in a number of ocean regions. In a 2016 study in the Gulf of Mexico, for example, we found that seismic surveys were detectable at distances greater than 500-700 km (Estabrook et al. 2016). Our colleagues at Scripps Institution of Oceanography have found similar results (Wiggins et al. 2016), and recent research from the Arctic has shown similar long-distance effects (Guan et al. 2015, Guerra et al. 2016, Keen et al. 2018). Other studies have detected seismic surveys at levels sufficient to mask, or obscure, baleen whale calls at distances of thousands of kilometers away from the source (Nieukirk et al. 2004, Nieukirk et al. 2012). Propagation distances are influenced by water depth, temperature, the composition of the sea bottom, and oceanographic conditions. In assessing impacts or establishing protective measures, regulatory agencies assume sound does not affect marine life beyond a few kilometers

AWR

5L02

from the source, in fact, airgun noise influences and degrades the acoustic habitat of marine species over a far greater area.

19. Third, the noise produced by airgun arrays becomes virtually continuous at greater distances from the source. This happens through a combination of multipath sound propagation and reverberation, where sound waves originating from the array reflect off the ocean surface and seafloor as they travel. In one of our studies off Greenland, we found that, across distances of 40 km, airgun noise elevated ambient sound levels by more than 25 dB (approximately a 4-fold increase in noise levels), and these sound levels remained elevated even during the periods between airgun blasts (Guerra et al. 2016). Similarly, in our observation of seismic surveys in the Gulf of Mexico under open ocean conditions, the noise produced by seismic arrays spread across the interval between seismic shots, and were sustained for months at a time (Estabrook et al. 2016, Wiggins et al. 2016).

20. These results demonstrate that sounds emanating from seismic airguns do not behave as individual and finite sound sources *in situ*, but lead to a continuous increase in the sound level through reverberation. The effect has repeatedly been documented (Nieukirk et al. 2004, Nieukirk et al. 2012, Guan et al. 2015, Estabrook et al. 2016, Guerra et al. 2016). At these distances, the noise was shown to spread between seismic shots with remarkably little loss of energy. While it is difficult to compare water-borne and air-borne noise, a reasonable analogy is that an industry-scale seismic survey presents the equivalent of organisms living through a continuous 4- to 6-month thunderstorm covering a distance greater than 40 km, a phenomenon that does not occur in nature.

AMR

5/23

Effects of Seismic Noise on Marine Wildlife

21. Marine mammals, fishes and invertebrates play a vital role in the ocean ecosystem. They are the ocean's predominant food sources both for apex predators, such as whales, sharks, and large fishes such as tuna and swordfish, and in support of human health and food security.

22. Marine invertebrates (ranging from phytoplankton to worms to crustaceans to jellyfish) are extremely diverse and numerous, and are categorized into 30 different phyla. They are the dominant group of organisms in all ocean ecosystems around the world and form the base of all ocean food chains. An increasing body of research shows that marine invertebrates are sensitive to sound (Budelmann 1992), and several recent studies reveal how marine invertebrates and their larvae exhibit adverse responses to increases in noise (Vermeij et al. 2010, Lillis et al. 2014, Lecchini et al. 2018).

23. Though marine invertebrates do not possess the same homologous ears as vertebrates, many invertebrates have anatomical structures, statocysts, that are sensitive to sounds through particle motion (Mooney et al 2010). Those invertebrates that have statocysts include species as diverse as decapod crustaceans, mollusks (including cephalopods and bivalves), cnidarians (including corals and jellyfish), and echinoderms (starfish, urchins, and sea cucumbers) (Budelmann 1992, Burighel et al. 2011). Among these taxa are a number of commercially important species such as lobster and scallop, as well as other very common marine species such as octopus. The statocysts contain a mineralized structure (the statolith) that is evolutionarily convergent with fish otoliths (a structure in the inner ears of vertebrates), function as an accelerometer, and are sensitive to the particle motion component of sound. And

AWR

FW28

similar to vertebrate ears, it is statocysts that are injured when exposed to high-amplitude sounds (Solé et al. 2013, Solé et al 2016, Solé et al. 2017).

24. Airguns have been shown to alter whale, fish and invertebrate behavior and habitat use in ways that are biologically significant. Exposure to high-amplitude (loud) sounds can cause acute effects, which are immediate, and chronic effects, which unfold over a longer time course. Some impacts are lethal to the organism, while others are sublethal. These diverse impacts include death, injury, changes in behavior, and changes in local abundance. This holds true across all studied classes of organisms in both marine and terrestrial ecosystems.

25. In critical respects, the assumptions made in the EMPr about risks and impacts of seismic surveys to marine mammals, fishes and do not reflect the current state of scientific knowledge. Since the drafting of the EMPr in 2013, a significant body of literature has been published describing the extent of seismic airgun surveys and the possible impacts to marine life (e.g., Zeddies et al. 2012, Nowacek et al. 2015, Hawkins and Popper 2016, Carroll et al. 2017, McCauley et al. 2017, Paxton et al. 2017, Bruce et al. 2018, Przeslawski et al. 2018, Elliott et al. 2019, Slabbekoorn et al. 2019), though some studies have produced conflicting or equivocal results to the larger body of work suggesting adverse impacts (e.g., Carroll et al. 2017, Cote et al. 2020, Sivle et al. 2021).

26. An increasing number of studies demonstrate physiological impacts to marine invertebrates from seismic airguns and other intense, predominantly low-frequency sound sources. These effects, which are consistent with theoretical predictions (Kight and Swaddle 2011, Francis and Barber 2013), include increases in physiological stress levels (Day et al. 2017), auditory injury (Solé et al. 2013, Solé et al. 2016, Sole et al. 2017), changes in behavior

ANR

JLCB

(Mooney et al. 2016, Day et al. 2017), and mortality (McCauley et al. 2017). The myriad impacts to invertebrates are remarkably similar to vertebrate responses to loud anthropogenic noises.

27. Marine invertebrate larvae are particularly vulnerable to adverse impacts from exposure to seismic airgun sounds. Such impacts have been shown to cause developmental abnormalities (de Soto et al. 2013), ultimately impacting survivorship of adults. Increases in anthropogenic noise levels can also disrupt the settlement of invertebrate larvae on coral reefs or oyster reefs, which is necessary for the larvae's survival (Vermeij et al. 2010, Lillis et al. 2014, Lecchini et al. 2018).

28. Seismic surveys also cause mortality and injury in plankton and mature invertebrates. In a controlled field experiment in Australia, blasts from a single airgun killed all krill larvae and more than half of the plankton within a 1-km radius from the airgun (McCauley et al. 2017). While this was a small-scale study, it has profound implications for ocean health, as it demonstrates that seismic airgun use may lead to major decreases in the foundation of the ocean's food webs, potentially resulting in a trophic cascade affecting all levels of the food chain. A recent study, following up on the McCauley et al. (2017) paper, produced conflicting results on the impacts of airgun surveys through controlled field experiments in Norway on copepods (Fields et al. 2019). This study did not demonstrate the same spatial extent of mortality in copepods that McCauley et al. (2017) found in other zooplankton taxa, and it is unclear if this is due to the fact that copepods respond differently to airgun sounds than other zooplankton species, or due to experimental differences. Although the conflicting results suggest the need for further study, they do not negate the findings of McCauley et al. (2017).

29. A subsequent study simulating the findings extrapolated from the results of the McCauley et al. (2017) study in the Northwest Shelf in Australia using a hypothetical seismic

ANP

5/08

airgun survey in water depths from 300-800 m (Richardson et al. 2017). In this simulation, a hypothetical zooplankton population is decreased by 32% from its initial level immediately following the seismic survey, and recovers to 95% of the original biomass in 18-41 days depending on the recovery rate. Additionally, the area of impact for plankton populations was within 15 km of the survey area. To summarize their conclusions in the beginning of the discussion section, the authors state: "We found there was substantial impact of seismic activity on zooplankton populations on a local scale within or close to the survey area, with a maximum decline of 22% in zooplankton populations in the survey area, 14% within 15 km of the survey area" (Richardson et al. 2017, pg. 26). Depending on whether oceanographic circulation was included in the simulation, plankton levels recovered within 3-57 days (Richardson et al. 2017)

30. Airgun sounds also adversely impact the survivorship, behavior, physiology, and haemolymph (analogous to vertebrate blood) biochemistry of scallops, and likely other bivalves. And, as noted above, the sound-receptive structures known as statocysts experience injury on exposure to airgun and other low-frequency sounds, indicating a mechanism of acoustic injury that exists across a range of invertebrate taxa: octopus (André et al. 2011), squid (Solé et al. 2013), cuttlefish (Solé et al. 2017), scallop (Day et al. 2017), rock lobster (Day et al. 2019), and jellyfish (Solé et al. 2016).

31. Sublethal impacts from noise exposure occur at all levels of biological organization in vertebrates and invertebrates (Kight and Swaddle 2011), including cellular and molecular processes, physiological systems, behavior, and ultimately, survivorship (Kight and Swaddle 2011, Francis and Barber 2013). Communities, ecosystems, and ecosystem services are also affected by noise (Francis et al. 2009, Francis et al. 2012). While more data are available

ANR

5028

about sublethal impacts from noise on terrestrial organisms (including humans), the same principles apply to marine species.

32. Sublethal impacts are often difficult to measure. Because these impacts unfold over long periods of time for both individual animals and on the population level, it is more difficult to attribute cause to effect. This is particularly true for marine species, given the challenges of monitoring them in the wild. However, sublethal impacts can have substantial consequences for the health and survival of fishes and invertebrates. These demonstrated sublethal effects include increased stress and changes in behavior, which may lead to decreased reproductive activity, decreased foraging (Magnhagen et al. 2017), decreases in predator avoidance (Simpson et al. 2015, Simpson et al. 2016), immunosuppression (Filiciotto et al. 2017, Vazzana et al. 2017), and ultimately reductions in survivorship (Simpson et al. 2016).

33. Assessing the immediate behavioral responses of fish to airgun firing is difficult, since fish frequently leave the immediate vicinity of an airgun soon after firing; thus, most studies are performed on artificially-confined fish (Pearson et al. 1992, Wardle et al. 2001). When airguns are fired between 0 to 100 meters of experimental fish cages, the fish often try to swim away from the direction of the airgun, or perform a characteristic startle response, indicative of distress (Pearson et al. 1992, Wardle et al. 2001).

34. Many studies have examined the effect of loud anthropogenic noise sources—including shipping noise and seismic airgun activity—on fish hearing and physical trauma to their ears (Popper et al. 2003). Fish exposed to broadband, high-intensity noise (about 153 dB) show decreased hearing sensitivity (Wysocki and Ladich 2005), and these effects often occur as late as 24 hours following exposure (Smith et al. 2004). Species with particularly sensitive hearing abilities may be more susceptible to auditory damage (Mann et al. 2007). A loss of

AMR

5103

hearing sensitivity is especially concerning when elevations in environmental noise may mask biologically important sounds (Myrberg 1990, Wysocki and Ladich 2005), such as the ability of fish to hear reproduction vocalizations, as shown for the Lusitanian toadfish (Vasconcelos et al. 2007). Anatomical studies examining the effect of airgun firing on fish ears demonstrate that substantial damage to the ears of at least some species is detectable up to 58 days following exposure, including blistering of the sensory epithelia and ablation of hair cells (either via "ripping" or "rupture") (McCauley et al. 2003). Fish exposed to five shots from airguns (a total of five seismic blasts) show a substantial and immediate decrease in hearing sensitivity (Popper et al. 2005). While the ultimate impact on fish survival is unclear, repeated or sustained airgun exposure is likely to have deleterious effects on fish health, not just limited to hearing (McCauley et al. 2003).

35. Another sublethal effect of airgun activity on fish is the physiological stress response. There are three different, well-characterized phases for the physiological responses of stress: 1) a primary stress response, characterized by an increase in stress hormones such as cortisol, which is considered to be a major "stress hormone," and catecholamines such as epinephrine; 2) a secondary stress response, characterized by a change in blood parameters (e.g., lactate); 3) and a tertiary stress response, characterized by decreased reproductive activity, immunosuppression, and ultimately, death (Santulli et al. 1999, Barton 2002, Wingfield and Sapolsky 2003). When exposed to loud (160 dB re 1µPa), broadband noise, some fish exhibit an increase in cortisol after 10 minutes (Smith et al. 2004). Another study demonstrated that some fish exhibit an increase in cortisol levels following exposure to boat engine noise (Wysocki et al. 2006).

KWQ

5L28

36. Following airgun firing, fish have been shown to exhibit characteristic primary and secondary stress responses, including changes in cortisol (immediate increase), glucose (increase), lactate (increase), ADP (increase), and ATP levels (decrease); these parameters returned to baseline values after 72 hours (Santulli et al 1999). While fish seem to recover after limited exposure to airgun activity, repeated or sustained airgun activity can lead to chronic stress, directly affecting reproduction and adult abundance (Santulli et al. 1999)

37. Studies of impacts of seismic surveys on fisheries indicate large-scale displacement of some species. In the area of seismic surveys, catch rates of different fish species decrease (Engås et al. 1996, Streever et al. 2016). Engås et al. observed average decreases in haddock and cod catches of 21% for longlines and 50% for trawling, within a roughly 3000 km^2 area around an airgun survey, and did not return to pre-survey levels during the five days of study that followed. Fish catch within the immediate survey area (104 km^2) declined by 45-70%. Arctic researchers observed sustained declines in fish catches in Alaskan waters during periods of seismic airgun activity (Streever et al. 2016). The question is whether these decreased catches were due to increased fish mortality or habitat abandonment; but either scenario would be concerning, as they could lead to longer-term declines if airgun surveys are sustained or if fish fail to return.

38. Similarly, a seismic survey caused a 78% decrease in fish abundance on an Atlantic coral reef at night, the period when reef wildlife was ordinarily most active, although the survey came no closer than about 8 km (Paxton et al. 2017). These studies suggest that seismic surveys occurring near locations of high fish abundance could lead to major disruptions in fish habitat use or abandonment of important habitats, and are consistent with the short-term behavioral responses observed in caged-fish studies.

AINR

EJ 28

39 Most soniferous fish species primarily communicate in the 100-1000 Hz frequency band, the same range of maximum acoustic energy in airgun sounds. Airgun usage introduces the likelihood of large-scale masking for fish in different behavioral contexts. Some fish use contact calls to maintain school cohesion (van Oosterom et al. 2016), and these sounds are susceptible to masking from low-frequency anthropogenic noise sources (Putland et al. 2018). Additionally, the long-duration, low-frequency choruses of fish, which are critical to reproductive success, overlap with the frequency range of airguns (Parsons et al. 2016, Rice et al. 2016, Rice et al. 2017). Sustained airgun surveys have the likelihood of disrupting these choruses, which are critical for these species' reproductive success

40. It is important to note that controlled scientific experiments investigating seismic survey impacts on fishes and invertebrates are typically conducted with a single airgun (Popper et al. 2005). For example, the studies on zooplankton impacts (McCauley et al. 2017; Fields et al. 2019) used either a single airgun or two airguns (respectively), with a volume that is substantially smaller than some of the individual airguns that will be deployed during the authorized surveys as part of large, multi-airgun arrays. Thus, much of the experimental science does not accurately reflect the larger scale at which airguns are commonly used during exploration and therefore tends to underestimate the injury and behavioral responses they induce in aquatic organisms.

Possible Adverse Effects on Marine Mammals, Fishes and Invertebrates along South Africa's Eastern Coast

41. If allowed to go forward, the authorized surveys will occur in waters off the eastern of South Africa. Includes migratory routes of marine mammals, extensive fisheries, and

AWR

FC28

habitat of high diversity and abundance of fish and invertebrate species. Such biologically important habitat includes widespread temperate reef habitats and a large amount of designated Essential Fish Habitat, supporting hundreds of different species.

42. For fish and invertebrate species, the adverse effects of the authorized surveys would not be transient, short duration, or limited in its range. The noise produced by multiple large-scale surveys would be temporally and spatially pervasive within the region, due to the nature of the large-array seismic source and the amount of authorized activity (see Estabrook et al. 2016; Wiggins et al. 2016). The surveys will expose large areas to noise that are of biological importance to fishes and invertebrates on the continental shelf, along the shelf break, and in waters further offshore for extensive portions of the year. While the survey area includes a seismic buffer zone 10 km from the coast and 2 km from nearby Marine Protected Areas, sounds from airgun surveys are likely to still saturate near-shore habitats with airgun noise, and both coastal and offshore species will experience the mortality, developmental impairment, impacts to vital function, and other harms described earlier in this declaration. The spatial extent of these proposed buffer regions are insufficient to protect these habitats from exposure from elevated sound levels due to airgun noise.

43. The mitigation measures described in the EMPr for seismic airgun surveys in the project area are unlikely to prevent serious impacts on marine life. With respect to marine mammals, fishes and invertebrates, these mitigation measures are too short in duration to account for longer-term consequences, do not fully capture the mechanisms of harm from seismic surveys, and underestimate the possible area of influence.

44. Additionally, the reliance of Marine Mammal Observers for visual detection of marine mammals are only useful for spotting marine mammals during daylight hours with good

ANR

Jan 28

visibility conditions, there is a large likelihood of missing cetaceans and turtles during bad weather.

45. The EMPr further describes the use of passive acoustic monitoring to detect marine mammals, but these efforts are not described in sufficient detail to evaluate whether they would be effective or not. For example, towed arrays are commonly used for passive acoustic monitoring, but these methods are primarily effective for detecting higher-frequency vocalizations or clicks from toothed whales (e.g., Cato et al. 2010, Thode et al 2010, von Benda-Beckmann et al. 2010), as the lower frequency vocalizations from baleen whales are masked by flow noise from the moving survey vessel.

46 In evaluating the spatial extent of the influence of airgun sounds, EMPr mentions that there is a fourth spatial area with possible influence, "the zone of masking" (pg 6-16) ". . exists but is difficult to quantify." There have been numerous studies measuring or modeling the spatial area of masking for marine mammals from anthropogenic noise (Clark et al. 2009, Hatch et al 2012, Erbe 2015, Erbe et al 2016, Cholewiak et al. 2018), and this is now a relatively straightforward approach (e.g., Erbe 2015) and should be done as part of the EMPr. The EMPr states that a "safety distance" for baleen and sperm whales is the area of a 180 dB_{rms} (re: 1 µPa) and 210 dB (re: 1 µPa) for other odontocetes, yet this is approximately a 3-8x higher level of sound exposure than would be permitted under U.S. National Marine Fisheries Service regulations (NMFS 2018).

47. The EMPr asserts that impact from airgun surveys is negligible and short term (pg 6-18), but this assessment was made before the McCauley et al. (2017) study.

48. Since the EMPr was drafted, there has been a considerable amount of survey data made available. The proposed survey area does not include any quantitative data on the

ANR

occurrence of marine mammals or sea turtles, nor does it include any predictive modeling of sound fields by seismic airgun surveys (Keen et al. 2018) or risk assessments related to the population level consequences of marine organisms from airgun surveys (Farmer et al. 2018. Slabbekoorn et al. 2019).

49. The 2020 Compliance Audit of the 2013 EMPr states that the original proposed measures "sufficiently provide for the avoidance, management and mitigation of key environmental impacts identified and no recommendation for the update of the EMPr is considered necessary." This audit recommends that sea turtles should be included in visual monitoring before airgun firing, however, the spatial distance to harm or harassment of turtles from seismic airguns likely exceeds the 500 m visual detection range of protected species observers, particularly during night time or poor visibility conditions (Popper et al 2014).

50. Additionally, the 2020 Compliance Audit presents no new ecological or environmental data on the seasonal or spatial occurrence of protected or sensitive species or any new sound modeling demonstrating a decreased likelihood of impact from elevated noise levels from the seismic survey.

51. The 2020 Compliance Audit indicates that at 46 of the EMPr mitigation measures are not currently applicable (NCA), since airgun surveys have not started, and the 2 topics deemed to be in compliance – EMPr approval by PASA and protocol for a close-out report– have nothing to do with any updated or improved environmental compliance measures, and offers no improvement on previously insufficient monitoring and mitigation measures.

IN THE HIGH COURT OF SOUTH AFRICA
(EASTERN CAPE DIVISION, GRAHAMSTOWN)

Case No: 3941/2021

In the matter between:

SUSTAINING THE WILD COAST AND OTHERS Applicants

and

MINISTER OF MINERAL RESOURCES AND ENERGY AND OTHERS Respondents

---

SUPPORTING AFFIDAVIT

I, the undersigned,

DOUGLAS NOWACEK

do hereby make oath and say:

1 I am an adult male and the Repass-Rodgers Chair of Marine Conservation Technology in the Nicholas School of the Environment and the Edmund T. Pratt School of Engineering, at Duke University in Durham, North Carolina, United States of America.

2 The contents of this affidavit are to the best of my knowledge true and correct. Unless I indicate otherwise, or the contrary appears from the context, they are within my personal knowledge and belief.

3 My CV is attached marked DN1. I confirm that it is accurate.

Background and Expertise

4 I have studied the behavioral and acoustic ecology of marine animals throughout my professional career, with particular expertise in the subject of anthropogenic noise. I have authored or co-authored more than 100 publications on marine animal ecology and acoustics, with about one quarter of those papers and reports specifically focused on ocean noise, from analyses of acoustic sources to impacts on marine animals to the mitigation of those impacts.

5 In January of 2019 I provided an expert declaration that was filed in a United States court and which provided the court with a summary of scientific evidence about the impacts of seismic airguns on marine life, and in particular on North Atlantic right whales ("Expert Declaration"). Because of the short timeframe and urgency of this matter, I attach and incorporate herein the Expert Declaration (attached marked DN2), and use this declaration to clarify the Expert Declaration's applicability to the proposed seismic survey at issue here and identify other applicable scientific evidence (attached marked DN3).

6 I continue in my role at Duke University as the Repass-Rodgers Chair of Marine Conservation Technology in the Nicholas School of the Environment and the Edmund T. Pratt School of Engineering, at Duke University. The Expert Declaration describes in more detail my experience and background. Expert Decl. ¶¶ 2- 4.

7 For this opinion, I have reviewed Shell Exploration and Production South Africa notification letter for the Transkei Survey, dated 29 October 2021. I have also reviewed sections of the 2013 Environment Management Programme (EMPr) describing the seismic survey and mitigation measures for cetaceans. I also have reviewed the chart of threatened and protected cetacean, bird and fish species present in the survey area included in the report by Simon Elwin and Tess Gridley, dated 2 December 2021.

8 It is my understanding that the EMPr for the project was completed in 2013. According to the EMPr, a vessel will tow an airgun array with up to 12 or more lines of hydrophones spaced 5 to 10 meters apart and between 3 and 25 meters below the water surface. The array can be upwards of 12,000 meters long and 1,200 meters wide. The airgun would be fired at approximately 10 to 20 second intervals, and would be expected to produce sound levels of around 220 decibels.

Expert Declaration's Conclusions May be Applied to Seismic Surveying Activities in South Africa

9 My Expert Declaration describes how seismic airgun noise travels in the ocean and discusses harms from seismic surveys to marine mammals, Expert Decl. ¶¶ 7- 15. I summarize some of the key points below.

10 Seismic airgun noise has a number of characteristics that give it a remarkably large acoustic footprint. The sounds that seismic arrays produce are among the loudest that humans regularly introduce into the ocean, exceeded only by the occasional

use of explosives. Seismic noise can also travel great distances and has been heard at distances of up to nearly 4000 kilometers (km). Seismic airgun noise also has a broad temporal scale. While airgun arrays are loudest when they are firing, they also significantly elevate background levels of noise between shots. The sound that results is said to "spread" across the interval between pulses, becoming virtually continuous at distance. Seismic airguns are, in effect, a hybrid source, producing both a powerful impulsive sound that can be damaging if the receiver is too close and a virtually continuous sound that raises ambient noise levels at much greater distances. Expert Decl. ¶¶ 37-38. Thus, marine animals exposed to noise from seismic airguns must contend with both loud individual pulses every 10 to 15 seconds and with continuous reverberating energy in the periods between the pulses.

11 In addition to describing these general harms, my Expert Declaration focuses in detail on the impacts to North Atlantic right whales from acoustic surveys, Expert Decl. ¶¶ 16 – 39, relying on, as well, studies on baleen and bowhead whales to draw informed opinions. Expert Decl. ¶ 18. North Atlantic right whales, *Eubalaena glacialis*, are the same genus as Southern right whales, *Eubalaena australis*, which are found in the Transkei seismic survey area between July and November. Because they are from the same genus, scientifically the studies and general conclusions (i.e. those that do not relate to activities or bathymetry specific to the Atlantic) may be interchangeably applied.

12 Studies on bowhead and other baleen can be relied upon to make informed opinions about other whales that are in the Shell survey area because baleen whales are all members of the sub-order *Mysticeti*, and share common features amongst themselves; this makes them appropriate proxies for assessing impacts on other baleen whales found in the seismic surveying area. According to the 2013 EMPr, the baleen whales in the seismic survey area include: Southern right whales (*Eubalaena australis*), Humpback whales (*Megaptera novaeangliae*), Minke (*Balaenoptera bonaerensis*), Dwarf minke (*Balaenoptera acutorostrata*), Fin whale (*Balaenoptera physalus*), Antarctic blue whale (*Balaenoptera musculus musculus*), Sei whale (*Balaenoptera borealis*), Bryde's (inshore) (*Balaenoptera brydei (edeni)*), and Pygmy right (*Caperea marginata*). While we have very limited data on many of the species in this list, the general conclusions about impacts (i.e. those that do not relate to activities or bathymetry specific to the Atlantic) may be applied to the baleen whales that will subject to seismic surveys taking place in the Transkei.

13 The following main findings from my Expert Declaration are applicable to the Transkei survey:

13.1 Noise from the seismic activity will likely adversely impact the cetaceans in at least three ways: 1) by inducing a physiological stress response; 2) by disrupting biologically essential behavior such as vocalizing, mating, or foraging; and 3) by masking acoustic communication, including communication between mothers and calves, Expert Decl. ¶¶ 19 – 39.

13.2 The noise from seismic surveys would be felt by cetaceans over large areas of ocean because sound travels farther and faster in water than in air and the acoustic energy from airguns can propagate hundreds to thousands of kilometers in marine environments. Expert Decl. ¶¶ 7– 15, 35 – 39.

13.3 The noise from seismic surveys experienced by sound-dependent marine animals, would not be limited to the pulse of the airgun shot and includes an increase in the median ambient noise in the ocean even at a distance of 100 kilometers. Expert Decl. ¶¶ 35 – 39.

13.4 Mitigation measures such as time-area closures, visual observers, and passive acoustic monitoring and "soft starts" or "ramp ups" are inadequate to protect cetaceans present year-round or deep-diving beaked whales. Expert Decl. ¶¶ 40 – 47.

Scientific Understanding of Acoustic Impacts on Marine Animals Has Evolved Since 2013

14 Like the ocean, science is dynamic. The field of acoustics in the marine environment has evolved substantially since 2013 when the EMPr was completed.

15 The EMPr, even prior to the consideration of the lowering effect of mitigation factors, found overall impacts to marine animals by seismic noise during the operational phase of activities that ranged from negligible (phytoplankton & zooplankton; invertebrates, including squid) to low (fish; turtles; seabirds, including penguins) to

medium (cetaceans). EMPr 6-11 to 6-42, and table 6.3 at 6-53 to 6-54. Recent scientific literature that was not considered in 2013 contradicts these findings.

16 A 2021 literature review provided a systematic assessment of 536 scientific papers relating to the "effects of impacts of anthrophony and other human alterations to ocean soundscapes on marine animals" (Duarte et al., 2021). The review examined published literature since 1970 and demonstrated that there was a significant post-2010 uptick in published papers on the subject (Duarte et al., 2021). That same review demonstrated that 74.4% of those studies statistically testing the impacts of seismic surveys on marine animals found significant negative impacts to these animals from the surveys (medium-high confidence) (Duarte et al., 2021). For another example, a 2017 study found that a single airgun blast kills over 50% of zooplankton within a 1 kilometer radius, contradicting the 2013 EMPr's assertion that the seismic surveys will have negligible impacts on phytoplankton and zooplankton (McCauley et al., 2017). As an intermediary between primary producers (plankton) and fish, marine mammals, and birds, zooplankton are vital to ocean productivity and healthy ocean ecosystems. Similarly, while the EMPr found a medium impact on cetaceans, scientists have found that even slight disturbances which result in the displacement of acoustically sensitive beaked whales may have population level effects, certainly an impact beyond medium significance. (New, 2013).

17 Lastly, important studies have taken place prior to and since 2013 that demonstrate the harms of seismic testing and anthropogenic noise on cetaceans. Post-2013

studies include examples of negative effects on cetaceans generally (Dunlap et al. 2021; Gomez et al., 2016; Castellote and Lorens, 2016; Nowacek et al. 2015) and specifically on physiological stress effects (Expert Decl. ¶¶ 20 – 23; Lemos et al., 2021 – gray whales); behavioral disruptions (Expert Decl. ¶¶ 24-31; Dunlop, 2015, 2020 – humpback whales; Bröker et al., 2015 - gray whales; Miller et al., 2015 & DeRuiter et al., 2013 – beaked whales, Pirotta et al., 2014 - porpoises), and communication disruptions (Expert Decl. ¶¶ 32-34; Tennessen and Parks 2016 - North Atlantic right whales; Cerchio et al., 2014 – humpbacks; Blackwell et al., 2013, 2015 – bowhead whales).

18 Since 2013, we have also come to understand much better how seismic gun noise is not limited to the airgun pulses themselves, but also increases ambient noise. Expert Decl. ¶¶ 35-39.

19 Lastly, presence and abundance can change in an eight-year period. Climate change for example is increasingly causing shifts in the timing and duration of migrations, changes in distribution, habitat lose, and reduced fecundity (van Weelden et al. 2021). Notably, at the time of the EMPr in 2013, humpback whales were presumed to be seasonal in the surveying area. See Table 6.4 of EMPr at 6-54. Without accurate data on which species are in the seismic survey area, how many, and when, there is a significant risk that mitigation measures could be rendered ineffectual.

FC2

Modeling

20 It is standard practice in the United States to model the acoustic footprint of the proposed survey over appropriate time and space scales. The effects could extend over hundreds of square kilometers. The EMPr contains no such modelling.

21 In addition, such modeling must analyze the aggregate sound field, not just the specific airgun survey, to estimate the overall influences of changes in the acoustic environment at appropriate ecological scales, the potential impacts on marine life, and the potential effects on populations (Southall et al., 2013). Given our rapidly improving understanding of the spatial, temporal, and spectral scales of the acoustic footprints generated by these seismic activities, the single-source regulatory approach is no longer appropriate (Southall et al., 2021; Nowacek et al., 2015).

22 Without acoustic modeling, the EMPr could not have accurately assessed the harms that the seismic survey could cause.

Mitigation Measures

23 An assessment for the harms of a seismic surveying activity that does not use the most current science and does not contain acoustic modeling cannot accurately assess the harms that this seismic surveying will cause. This means that mitigation measures could be inutile and misdirected. The mitigation measures proposed for seismic surveying in the Transkei include measures such as using visual observers,

passive acoustic monitoring, and the use of a "ramp-up" or a "soft start." These may be ineffective. The essential point is that, without any modelling, it is simply not possible to conclude that mitigation measures are effective at either reducing or eliminating harm.

24 In discussing the residual impact on cetaceans after mitigation measures, the EMPr characterizes the duration of the surveying activities of four-five months as "short." EMPr at 6-42. Four to five months of continuous seismic in an area of 6,011 km^2 is not short, particularly in the context of seasonal use of the area by a sensitive marine mammal. This is especially true when the data relied upon are at least eight years old.

Conclusion

25 In my opinion, the Transkei seismic survey which lasts four to five months will likely cause harm to marine mammals. The EMPr assessment did not use acoustic modeling and relied upon what is now eight-year old science regarding acoustic impacts on marine species and outdated information on the presence and abundance of animals in the seismic surveying area. Therefore, the proposed mitigation measures are of unknown efficacy, because the acoustic footprint of the survey remains unknown.

REPORT ON SCIENTIFIC BASIS FOR CONCERNS OF SIGNIFICANT HARM INFLICTED TO MARINE WILDLIFE BY 2D and 3D SEISMIC SURVEYS ON THE SOUTH AND WEST COASTS OF SOUTH AFRICA

Harris JM, Olbers JM, Wright K

14 January 2022

This report provides a summary of key findings in peer-reviewed literature on the physiological and ecological impacts of seismic survey activities on marine wildlife, with specific attention to the relevance of the information to the context of the Reconnaissance Permit Area (~297 099 km²) applied for by Searcher Geodata UK Limited, located offshore between the South African/Namibian border and Cape Agulhas, as well as with regards to vulnerable and endangered species known to occur in this area, with consideration of the proposed timing of the seismic survey operations being during the austral summer months. Having carefully considered the available information it is our opinion that seismic surveys do cause harm to both species and ecosystems, and that significant direct harm to individual animals and harm to populations of endangered species is the most likely scenario in the case of the seismic surveys off the south and west coasts of South Africa. Of specific concern is the impact on humpback whales and southern right whales which are still frequenting the west coast during the summer months (December – February), the impact on critically endangered (leatherback) turtles (migration routes in the area), the critically endangered African Penguin (changes in foraging behaviour and impacts on fitness) and the Cape fur seal (and consideration of current mass die-offs). We conclude that these seismic surveys are inadvisable in austral summer months due to the presence of these species in the area, the increasing anthropogenic pressures, and the inability of the prescribed mitigation measures preventing harm to individuals/populations. Furthermore, recent literature provides credible concern about ecosystem/food-chain impacts of seismic surveys, that may in turn have impact on fisheries, the severity and localisation of which will depend on coincidences with spawning and juvenile recruitment events. It is strongly recommended that further studies on

1 of 8

these impacts, in the South African context, are carried out *in situ* before proceeding with further seismic surveys of this nature.

Summary of Findings

- Based on peer-reviewed scientific literature, it is clear that physical damage to marine animals, including soft tissue trauma damage, embolisms, damage to organs used in balance and orientation, concussions, haemorrhaging, decompression sickness and both temporary and permanent threshold shifts to hearing ability have been directly linked to the kind and level of sound emitted during this nature of seismic surveys.
- There is plausible evidence to suggest that seismic survey activity is likely to affect the conservation status and recovery of populations of vulnerable and threatened species including (IUCN Red list species such as humpback and southern right whales), because sound and the ability to hear and interpret sound is critical for many species to reproduce (both vocalisations on breeding grounds and communications across large distances for mate detection). Therefore, it must be assumed that interference in sound perception or utilisation for communication (temporarily or permanently) has the potential to impact a species at the population level.
- Some species have been shown and documented to display physiological stress responses and behavioural changes to seismic activities, such as moving away rapidly, diving or remaining still. These responses are likely to increase their energy consumption and energy costs, reduce their time to forage, and/or affect their vulnerability to predation, thus having negative impacts on the survival of individuals (especially young or compromised animals) as well as the overall population growth and survival of a species (especially for threatened species that are already at risk of extinction).
- The impacts of seismic activities are most well studied for marine mammals, and evidence suggests that there are distinct avoidance responses such as leaving the area or ceasing to undertake everyday activities such as feeding in preferred areas. This is likely to negatively impact the "fitness" of an affected animal.

I.S.K

FIDS

- There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.
- The only existing field study in South Africa (that we have been able to find) on the impacts of seismic activities in our waters is illuminating in this regard. It presents clear evidence that the endangered, endemic African penguin avoided preferred feeding sites when a seismic survey was active nearby. This is particularly of concern for a species which has had a 70% decrease in numbers over the past decade, is stressed by prey depletion creating a greater demand for them to forage further afield, and for which the prospect of extinction is significant.
- The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.
- Recent research (2017) has shown significant mortality in zooplankton up to 1.2 km from a seismic survey array. Zooplankton forms the base of many important food webs in the marine environment. Depletion of zooplankton could thus have an impact on food for their predators (such as fish) as well as impact fish eggs and larvae (ichthyoplankton) with potential local impacts on species important in fisheries. This damage to zooplankton over 1km away from the survey array raises concern that a 500m buffer for other animals that are unable to move away from the sound, is far too small to ensure that damage is not inflicted (even if they were able to evade it).
- The impact on fish assemblages is difficult to interpret, due to multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. A global review of the effect of seismic activities on fish and invertebrates acknowledged the limits

1.5.k

FCO

of the current research due to experimental designs used or due to the focus on single species during investigations. A key concern is a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys that have been previously identified may be reflective of underestimation or overestimation and would depend on the type of interaction (synergistic, additive, or antagonistic).

- In South Africa, since October 2021, thousands of dead and/or dying Cape fur seals (*Arctocephalus pusillus pusillus*), have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. It is of concern that although the cape fur seal population within South Africa is relatively healthy, they too are under pressure from various anthropogenic pressures. Additional stress from seismic activity at this time is inadvisable.
- While "Soft starts" mitigation for seismic impacts are likely to reduce the impact for highly mobile large animals, this is unlikely to be adequate for the many species that are prevalent in the area over the austral summer months and are unable to avoid the array or leave the area due to their lower mobility, such as smaller turtles, penguins, invertebrates, some fish species and zooplankton.
- The finding of observer efficiency (from a scientific monitoring study conducted during the 2018/19 and 2019/2020 seasons on the humpback whales on the east coast) suggests that even with trained observers up to 44% of humpback whales in an area went undetected. This casts doubt on the effectiveness and success of Marine Mammal Observer (MMO) sightings of the largest species (humpbacks) as a mitigation measure, indicating that it is most likely that whales go undetected. Furthermore, the detection rate for smaller species, such as dolphins, seals, turtles and flightless birds (penguins), would be expected to be much lower, obviating the effectiveness of visual observations to prevent harm to these species.
- Also of concern, is that the efficacy of Marine Mammal Observers (MMO) is likely to be low due to the nature of the offshore marine environment in the survey area (frequent high swells and

15.12

FUB

winds affecting surface visibility), putting species who are missed by MMO's and PAM operators at extreme risk, particularly at night or during adverse weather conditions.

- Furthermore, the reliance on Observers to do visual sightings to supplement the PAM monitoring during the day, as a mandated mitigation measure, necessitates that we question the acceptability of continuing with survey activities at night. If the visual observations are useful (perhaps sighting large animals around 65% of the time) in addition to PAM, then relying on PAM alone at night cannot be an effective mitigation measure. It is our opinion that surveys should not occur between sunset and sunrise each day if a genuine attempt of maximum avoidance of cetaceans is the objective of this mitigation measure.
- It is of our opinion that the proposed seismic survey activities are highly likely to both disturb and have an adverse effect on Marine Protected Areas (MPA), Critical Biodiversity Areas (CBA) and Ecologically or Biologically Significant Areas (EBSAs), and their associated fauna, situated adjacent to, within and surrounded by the reconnaissance permit area. The reconnaissance permit area occurs adjacent to six Marine Protected Areas and surrounds a seventh (Benguela Muds MPA). In the EMP, there is no reference or provision made regarding buffer areas around these protected areas or for areas identified with biological importance and significance. Therefore, it is assumed that the vessel can actively work within 1 km of the MPA boundaries, while ignoring EBSA's and CBA's altogether, thus giving no consideration to the biological importance of these areas or the likely impact at such close range. Although 2D surveys are proposed for these adjacent areas, the cumulative zone of impact for Permanent Threshold Shift (PTS) and Temporary Threshold Shift (TTS) for physiological injury is between 500 - 5000m respectively.

Global context – impacts of seismic surveys on marine wildlife

Despite seismic surveys having been undertaken for decades in South African waters, together with the knowledge that some impact to marine fauna does indeed occur[1], there remains very little

[1] https://jncc.gov.uk/our-work/marine-mammals-and-noise-mitigation: "to reduce the risk of deliberate injury to marine mammals".

1.S.K

5/28

scientific research on the effects of seismic surveys, and in addition there are no legislated guidelines for seismic surveys in South African waters (Pardon 2016). Globally, seismic surveys' environmental impacts and consequences are slightly better documented, although not uniform in results or widely accepted within all sectors. The primary mitigation measures for seismic surveys in South Africa include soft-starts, which is a gradual and systematic increase in power of the airgun array undertaken to warn and drive mobile marine species, such as cetaceans (whales and dolphins), seals, flightless birds and turtles away from the sound source before the full-power airgun blasts begin, thus attempting to minimise the negative effects of the airgun blasting activity. Various studies contest this assumption (McCauley et al. 2000; Weilgart 2013; Dunlop et al. 2016) and have revealed a growing concern for animals that are unable to avoid or out-swim the airgun arrays.

Animals use sound critical to their life cycles (Jasny et al. 2005) in three ways, by actively producing sound (Tyack 1981), by listening to sounds emitted by other living organisms (Clark et al. 2009, Van Opzeeland 2010), and taking cues from physical or non-living factors producing sounds, contributing to the ambient background noise, such as wind, waves, swell, bubbles, currents, turbulence, earthquakes, rainfall, ice cracking or breaking (Hildebrand 2005). Many marine animals produce sound for communication, reproduction, aggression, defence mechanisms, antagonistic interactions, courtship, group coordination, orientation, navigation, and prey identification (Hildebrand 2006). They rely on producing a sound that is heard while hearing a sound and interpreting the sound for their survival.

Various physical responses to acoustic disturbance have been documented, with physical responses including soft tissue damage (Balcomb and Claridge 2001), embolisms (Dolman and Simmonds 2005), damage to organs used in balance (André et al. 2011), concussions in penguins (Cooper 1982), haemorrhaging (Evans et al. 2001) and decompression sickness (Fernández et al. 2005). Hearing impairment in the form of Temporary Threshold Shift (TTS) or Permanent Threshold Shift (PTS) has also been reported (Hildebrand 2009). Threshold shift refers to an increase in the minimum sound level required for an animal to hear a sound. A TTS is followed by successful recovery to normal

hearing thresholds after a given period of time in the absence of that sound, while PTS is when the sensory hair cells in the inner ear are permanently damaged and lost making recovery impossible (Weilgart 2013).

Stress caused by disturbance is associated with a change in body chemistry (Jasny et al. 2005) and can be equally disruptive as physical damage. Stress has implications on sexual maturation, inhibits growth, reproduction and general survival ability (Pickering 1982; McCormick 1998; Constan et al. 2001). Perceptual effects can occur when there is an interference of sounds of interest to a specific animal but are being drowned out or masked by anthropogenic noise. The impact of this in the long term could have implications on breeding populations, thus on reproduction within a population (Erbe 2001). Many animals may have the ability to counteract this and make minor changes to their vocalisations and behaviour; however, these modifications may come at a cost in terms of energy expenditure (Tyack 2008) and are likely to reduce breeding productivity of the population. This is of particular concern for species that are threatened.

Behavioural responses to noise are dependent on various factors, such as age, sex, presence of offspring, location and an individual animals' previous encounter with a specific sound or noise. Behavioural responses may include modification of vocal behaviour, displacement from important habitats, and other subtle responses, including increased breathing rates, change in dive duration, time spent at the surface, rapid or erratic movements (Bowles et al. 1994; Lesage et al. 1999; Williams et al. 2002; Nieste et al. 2003; Ng and Leung 2003; Aguilar de Soto et al. 2006). These all with potentially high energetic costs (Williams et al. 2006; Koper and Plön 2012).

Most scientific research on the impacts of seismic surveys has been conducted on odontocetes, and as a result, most mitigation measures are to protect these animals. In South Africa, this is no different. However, it is becoming more and more evident that mitigation measures are not adequate (Weilgart 2013). In the Gulf of Mexico, it was recorded that ~250 male fin whales appeared to stop singing for several weeks to months during a seismic survey. These animals resumed singing within hours or

days after the survey ended (IWC 2007). The assumption is that male fin whales use vocalisations for reproduction by finding and attracting mates (Croll et al. 2002); it can only be assumed that such an effect would be biologically significant (Weilgart 2013). In addition to this, a blue whale ceased calling in the presence of a seismic survey at 10 km away (Macdonald et al. 1995). Conversely, a different group of blue whales appeared to have the opposite reaction. They changed their vocalisations (De Lorio et al. 2010) by calling consistently more on days when the seismic surveys were actively ongoing, suggesting that seismic survey noise interfered with important signals used in their social interactions and feeding (De Lorio et al. 2010).

Other reactions to seismic airguns can be subtle or hard to detect (Weilgart 2013) and it has been found that Sperm whales in the Gulf of Mexico did not appear to avoid a seismic airgun survey area but reduced their swimming effort and their tendency to reduce foraging effort (Miller et al. 2009). It has also been documented that as a result of changes in behaviour, the result could be lower reproductive rates and have negative consequences for the population (Miller et al. 2009). In comparison, bowhead whales showed no avoidance or change in vocalisations in the area of seismic surveys; however, their dive duration was shorter (Richardson et al. 1986). In Brazil, a reduction in cetacean species diversity during 2000 and 2001 was noted with the increased occurrence of seismic surveys in the area being implicated in the possible cause of these animals vacating the area (Parente et al. 2007). In other areas, marine mammals have been recorded to avoid seismic noise by leaving an area (Castellote et al. 2012; Weir 2008; Stone and Tasker 2006). The long-term impacts of various changes in behaviour is largely unknown but potentially impact their ability to feed and/or reproduce as in some species, these life-history stages are site or habitat-specific.

South Africa's south and west coasts are home to eight species of beaked whales (Ziphiidae) (Best 2007), including a new species described in 2021 (*Mesoplodon eueu*; Carroll et al. 2021), which are globally recognised as being sensitive to anthropogenic noise, and having raised conservation concerns. New et al. (2013) found that adult female beaked whales could survive but not reproduce in times or areas of lower habitat quality. They may extend the duration of lactation in mediocre

conditions to increase their chance of survival, while still reproducing. New et al. (2013) found that some beaked whale species require high-quality habitat to meet their requirements for reproduction and survival. They suggested that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.

McEwen and Wingfield (2003) suggested that all organisms must gather energy for growth and reproduction throughout their life cycle and that organisms must retain reserves for predictable changes such as seasons, and challenges that are less predictable such as disturbance, predation pressure, or social conflict. Often colloquially, this is referred to as the "fitness" of the animal. The accumulated cost in the balance between energy intake and demand is called the 'allostatic load', of physiological and behavioural mechanisms that enable allostasis or adaptation to these changes. McEwen and Wingfield (2003) use the word "allostasis" to signify mechanisms that allow an organism to regain equilibrium while dealing with external challenges: if energy demand is more than intake, then animals may activate a survival mode that may increase energy available, reduce energy demand, or both, to regain its energy balance. Implications on individuals and populations of this energy imbalance are unknown.

Several studies have reported negative impacts of acoustic signals from airguns on zooplankton (small, aquatic microorganisms living in the water column, including crustaceans, larvae, juvenile fish, juvenile invertebrates, eggs etc.) from more than 10m away (Kostyuchenko 1972; Kosheleva 1992; Parry *et al.* 2002) with some laboratory experiments on lobster larvae showing no impact at all (Day *et al.* 2016). However, Christian *et al.* (2003), showed retardation in some individuals in the development of snow crab eggs after being exposed to certain sound levels.

The effects of seismic noise on zooplankton were brought under the spotlight when McCauley *et al.* (2017) presented evidence from an in-situ study that suggested that seismic surveys cause significant mortality to zooplankton populations. Zooplankton, unlike vertebrates, do not have hearing structures (although they can sense pressure change) and their bodies are generally the same density as the

surrounding water, so sudden pressure changes associated with seismic activities were presumed not to cause physical damage (Parry and Gason 2006). McCauley *et al.* (2017) disputed this and has shown zooplankton mortality at distances of up to 1.2km from the sound source.

Similarly, inconsistent findings occur with fish assemblages. The impacts on fish assemblages are difficult to interpret, because of multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. We acknowledge the validity of the results presented by Meekan et al. (2021) which highlights that exposure to an experimental seismic source did not have an impact on the assemblage of tropical demersal fishes found along the northwest shelf of Western Australia. However, it must be noted that the findings have been stated to be applicable only to other habitats with similar physical environments, in particular similar water depths (50 – 70 m). The proposed reconnaissance permit area on the south and west coasts of South Africa differs significantly from those reported in the Meekan et al. (2021) research, thus highlighting the need for South African-specific and local research to be undertaken.

A global review of the effect of seismic activities on fish and invertebrates by Carroll et al. (2017) acknowledged the limits of the available research due to experimental design, or to the focus on single species which prevents extrapolation to other regions, other seismic surveys, species, or biological responses. In addition, they highlighted a serious concern, that there was a lack of research focused on confounding effects and multiple stressors. Therefore potential impacts of seismic surveys which had previously been identified may be reflective of under-estimation or over-estimation and would depend on the type of interaction (i.e. synergistic, additive, or antagonistic).

Furthermore, the indirect effects of seismic activity on cetaceans is a concern. It is well known that the productivity and health of the oceans are under-pinned by marine plankton (Raymont 1983; Alcaraz & Calbet 2009). While forming the basis of the food webs, plankton has been implicated in links to climate change via their role in iron fertilisation and carbon sequestration through whales foraging on krill and subsequent defecation (Smetacek and Nicol 2005; Smetacek 2006; Nicol et al.

2010). In 2010, Pershing et al. suggested that over-fishing of large fish and commercial whaling had compromised the ocean's ability to store and sequester carbon, thus contributing to climate change. They indicated that populations of large baleen whales now store 9.1×10⁸ tonnes less carbon than before commercial whaling and that protecting whales (and other large over-exploited species), would be a form of a carbon management scheme. The cascading and knock-on effects of seismic survey impacts between the upper (cetaceans) and lower reaches (plankton) of the food web, as each are being impacted are unknown. McCauley et al. (2017) noted that the ramifications of compromised larval recruitment could be massive for higher predators and for ocean health as a whole. While traditional feeding grounds for humpback whales are in Antarctic waters, Dey et al. (2021) has recently recorded regular feeding frenzies off the west coast in recent years (see super pods below)

South Atlantic Context

It is of concern that there are a number of 'unknowns' and 'warning bells' in terms of cetacean populations on the south and west coasts. Despite various species being recorded frequently on the coasts, the location of breeding grounds of Bel (Balaenoptera borealis) and Fin whales (*Balaenoptera physalus*) are unknown, the seasonality of pygmy (*Kogia breviceps*) and dwarf (*Kogia sima*) sperm whales are unknown and the abundance and occurrence of the offshore common dolphin (*Delphinus delphis*) is also unknown, highlighting that encounters with these animals cannot be predicted and the generic mitigation measures may be insufficient. Further to this, it is noted in the EMP submitted by Searcher that the two very well-studied and frequently observed species on the south and west coasts, the humpback and southern right whales, *are expected to be regularly encountered and have a year-round occurrence across the entire reconnaissance permit area*. The period of humpback whales in this area is between July and February, with frequent feeding encounters during the months between December to February. Barendse et al. (2010), Best & Allison (2010), and Elwen et al. (2014) highlighted that there is no existing evidence of a clear 'corridor' of migration and humpback whales appear to be spread out widely across the shelf and into deeper pelagic waters, especially during the southward migration, in the Benguela ecosystem.

Further to this, the EMP itself highlights that, "*It is highly likely that several hundreds of right whales can be expected to pass through the Reconnaissance Permit Area when migrating southwards from the feeding areas between April and June*" (page 93). Apart from this going against the spirit of avoiding whale periods by the oil and gas industry, Vermeulen et al. (2020) warned that there is an observed decrease in southern right whale calving success of the South African population and a strong link between foraging success and reproduction. They suggest an investigation into possible decreases and/or spatial or temporal shifts in their prey availability at higher latitudes due to environmental variability. They also highlight a concern of the continued low numbers of unaccompanied adults along the South African coast which could potentially have serious consequences for cow-calf pairs in relation to the country's whale-watching industry in the future.

Since 2011, South Africa has witnessed 'super-pods' of up to 200 humpback whales feeding in south and west coast waters between October to January. Research by the National DFFE, in collaboration with various academic partners, has led to the discovery of these 'feeding grounds' away from their traditional feeding grounds in the Antarctic[2]. This phenomenon requires understanding the ecosystem-wide impacts and benefits, while potential human/whale conflicts remain unknown. According to Day et al. (2021), the formation of super-groups in recent years suggests that there might be a change in oceanographic or ecological characteristics which provide the conditions for this novel feeding strategy in the Southern Benguela Upwelling System. Although the humpback whale population is increasing (Wilkinson, 2021), there is evidence to suggest that cetaceans in South African waters are being affected by changes in their ecosystem and it is not well understood yet what is driving these changes and what the long terms effects could potentially be to populations.

With other mammals, it was suggested by Thompson et al. (1998) that grey seals displayed strong avoidance behavior, altered foraging behavior and suggested an increased frequency of hauling out

[2] https://www.news24.com/news24/southafrica/news/super-pods-of-humpback-whales-spotted-off-south-africas-west-coast-20210126

onto land to possibly escape the noise, while harbor seals had slower heart rates during controlled playback experiments. In contrast, during a study in shallow arctic waters, sighting rates of ringed seals (*Phoca hispida*) from a seismic vessel showed no difference when a different number of airguns were in use, did however suggest local avoidances based on distance from the sound source (Harris et al., 2001).

In South Africa, the Cape fur seals (*Arctocephalus pusillus pusillus*), is the only resident seal along the west coast, occurring at numerous breeding and non-breeding sites on South Africa's mainland and on nearshore islands and reefs. Other vagrant seals occurring along the south and west coast include the southern elephant seal (*Mirounga leonina*), subantarctic fur seal (*Arctocephalus tropicalis*), Antarctic fur seal (*Arctocephalus gazella*), crabeater (*Lobodon carcinophagus*) and leopard seals (*Hydrurga leptonyx*). Cape fur seals are highly mobile and have large foraging areas including on the continental shelf up to 120 nautical miles offshore (Shaughnessy 1979).

According to Kirkman et al 2016, several morbillivirus epidemics have occurred in true seal (Phocid) populations in the northern hemisphere and, at the time it was agreed that no epidemic diseases were known to have infected Cape Fur Seals historically, but there was a considerable risk for disease transmission to the population through exposure to domestic or feral dogs and terrestrial carnivores, potentially resulting in mass mortality. Kirkman et al. (2016) cautioned that the health of individuals and their vulnerability to disease can be affected by feeding conditions, including the availability of prey, and that risk of disease may be exacerbated by anthropogenic pressures on the ecosystem.

In South Africa, since 10 September 2021, thousands of emaciated, dying and dead Cape fur seals (*Arctocephalus pusillus pusillus*), have washed ashore along the south and west coasts. The causes of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. It is of concern that although the cape fur seal population within South Africa are healthy, they too are under pressure from various anthropogenic pressures, and the EMP failed to mention this mass die-off event.

In South Africa, only a single focused study on the impact of seismic surveys has been undertaken. This study, off Gqeberha, was within the foraging area of the endangered, endemic African Penguin (*Spheniscus demersus*). Pichegru et al. (2017) demonstrated that penguins avoided their preferred foraging areas during seismic surveys and foraged further from the survey vessel when in operation. Upon termination of seismic surveys, the penguins reverted to their normal behaviour (Pichegru et al. (2017), a behaviour which was also observed in Gray whales (*Eschrichtius robustus*) off Sakhalin Island in Russia (International Whaling Commission 2008). However, the long-term effects on populations of this temporary retreat of the area are unknown. Given the results of this study by Pichegru et al.(2017), strict management measures and decisions on seismic survey activities should have been established in South Africa. Furthermore, the cumulative effect of multiple, concurrent seismic surveys within the region may cause cumulative impacts.

Significant impacts on turtle species are a concern. Adult turtles may be less vulnerable to sound damage than cetaceans as the air spaces in their cochlear are smaller than those in cetaceans, making them less sensitive to sound shockwaves (Popper et al. 2014). However, while studies have shown that adult sea turtles have a moderate ability to move from an area being surveyed (Lenhardt 1994; O'Hara and Wilcox 1990), they are prone to TTS after exposure to sound within 1 km of a sound source, with signs of recovery only two weeks after injury (Lenhardt 1994). In a study undertaken on captive turtles, it was found that loggerhead turtles (*Caretta caretta*) responded to sound by swimming to the surface and remaining there or staying slightly submerged (Lenhardt 1994), as this area, regarded as a sound shadow, and is hypothesised as being where sound waves cancel each other out and the noise is at a minimum. Cummings et al. (2004) disputed this saying that although near the surface, could be a place where animals take refuge, they are not in a 'zone of silence'. With an increasing exposure of sound levels, the behaviour of caged green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) turtles increased their swimming speed, potentially showing agitation to sound (McCauley et al. 2000). Turtle behaviour is difficult to interpret (DeRuiter and Doukara 2012), given that some studies have reported that turtles do not display any signs of distress (Pendoley 1997).

15k

Globally the Leatherback turtle (*Dermochelys coriacea*) is vulnerable, but critically endangered in the Southwestern Indian Ocean where this subpopulation is declining (Nel 2010, 2012; Nel et al. 2013). Loggerhead (*Caretta caretta*) populations are globally vulnerable but near threatened in the southwest Indian Ocean (Lombard & Kyle 2014).

The nesting grounds of the southern African loggerhead (*Caretta caretta*) and leatherback turtle (*Dermochelys coriacea*) populations are located on the east coast in iSimangaliso Wetland Park. In the Autumn months, adult turtles are moving towards their nesting beaches but stay inshore to avoid the north to south flowing Agulhas current. Once they have completed their laying of eggs, they leave the shore and into the current to be carried south once again, and by late March, they will be filtered along the east and south coast in offshore waters. Both loggerhead and leatherbacks are known to occur within the reconnaissance permit area but known migration corridors of adult leatherbacks lie within the reconnaissance permit area. Harris et al. (2018) highlighted the migration path for leatherback turtles into the southeastern Atlantic (Agulhas-Benguela Corridor), through the reconnaissance permit area. Leatherback turtles inhabit deeper waters and are considered a pelagic species, travelling within the ocean currents. However, they have a moderate ability to avoid areas with an increase of noise in the water. According to Hays et al. (2004), these animals may dive to depths over 600 m and remain submerged for up to 54 minutes. Mitigation measures for turtles in seismic surveys include observers, although it is unclear how an observer would be able to observe these animals at such a distance (especially as large animals such as whales are only observed 44% of the time at best). A second mitigation measure, although only to be used if turtles are sighted by observers (EMP page 234), is to install 'turtle-guards' to prevent them from becoming entangled in the gear. These devices are accepted as being useful in terms of entrapment but not for sound in the water. Given the sighting probability of a turtle by an observer is minimal (as explained above) and that turtle guards are not a standard measure on the gear for this survey, these two mitigation measures are hardly justifiable.

Effectiveness of Mitigation (Marine Mammal Observers (MMO) and Passive Acoustic Monitoring (PAM))

During the 2018 and 2019 humpback whale (*Megaptera novaeangliae*) migration period along the east coast of South Africa, Wilkinson (2021) estimated the relative abundance of migrating humpback whales sighted by trained observers from two towers located 22m apart (both observers viewing the same area), located at 70m above sea level on a dune with a horizontal vantage length of approximately 20 km. Over the observation periods during the peak of migration, it was estimated that observers from both towers missed between 41-44% of whale groups while distance offshore decreased the probability of sightings. Assuming that the best percentage sighting (56%) was achieved within 1-5km of the observers' vantage point, then more than 90% of whales were missed. Given that this survey was done during the northward migration when mostly larger animals are present, the sighting success may be less when small calves are present as well (as would be the case in December). This begs the question of the efficacy and reliability of the mitigation method of Marine Mammal Observers (MMO), while assuming that whales (and other cetaceans) are thus regularly missed by MMOs and could be harmed.

Despite various organisations who provide MMO's on vessels having a zero tolerance policy of intimidation it is not uncommon for an MMO to complain that he/she has been subjected to coercion, harassment and intimidation. The EMPr states that: "*The MMO has the authority to stop the survey activities (including seismic shooting) in response to certain circumstances related to marine mammal risk. However, due to the cost associated with terminating activities (e.g. an entire survey line may need to be repeated), it is recommended that the decision to terminate firing be made by the operator in consideration of the MMO's advice. The MMOs must provide full reporting of all termination decisions (including behaviour and distance of marine mammals) in a daily close out report (Part B, p.8)*". This statement is highly problematic and reinforces the concern that "A risk-averse and cautious approach, which takes into account the limits of current knowledge about the

consequences of decisions and actions", a principle of the National Environmental Management Act, 107 of 1998, will not be applied in full.

Furthermore, bearing in mind the examples above, i.e. blue and fin whales ceasing to sing, the use of Passive Acoustic Monitoring (PAM) technology to detect cetaceans is baseless if cetaceans do not vocalise. As per best practice, in an effort to improve mitigation, PAM technology is complemented by visual searching over an area of 500m around the vessel by qualified Marine Mammal Observers (MMO). This technique is, however, also fatally flawed because it cannot be used at night, during rain and in sea states more than three on the Beaufort Sea State Scale. Therefore, both PAM and MMO's are insufficient to detect, with certainty, cetaceans within the surrounding survey area and these types of mitigation will only be effective for all affected species if airgun firing ceases between sunset and sunrise, and adverse weather conditions that limit visibility.

The cumulative and long-term effects of seismic survey sound is not entirely understood (Jasny et al. 2005); however, it is accepted that ocean noise may have ecosystem-scale effects (Hildebrand, 2005) and the "knock-on" effects on animals, their prey and their predators will have consequences within the food chain (Koper and Plön 2012). It has been suggested that research and a critical review on mitigation measures (McCauley et al. (2017) as well as a better understanding of ecosystem-scale effects of sound (Koper and Plön 2012), especially at the lower trophic levels are imperative. Considering the ecosystem services provided by the Benguela Current Marine Ecosystem and its associated diversity and biomass, mitigation and understanding should be a conservation imperative in South African marine waters. Up to now, there has been no effort in increasing the knowledge of the impact of these seismic surveys by industry or South African environmental departments despite them being known to have impacts on marine animals and having been undertaken in South African waters for a number of decades.

Proximity to Marine Protected Areas and Critical Biodiversity Areas

The reconnaissance permit area occurs adjacent to six Marine Protected Areas (MPAs) including the Orange Shelf Edge MPA, Child's Bank MPA, Benguela Muds MPA, Cape Canyon MPA, Robben Island MPA and the Southeast Atlantic Seamounts MPA and completely surrounds the Benguela Muds MPA (See EMP: Figure 7-20). It is a significant concern that there is no reference or mention of buffers-areas around the MPAs in the EMP, which allows the vessel to come within 1 km of these protected areas. This is of particular concern, given that the EMP indicates *the cumulative zone of impact for the 3D survey extends to 600 m for permanent threshold shifts (PTS) and to 8 000 m for temporary threshold shift (TTS) for physiological injury, and the cumulative zones for PTS and TTS while the 2D survey is 500 m and 5 000m, respectively.* For example, the reconnaissance permit allows the survey vessel to be active ~600 m from the edge of the Orange Shelf Edge MPA, which is designated as a sanctuary zone, at depths of 250-1500m. Therefore, this would be within the zone of TTS and very near to that of PTS for 2D surveys.

It should be noted that, according to the National Environmental Management: Protected Areas Act 57 of 2003: section 48A reads:

"*48A Restriction of activities in marine protected areas:*
Despite any other legislation, no person may in a marine protected area-
...
(e) in any manner which results in an adverse effect on the marine environment, disturb, alter or destroy the natural environment or disturb or alter the water quality or abstract sea water;
(f) carry on any activity which may have an adverse effect on the ecosystem of the area;...."

While it is acknowledged that the EMP states that only 2D seismic activities will take place near any MPAs, it cannot be ignored that the proposed seismic activity will still have potential adverse effects on the ecosystem within the area and disturb the natural environment.

Further to this, large portions of the reconnaissance permit area comprise of Critical Biodiversity Areas (CBA) both 1 and 2 (See EMP: Figure 7-21). CBA 1 areas are irreplaceable or near-irreplaceable, while CBA 2 are sites that are the best option available for representing the features in a spatial prioritisation (Harris et al. 2020). The primary of objective, and national policy, is that both CBA 1 and

W.S.K

F100

2 areas remain in natural or near-natural states for conservation management, while portions of these areas be set-marked for future MPAs.

Curriculum Vitae

JEAN MARY HARRIS

PERSONAL DETAILS

Name	:	Jean Mary Harris
Birth date	:	28 December 1962
ID Number	:	6212280006088
Place of birth	:	Johannesburg
Nationality	:	South African
Race	:	White
Gender	:	Female
Address	:	49 Retford, Bluff, Durban, 4052, KZN South Africa
Tel	:	+27-61-4219688 (w), 082-4954416
e-mail	:	jeanh@wildtrust.co.za or jmharris@iafrica.com

EDUCATION

1993 PhD (Zoology), University of Cape Town. Focus: Trophic ecology in estuarine and intertidal systems.
1984 B.Sc. Hons. (Marine Biology), University of Cape Town, First Class
1982 B.Sc. (Zoology), University of Cape Town
1979 Matriculated, A-grade, Clarendon Girls High School, East London

AWARDS:

- PEW Fellowship in Marine Conservation, 2000
- Purcell Memorial Prize for best Zoology PhD thesis, 1993
- FRD Special Merit Doctoral Award, 1990

SELECTION OF PROFESSIONAL OFFICES HELD

Pew Fellow in Marine Conservation, Pew Fellows Program in Marine Conservation, 2000 - present
Trustee: South African Association for Marine Biological Research, 2016- July 2017
Member: Programme Steering Committee for the Marine Science for Management Association (MASMAA), Western Indian Ocean Marine Science Association (WIOMSA) 2004-2015.
Chair: Subsistence Fisheries Task Group 1999-2000.
Chair: SA Network for Coastal and Oceanographic Research (SANCOR) National Steering Committee 1997-2001.
Member: IUCN Species Survival Commission – Marine Conservation Committee, 2018-present
Member: IUCN SSC Red List Committee, 2018-2021
Executive Trustee: Wildlands Conservation Trust, 2015- April 2017
Member: Scientific Authority 2014-2017. Advises the SA Minister of Environment on biodiversity matters
Chair: Symposium of Contemporary Conservation Practice (SCCP) 2012- July 2017.
Member: East African Marine Ecoregion Programme Committee (EAME) 2004-2010

EMPLOYMENT RECORD

Executive Director WILDOCEANS, Wildlands Conservation Trust, August 2017 - current
Research Associate, Institute for Coastal and Marine Research, Nelson Mandela University, 2016-present
Senior General Manager: Scientific Services, Ezemvelo KZN Wildlife, October 2006 – July 2017
Ecological Advice Co-ordinator, Coast Region, Ezemvelo KZN Wildlife, 2002 - September 2006
Regional Ecologist Marine/Scientist, Scientific Services, KZN Nature Conservation Service, 1995 – 2002
Senior Scientific Officer, Terrestrial Antarctic Biology Research Programme, Ornithology, UCT, 1991-1994

SELECTION OF RESEARCH AND MANAGEMENT EXPERIENCE

Project Leader Blue Action Fund "Oceans Alive" iSimangaliso MPA Project (2019-current): This project has 3 main objectives 1) Build knowledge of the biodiversity and socio-economics of the MPA and its communities, 2) Support effective management of the iSimangaliso MPA, and 3) Ensure benefits and improved livelihoods for rural communities living alongside the iSimangaliso MPA.

Directs the following WILDOCEANS projects for the Wildlands Conservation Trust (2017-current): Ocean Stewards, WhaleTime, MPA Expansion Project, Shark and Bay Conservation Project, Comoros Fish and Benthic Biodiversity Project, iSimangaliso Oceans Alive (MPA expansion, effective management and benefits to communities) Project, Blue Crew project in the Durban bay estuarine environment (plastic pollution action).

Principle investigator and Co-ordinator for NRF-funded African Coelacanth Ecosystem Programme research projects: Biodiversity Surrogacy (2014-2017), Spatial Solutions (2016-2018) and Canyon Connections (2018-2020). Offshore biodiversity survey and sampling to test validity of modelled biozones, to refine conservation planning, and to support marine protected area expansion and the National Biodiversity Assessment (CBD).

Project leader for WWF-SA, NRF and ACEP funded project: SeaPLAN – development of a systematic conservation plan for the east coast of South Africa (2004-2012). Integrates shoreline biodiversity mapping, reef biodiversity surveys and key species and processes.

Project leader Wildlands Trust funded project: Rare and Endangered Species of the Greater St Lucia Wetland Park (2002-2005). This project aims to update the records of these species in the park and provide a management handbook. It is focussed on terrestrial and freshwater wetland species and employs a full-time researcher. This project has become entrenched and is ongoing.

Project leader for NRF funded project: KwaZulu-Natal and Transkei Indigenous knowledge of subsistence harvesters (2002-2006). Aims to document traditional knowledge and management systems of rural subsistence harvesters, compare regional differences, and integrate into current management practices.

Chairperson of Subsistence fisheries Task Team, on behalf of Marine and Coastal Management (DEAT), managed a national programme for coast-wise identification of and consultation with subsistence fishers (1999-2000). Acted as Program manager and supervisor of 8 Regional Fieldworkers (Northern Cape, West Cape (x2), South coast, Eastern Cape (x2), KwaZulu-Natal (x2), and a National Co-ordinator and project researcher. – Project leader and finance vote-holder (ca R1 mill)

Project executant (co-ordinator & researcher, and supervisor of 2 project staff) for 5-year project funded by The Green Trust, WWF-SA: The development of sustainable utilization of mussels by artisanal and subsistence gatherers along the northern KwaZulu-Natal coast – Sokhulu community alongside iSimangaliso 1995-2000.

1-5 K

POST-GRADUATE STUDENT SUPERVISION:

6 MSc and 2 PhD students

PUBLICATION SUMMARY:

Papers in refereed journals:	37
Book/ book chapter	8
Reports and Popular articles	10

Searcher Seismic Reconnaissance Project

Social Impact Assessment

Prepared by:

Equispectives Research & Consulting Services

Contact person: Ms San-Marié Aucamp

Dr Ilse Aucamp

Prepared for:
EIMS

September 2022

Executive Summary

Searcher Geodata UK Ltd proposes to undertake a 3D seismic survey off the West Coast of South Africa. The proposed project area is located approximately 256 km offshore of St Helena Bay, extending north along the western coastline to approximately 220 km offshore of Hondeklip Bay over a number of petroleum license blocks. At the closest point the proposed survey area is approximately 218 km offshore of the coast of the Western and Northern Cape provinces. The area of interest for the proposed 3D seismic survey is approximately 30 000 km^2 in extent.

Searcher's activities for this application would be of short duration if approved, and if viewed in isolation considering only technical risks as discussed in various specialist reports conducted as part of the EIA process, the impacts will be negligible. However, communities feel that there are significant gaps in the available data and from a social perspective the non-technical or social risks can potentially cause significant impacts. The following potential social impacts have been identified:

- Uncertainty
- Further marginalisation of vulnerable groups
- Concerns about cumulative impacts
- Impact on livelihoods
- Impacts on sense and spirit of place
- Impacts on the social licence to operate
- Community expectations
- Social unrest

Seismic reconnaissance projects are controversial in South Africa and has been in the news frequently in the last year. For many stakeholders it is an emotional matter, for others the potential of impacting their livelihoods is the biggest fear. There are also

stakeholders that feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change. Other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. It is a complex and wicked[1] problem.

Based on the findings, the following recommendations are made:

- Searcher should develop a community engagement protocol, communication strategy and grievance mechanism that is based on the San Code of Research Ethics.
- Searcher should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. Collaboration across seismic operators with holders of hydrocarbon exploration and the industry as a whole to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study. This would quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in South African Waters.
- Consult with communities on potential ways in which to make a positive contribution to the communities.
- Engage in meaningful consultation
- The seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign.

From a social perspective it is clear that the communities and majority of local people are opposed to the project. If the project is considered in isolation, the impacts are negligible. However, the project does not happen in a vacuum, and the social environment is much wider than the footprint of the project. If the social risks and

[1] a wicked problem is a problem that is difficult or impossible to solve because of incomplete, contradictory, and changing requirements that are often difficult to recognize.

5628

potential damage to cultural and indigenous rights are considered the impact on the social fabric of already vulnerable communities may be significant. From as social perspective the project can only be recommended after meaningful consultation, local research, education, and awareness raising has been done in the project affected communities. At this stage communities feel that they cannot make informed decisions. Communities does not distinguish between the different role players in the seismic survey industry. Although all legal processes have been followed by Searcher, the seismic survey industry is not moving at the pace of the community, and in the long run this will be detrimental to the industry. Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed. The recommendation is therefore that the project can only proceed once the social mitigation measures have been implemented and the community are sufficiently informed and educated to able to engage in a meaningful manner.

Opsomming

Searcher Geodata UK Ltd beoog om 'n 3D seismiese opname te doen aan die Weskus van Suid-Afrika. Die voorgenome projek area is ongeveer 256 km van St Helena Baai in die diepsee geleë, en strek dan Noord teen die westelike kuslyn af tot ongeveer 220 km in die diepsee in vanaf Hondeklipbaai oor 'n aantal petroleum lisensie blokke. Die punt wat die naaste aan die land is, is ongeveer 218 km in die diepsee aan die kus van die Wes Kaap en die Noord Kaap Provinsies. Die gebied wat die voorgenome 3D seismiese opname beplan om te dek beslaan ongeveer 30 000 km^2.

Searcher se aktiwiteite vir hierdie aansoek sal van korte duur wees indien dit goedgekeur word, en wanneer dit in isolasie beskou word en slegs die tegniese risiko's oorweeg word soos wat bepreek is in die onderskeie spesialis studies wat gedoen is as deel van die omgewingsimpak assessering proses is die impakte gering. Die betrokke gemeenskappe voel egter dat daar betekenisvolle gapings in die beskikbare data is en van 'n sosiale perspektief kan die nie-tegnies of sosiale risiko's potensieel betekenisvolle impakte veroorsaak. Die volgende sosiale impakte is geïdentifiseer:

- Onsekerheid
- Verdere uitsluiting van weerbare groepe
- Bekommernisse oor kumulatiewe impakte
- Impak op vermoë om 'n lewensbestaan te maak
- Impakte op sin en gees van plek
- Impakte op die sosiale bedryfslisensie
- Verwagtinge van die gemeenskappe
- Maatskaplike onrus

Seismiese verkenningsprojekte is kontroversieel in Suid Afrika en was dikwels in die nuus die afgelope jaar. Vir baie belanghebbendes is dit 'n emosionele saak, vir ander

is die moontlikheid dat hulle lewensbestaan geaffekteer gaan word die grootste vrees. Daar is ook belanghebbendes wat voel dat die eksplorasie vir fossielbrandstowwe nie in lyn is met volhoubare ontwikkeling en die stryd teen klimaatsverandering is nie. Ander belanghebbendes voel dat dit noodsaaklik is vir die groei en ontwikkeling van die Suid Afrikaanse ekonomie om betrokke te raak by hierdie ondersoeke. Dit is 'n komplekse probleem, en 'n probleem wat moeilik of onmoontlik is om op te los.

Gebaseer op die bevindinge word die volgende aanbevelings gemaak:

- Searcher moet 'n gemeenskapsbetrokkenheid protokol, kommunikasie strategie en griefmeganisme ontwikkel wat gebaseer is op die San Kode van Navorsingsetiek.
- Searcher moet behulpsaam wees met samewerking tot onafhanklike navorsing oor hoe visspesies aan die Weskus soos snoek reageer op seismiese opnames. Samewerking tussen seismiese operateurs en houers van koolwaterstof eksplorasie regte en die industrie as 'n geheel om kollektief pro-aktiewe navorsing te befonds sal die geleentheid bied vir die ontwikkeling en implementering van 'n gestruktureerd en eksperimenteel sollede akoestiese studie. Dit sal die owerhede en belanghebbendes kwantitatief inlig omtrent die akoestiese impakte op die verskeie fauna groepe in die Suid Afrikaanse waters.
- Konsulteer met die gemeenskap op maniere waarop 'n positiewe bydrae tot die gemeenskappe gelewer kan word.
- Raak betrokke by betekenisvolle konsultasie.
- Die seismiese opname bedryf moet hulle posisie en sosiale bedryfslisensie as 'n industrie in die Suid-Afrikaanse konteks heroorweeg en 'n strategiese omgewingsassesserling van die impak van die bedryf uitvoer en 'n bewusmakings- en opvoedkundige veldtog van stapel stuur.

Vanuit 'n sosiale perspektief is dit duidelik dat die gemeenskappe en die meerderheid van die plaaslike mense gekant is teen die projek. As die projek in isolasie beskou word, is die impakte gering. Die projek vind egter nie in 'n vakuum plaas nie, en die sosiale

omgewing is heelwat breër as die voetspoor van die projek. Indien die sosiale risiko's en potensiële skade aan die kulturele en inheemse regte oorweeg word, kan die impak op die sosiale weefsel van die reeds weerlose gemeenskappe betekenisvol wees. Vanuit 'n sosiale perspektief kan die projek slegs aanbeveel word na betekenisvolle konsultasie, plaaslike navorsing, opvoeding, en bewusmaking gedoen is in die gemeenskappe wat deur die projek geraak is. Tans voel die gemeenskappe dat hulle nie ingeligte besluite kan neem nie. Gemeenskappe onderskei nie tussen die verskillende rolspelers in die seismiese opname industrie nie. Alhoewel al die wetlike prosesse deur Searcher gevolg is, beweeg die seismiese opname bedryf nie teen die pas van die gemeenskap nie, en op die lange duur sal dit tot nadeel van die industrie wees. Moontlike toekomstige voordele en ekonomiese ontwikkeling van die land indien die opnames betekenisvolle hulpbronne vind, word nie betwyfel nie. Die aanbeveling is gevolglik dat die projek slegs kan voortgaan sodra die mitigasie maatreëls geïmplementeer is en die gemeenskappe genoegsaam ingelig en toegerus is om op 'n betekenisvolle manier betrokke te raak.

Declaration of Independence

Equispectives Research and Consulting Services declare that:

- All work undertaken relating to the proposed project was done as independent consultants;
- They have the necessary required expertise to conduct social impact assessments, including the required knowledge and understanding of any guidelines or policies that are relevant to the proposed activity;
- They have undertaken all the work and associated studies in an objective manner, even if the findings of these studies were not favourable to the project proponent;
- They have no vested interest, financial or otherwise, in the proposed project or the outcome thereof, apart from remuneration for the work undertaken under the auspices of the above-mentioned regulations;
- They have no vested interest, including any conflicts of interest, in either the proposed project or the studies conducted in respect of the proposed project, other than complying with the relevant required regulations; and
- They have disclosed any material factors that may have the potential to influence the competent authority's decision and/or objectivity in terms of any reports, plans or documents related to the proposed project as required by the regulations.

Record of Experience

Ilse Aucamp and San-Marié Aucamp compiled this report.

Ilse Aucamp holds a D Phil degree in Social Work obtained from the University of Pretoria in 2015. She also has master's degree in environmental management (Cum Laude) from the Potchefstroom University for Christian Higher Education, which she obtained in 2004. Prior to that she completed a BA degree in Social Work at the University of Pretoria. She is frequently a guest lecturer in pre- as well as post-graduate programmes at various tertiary institutions. Her expertise includes social impact assessments, social management plans, social and labour plans, social auditing, training as well as public participation. She is a co-author of the newly published *Social Impact Assessment: Guidance for assessing and managing the social impacts of projects* document published by the International Association for Impact Assessment.

San-Marié Aucamp is a registered Research Psychologist with extensive experience in both the practical and theoretical aspects of social research. She has more than 20 years' experience in social research and she occasionally presents guest lectures on social impact assessment. Her experience includes social impact assessments, social and labour plans, training, group facilitation as well as social research. She is a past council member of the Southern African Marketing Research Association (SAMRA).

1 Introduction

Searcher Geodata UK Ltd proposes to undertake a 3D seismic survey off the West Coast of South Africa. The proposed project area is located approximately 256 km offshore of St Helena Bay, extending north along the western coastline to approximately 220 km offshore of Hondeklip Bay over a number of petroleum license blocks. At the closest point the proposed survey area is approximately 218 km offshore of the coast of the Western and Northern Cape provinces. The area of interest for the proposed 3D seismic survey is approximately 30 000 km^2 in extent.

Marine seismic surveys are the primary tool for locating hydrocarbon deposits and are thus a key component of offshore oil and gas exploration. Hydrocarbon deposits occur in reservoirs in sedimentary rock layers. Being lighter than water they accumulate in traps where the sedimentary layers are arched or tilted by folding or faulting of the geological layers. It is currently envisaged that the survey lines would have a NE-SW or a SE-NW orientation. The 3D survey will take in the order of 127 days including downtime.

A single survey vessel equipped with seismic sources and streamers will be used which will be supported by one escort vessel. The escort vessel will assist in monitoring for and alerting of other vessels (e.g. fishing, transport, etc) about the survey and the lack of manoeuvrability of the survey vessel. At a minimum one Fisheries Liaison Officer (FLO) that speaks English and Afrikaans will be on board either the survey or escort vessel to facilitate communication in a local language with the fishing or other vessels that are in the area. In addition, there will be two Marine Mammal Observers (MMO's) on board the survey vessel to monitor for marine mammals and fauna visually and ensure that the survey is conducted in compliance with the specified guidelines as stated in the Environmental Management Programme.

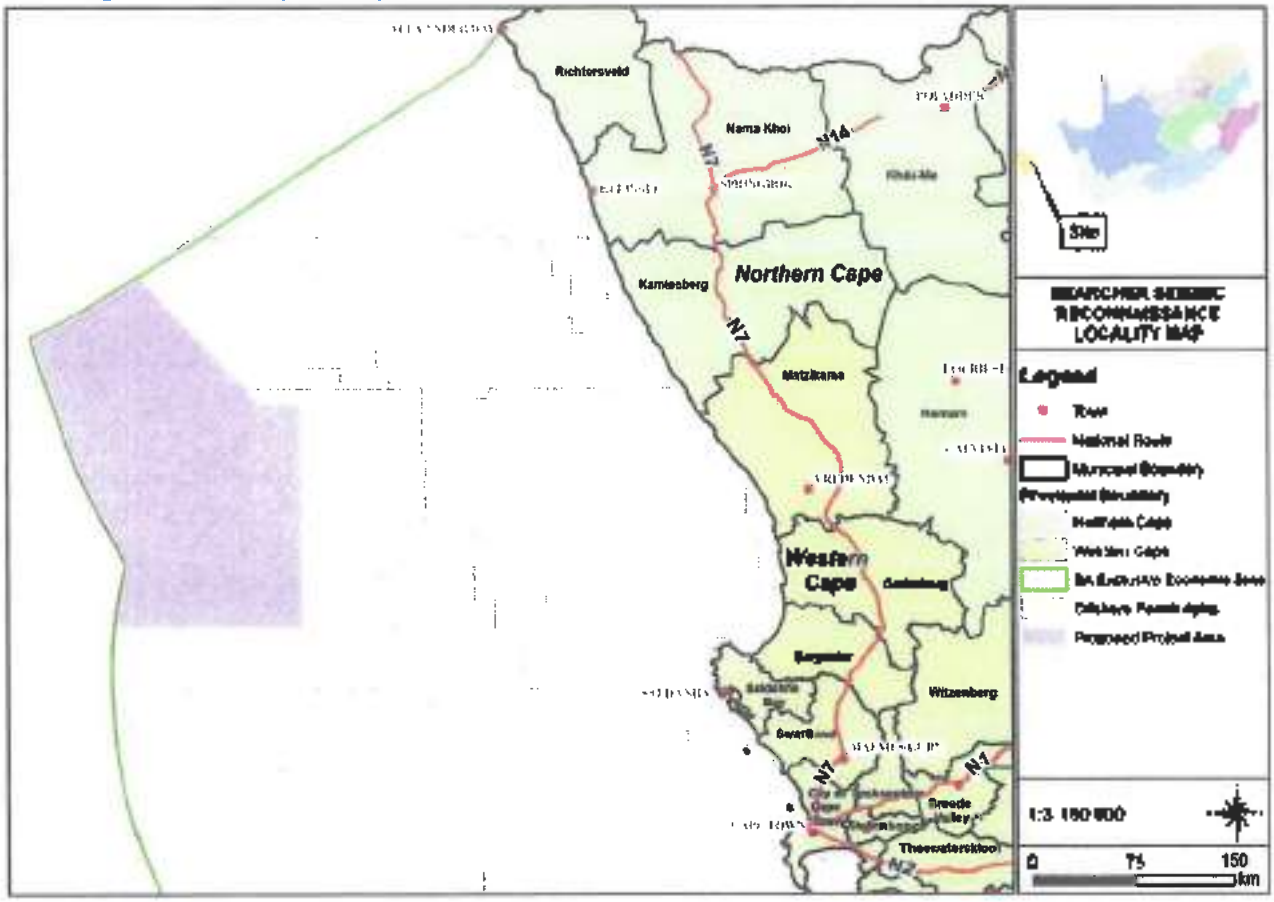
Crew changes will occur by the support or survey vessel calling to port. If necessary, a helicopter maybe used to transfer personnel to and from the survey vessel and Cape Town or Saldanha Bay. However, due to the helicopter's low carrying capability this is

5108

unlikely to occur. The onshore logistics base will be either in the Port of Cape Town or the Port of Saldanha Bay. The preferred alternative is Cape Town. The service infrastructure required to provide the necessary onshore support is already in place in Cape Town and Saldanha Bay and as such no additional onshore infrastructure should be necessary for the project.

Figure 1 shows the location of the proposed project area.

Figure 1: Locality of proposed Searcher Seismic Reconnaissance Project.



The purpose of this report is to provide baseline information regarding the socio-economic environment, to identify possible social and economic impacts and to suggest ways in which these impacts can be mitigated. This will assist decision-makers on the project in making informed decisions by providing information on the potential or actual consequences of their proposed activities. The process entailed the following:

- A baseline socio-economic description of the affected environment;

5103

- Identification of potential social and economic change processes that may occur as a result of the project; and
- Identification of potential social and economic impacts.

One of the ways in which social risk can be managed is by conducting a social impact assessment (SIA). Such an assessment can assist with identifying possible social impacts and risks. Disregarding social impacts can alter the cost-benefit equation of development and in some cases even undermine the overall viability of a project. A proper social impact assessment can have many benefits for a proposed development (UNEP, 2002) such as:

- Reduced impacts on communities of individuals;
- Enhanced benefits to those affected;
- Avoiding delays and obstruction – helps to gain development approval (social license);
- Lowered costs;
- Better community and stakeholder relations; and
- Improved proposals.

More detail on the scope of each of these phases is included in the section below.

2 Scope of Work

The purpose of the SIA is to provide input in the Environmental Impact Assessment (EIA)/ Environmental Management Programme (EMPr) Report for the proposed seismic reconnaissance study.

5128

3 Methodology

Scientific social research methods were used for this assessment. To clarify the process to the reader, this section will start with a brief explanation of the processes that have been used in this study.

3.1 Information base

The information used in this report was based on the following:

- A literature review (see list provided in the References);
- Data from Statistics South Africa;
- The public participation records provided by EIMS;
- Professional judgement based on experience gained with similar projects; and
- Consultation with affected stakeholders in August and September 2022. It must be noted that not every individual in each community could be consulted. Consultations took place in Hout Bay, Steenberg's Cove, Lamberts Bay and Port Nolloth. Due to other commitments the meeting with the Guriqua leadership could not take place. The meeting in Hondeklip Bay got cancelled at the last minute by the stakeholders.

3.2 Assumptions and limitations

The following assumptions and limitations were relevant:

1. Not every individual in the community could be interviewed therefore only key people in the community were approached for discussion. Additional information was obtained using existing data.
2. The social environment constantly changes and adapts to change, and external factors outside the scope of the project can offset social changes, for example changes in local political leadership, droughts or economic conditions. It is therefore difficult to predict all impacts to a high level of accuracy, although

care has been taken to identify and address the most likely impacts in the most appropriate way for the current local context within the limitations.

3. Given that the survey will be conducted over a short period of time, the the impacts will be short term and from an outsiders perspective may appear as inconsequential. However, the outcomes of the survey will introduce new social impacts, and the potential of these impacts occuring is already causing fear and uncertainty amongst coastal communities. Communities view the survey as the beginning of potentially significant changes in their socio-economic environment.

4. Social impacts can be felt on an actual or perceptual level, and therefore it is not always straightforward to measure the impacts in a quantitative manner.

5. Social impacts commence when the project enters the public domain. Some of these impacts will occur irrespective of whether the project continues or not, and other impacts have already started. These impacts are difficult to mitigate and some would require immediate action to minimise the risk.

6. There are different groups with different interests in the community, and what one group may experience as a positive social impact, another group may experience as a negative impact. This duality will be pointed out in the impact assessment phase of the report.

7. Social impacts are not site-specific, but take place in the communities surrounding the proposed development.

8. Limited time was available for conducting the assessment.

3.3 Social Impact Assessment Model

The theoretical model used for this impact assessment was developed by Slootweg, Vanclay and Van Schooten and presented in the *International Handbook of Social Impact Assessment* (Vanclay & Becker, 2003). This model identifies pathways by which social impacts may result from proposed projects. The model differentiates between social change processes and social impacts, where the social change process is the

5108

pathway leading to the social impact. Detail of how the model works is not relevant to this study, but it is important to understand the key concepts, which will be explained in the following paragraphs.

Social change processes are set in motion by project activities or policies. A social change process is a discreet, observable, and describable process that changes the characteristics of a society, taking place regardless of the societal context (that is, independent of specific groups, religions etc.) These processes may, in certain circumstances and depending on the context, lead to the experience of social impacts (Vanclay, 2003). If managed properly, however, these changes may not create impacts. Whether impacts are caused will depend on the characteristics and history of the host community, and the extent of mitigation measures that are put in place (Vanclay, 2003). Social change processes can be measured objectively, independent of the local context. Examples of social change processes are an increase in the population, relocation, or the presence of temporary workers.

For the purpose of this report, the following social change process categories were considered:

- Demographic processes;
- Economic processes;
- Geographic processes;
- Institutional and legal processes;
- Emancipatory and empowerment processes;
- Socio-cultural processes; and
- Other relevant processes.

The *International Association for Impact Assessment* (2003) states that Social Impact Assessment includes the processes of analysing, monitoring, and managing the intended and unintended social consequences, both positive and negative, of planned interventions (policies, programs, plans, projects) and any social change processes

invoked by these interventions. Its primary purpose is to bring about a more sustainable and equitable biophysical and human environment.

A social impact is something that is experienced or felt by humans. It can be positive or negative. Social impacts can be experienced in a physical or perceptual sense. Therefore, two types of social impacts can be distinguished:

- **Objective social impacts** – i.e. impacts that can be quantified and verified by independent observers in the local context, such as changes in employment patterns, in standard of living or in health and safety.
- **Subjective social impacts** – i.e. impacts that occur "in the heads" or emotions of people, such as negative public attitudes, psychological stress or reduced quality of life.

It is important to include subjective social impacts, as these can have far-reaching consequences in the form of opposition to, and social mobilisation against the project (Du Preez & Perold, 2005).

For the purpose of this SIA, the following Social Impact Assessment categories were investigated:

- Health and social well-being;
- Quality of the living environment;
- Economic impacts and material well-being;
- Cultural impacts;
- Family and community impacts;
- Institutional, legal, political and equity impacts; and
- Gender impacts.

Relevant criteria for selecting significant social impacts included the following:

- Probability of the event occurring;
- Number of people that will be affected;

505

- Duration of the impact;
- Value of the benefits or costs to the impacted group;
- Extent to which identified social impacts are reversible or can be mitigated;
- Likelihood that an identified impact will lead to secondary or cumulative impacts;
- Relevance for present and future policy decisions;
- Uncertainty over possible effects; and
- Presence or absence of controversy over the issue.

The model was adapted to suit the South African context, and where processes and impacts were not relevant to the study, it was omitted. Each category has a number of sub-categories, which also have been investigated. The Equator Principles, International Finance Corporation Performance Standards and World Bank Environmental, Health and Safety guidelines were consulted in the writing of this report and the mitigation suggested adheres to these requirements.

3.4 Literature study

A literature search was undertaken to obtain secondary data for the baseline description of the socio-economic environment. The information in this report was acquired via statistical data obtained from Statistics South Africa, SIA literature (see References), previous studies conducted in the area, EIMS's public consultation process and information from reputable sources on the World Wide Web.

3.5 Research approach

Traditionally there are two approaches to SIA, a technical approach, and a participatory approach. A technical approach entails that a scientist remains a neutral observer of social phenomena. The role of the scientist is to identify indicators, obtain objective measures relevant to the situation and provide an expert assessment on how the system will change (Becker, Harris, Nielsen & McLaughlin, 2004). A participatory approach uses the knowledge and experiences of individuals most affected by the proposed changes as the basis for projecting impacts. In this case the

5028

role of the scientist is facilitator of knowledge sharing, interpretation, and reporting of impacts (Becker et al, 2004). A combination of these approaches was used for this study.

The findings presented in this report are based on primary and secondary (desk) research. A qualitative approach was followed for the primary research, while qualitative and quantitative data were used for the secondary research.

The layperson sometimes criticises qualitative research as "subjective" or "not really that scientific". For this reason, it is vital to understand the distinction between qualitative and quantitative research and their respective areas of application.

Qualitative research as a research strategy is usually characterised by the inference of general laws from particular instances, forms theory from various conceptual elements, and explains meaning (David & Sutton, 2004). It emphasises words rather than quantification in the collection and analysis of data. Data collection takes place by using methods such as unstructured or semi-structured interviews, focus groups, observations, etc. Data is not recorded in any standardised coding format but is usually reported according to themes. Qualitative data express information about feelings, values, and attitudes. This approach is used where insight and understanding of a situation is required (Malhotra, 1996). Participants are selected based on their exposure to the experience or situation under review. The aim of qualitative research is to understand, not to quantify and as such it is extremely suitable for assessing social impacts. A potential impact must be understood before it can be assessed appropriately.

Quantitative research as a research strategy usually makes inferences of particular instances by reference to general laws and principles and tends to emphasize what is external to or independent of the mind (objective) and incorporates a natural science model of the research process (David & Sutton, 2004). This makes it easier for a person with a natural or physical sciences background to relate to. This approach emphasises quantification in the collection and analysis of data. Data collection take place by using methods such as structured questionnaires and data is recorded in a numeric or some

other standardised coding format. Data is expressed in numerical format and statistical techniques are usually used to assist with data interpretation. This approach is used when information needs to be generalised to a specific population and participants are usually selected using probability sampling techniques (although non-probability methods can be used depending on the characteristics of the target population).

Although in theory the qualitative phase of this project could be followed by a quantitative phase, for a number of reasons it was not done. A quantitative phase would be more resource intensive in terms of labour, time and cost and the incremental precision obtained in terms of generalisability would not warrant the additional investment. Due to the strong emotional component relating to the perceived impacts, respondents may intentionally magnify the intensity of the impacts or indicate all impacts are equally severe in an attempt to bias the results in their favour, which will reduce the utility of quantitative results as part of the primary research process.

3.6 Ethical issues

The most basic principle of research is that participants should not be harmed by participation in the research project. It is important that research not only does no harm, but also potentially contributes to the wellbeing of others. At times this might place a researcher in a difficult position – what is beneficial to one group may not be beneficial to another (Bless, Higson-Smith & Kagee, 2006). Furthermore, an individual has the autonomy to decide whether to participate in research or not. No person should be forced, either overtly or covertly, to participate in research. Other important principles include justice (based on the assumption that all people are equals), fidelity (keeping promises or agreements, specifically between the researcher and the participant) and respect for participants' rights and dignity. In addition to these overarching ethical principles, important ethical principles that should be met are informed consent, confidentiality, anonymity, and discontinuance. This is in line with international as well as national research practice such as the World Association for Market, Social and Opinion Researchers (ESOMAR) and Southern African

Marketing Research Association (SAMRA) codes of conduct. The researcher has an ethical obligation to develop well-designed projects and execute them with care. Researchers are not allowed to change their data or observations and should report on technical shortcomings, failures, limits of the study, negative findings, and methodological constraints. The honest and accurate reporting of data is also an essential component of scientifically accurate and ethically legitimate research and conclusions should be supported by data.

4 Legislative and Policy Framework

Although there are no explicit acts referring directly to SIA, there are many acts and policies that require specific social outcomes that can be related to this project, and these are discussed in the section below.

4.1 The Constitution of the Republic of South Africa 1996

The current Constitution of the Republic of South Africa 1996 can be regarded as one of the most progressive constitutions in the world. Human rights are enshrined in the South African Constitution, which forms the basis of all the country's legislation. Chapter 2 consists of a Bill of Rights, which explicitly spells out the rights of every South African citizen. Human rights and dignity are fundamental to SIA and it recognises fundamental human rights and the prerogative to protect those rights as core values (Vanclay, 2003). The human rights relevant to the environmental management field that are safeguarded by the Constitution of the Republic of South Africa 1996 in the Bill of Rights, include:

- Right to a healthy environment;
- Right of access to land and to security of tenure; and
- Right to adequate housing and protection against evictions and demolitions.

The right to a protected biophysical environment, the promotion of social development and trans-generational equity is explicitly included in the Constitution of the Republic of South Africa 1996, which states:

"Everyone has the right -

1. To an environment that is not harmful to their health and wellbeing, and
2. To have the environment protected, for the benefit of present and future generations, through reasonable legislative and other measures that:
    1. *Prevent pollution*
    2. *Promote conservation, and*

3. *Secure ecologically sustainable development and use of natural resources while promoting justifiable economic and social development."*

When considering an environment that is not harmful to peoples' health and wellbeing, it is important to reflect on the interconnectedness of biophysical, economic, and social aspects. The impact of development on people, and the true cost of development, as well as the consideration of "who pays the price?" versus "who reaps the benefits?" cannot be ignored in a discussion about human rights and the environment.

The right to a generally satisfactory environment is increasingly seen as a human right in Africa (Du Plessis, 2011), and South Africa's environmental legislation supports this.

4.1.1 The National Environmental Management Act 107 of 1998

The National Environmental Management Act (NEMA) 107 of 1998 states that the State must respect, protect, promote and fulfil the social, economic and environmental rights of everyone and strive to meet the needs of previously disadvantaged communities. It states further that sustainable development requires the integration of social, economic and environmental factors in the planning, evaluation and implementation of decisions to ensure that development serves present and future generations.

Chapter 1 of NEMA contains a list of principles and states clearly that environmental management must place people and their needs at the forefront of its concern, and serve their physical, psychological, developmental, cultural and social interests (NEMA, 1998). It states further that negative impacts on the environment and on peoples' environmental rights must be anticipated and prevented, and if they cannot be prevented, they should be minimised and remedied. It elaborates further on the equity of impacts, and the fact that vulnerable communities should be protected from negative environmental impacts. It refers to the principle that everyone should have equal access to environmental resources, benefits and services to meet their basic

human needs (NEMA, 1998). Therefore there is a clear mandate for environmental and restorative justice in the act, something that must be considered in this project.

Another important aspect of NEMA is the principle of public participation. It states that people should be empowered to participate in the environmental governance processes, and that their capacity to do so should be developed if it does not exist. All decisions regarding the environment should take the needs, interest and values of the public into account, including traditional and ordinary knowledge (NEMA, 1998). There are also specific environmental management acts that fall under NEMA, such as the National Environmental Management, Air Quality Act 39 of 2004 (NEM: AQA), and the National Environmental Management, Waste Act 59 of 2008 (NEM: WA). These acts require similar public participation processes to NEMA and the principles of NEMA also apply to them (Department of Environmental Affairs & Development Planning [DEA&DP], Provincial Government of the Western Cape, 2010).

Chapter 6 of NEMA elaborates on the public participation requirements. This is supplemented by the EIA regulations published in GN 982 of 4 December 2014, which contained requirements for public participation (GN 982 in GG 38282 of 4 December 2014). It provides requirements for the public participation, the minimum legal requirements for public participation processes, the generic steps of a public participation process, requirements for planning a public participation process and a description of the roles and responsibilities of the various role players. A compulsory Public Participation Guideline that was published in 2012 (GN 807 of 10 October 2012) in terms of section J of NEMA (NEMA, 1998) complements these requirements. According to the guidelines, public participation can be seen as one of the most important aspects of the environmental authorisation process. Public participation is the only requirement of the environmental impact assessment process for which exemption cannot be given unless no rights are affected by an application. This stems from the requirement in NEMA that people have a right to be informed about potential decisions that may affect them and that they must be given an opportunity to influence those decisions.

The principles of the National Environmental Management Act 107 of 1998 declare further that community wellbeing and empowerment must be promoted through environmental education, the raising of environmental awareness, sharing of environmental knowledge and experience and any other appropriate means. It states that the social, environmental and economic impacts of activities, including disadvantages and benefits, must be considered, assessed and evaluated, and decisions taken must be appropriate given the assessment and evaluation. NEMA 107 of 1998 recognises that the environment is held in public trust for the people, and therefore the beneficial use of environmental resources must serve the peoples' interest and protect the environment as the peoples' common heritage.

NEMA takes a holistic view of the environment, and promotes the consideration of social, economic, and biophysical factors to obtain sustainable development and achieve effective management of the biophysical environment.

4.1.2 The Mineral and Petroleum Resources Development Act 28 of 2002

The Mineral and Petroleum Resources Development Act (MPRDA) 28 of 2002 is the only environmental act that explicitly requires a social development output, in addition to a public participation process, in the form of a Social and Labour Plan (SLP). In the preamble to the Act it recognises the need to promote local and rural development and the social upliftment of communities affected by resource development. In Section 2 it states that some of the objectives of the act are:

- To substantially and meaningfully expand opportunities for historically disadvantaged persons, including women, to enter the mineral and petroleum industries and to benefit from the exploitation of the nations' mineral and petroleum resources;
- To promote economic growth and mineral and petroleum resources development in the Republic;
- To promote employment and advance the social and economic welfare of all South Africans, and

- To ensure that holders of mining and production rights contribute towards the socio-economic development of the areas in which they are operating.

The MPRDA acknowledges that mineral and petroleum resources are the common heritage of all the people of South Africa and that the State is the custodian thereof for the benefit of all. It states that the Minister of Mineral Resources must ensure the sustainable development of South Africa's mineral and petroleum resources within a framework of national environmental policy, norms and standards while promoting economic and social development (MPRDA, 2002).

In Section 37 of the Mineral and Petroleum Resources Development Act 28 of 2002 it endorses the principles set out in Chapter 1 of the National Environmental Management Act 107 of 1998. In Section 39 of the MPRDA the act explicitly requires a social impact assessment as well as an environmental impact assessment when it states that applicants must:

"...investigate, assess and evaluate the impact of his or her proposed prospecting or mining operations on:

(i) The environment;

(ii) The socio-economic conditions of any person who might be directly affected by the prospecting or mining operation..."

Section 3, Chapter 2, Part I, of the regulations (Government Notice 527, 23 April 2004) published under the MPRDA refers to the public participation process, which must be followed according to the Act. It includes advertising and an invitation to comment on the process.

Sections 40 to 46, Chapter 2, Part II, of the regulations published under the MPRDA deal with the Social and Labour Plan (SLP) requirements (Government Notice 527, 23 April 2004). The Department of Mineral Resources provided guidelines for the development of the SLP (Department of Mineral Resources, 2010). The guidelines specify the objectives of the SLP as:

5128

- Promote economic growth and mineral and petroleum resources development in the Republic;
- Promoting employment and advancing the social and economic welfare of all South Africans;
- Ensuring that holders of mining or production rights contribute towards the socio-economic development of the areas in which they are operating as well as the areas from which the majority of the workforce is sourced, and
- To utilise and expand the existing skills base for the empowerment of Historically Disadvantaged South Africans and to serve the community (Department of Mineral Resources, 2010).

The crux of this section is that the SLP requires applicants for mining and production rights to develop and implement comprehensive Human Resources Development Programmes including Employment Equity Plans, Local Economic Development Programmes and processes to save jobs and manage downscaling and/or closure (MPRDA 28 of 2002). According to the regulations, the above programmes are aimed at promoting employment and advancement of the social and economic welfare of all South Africans whilst ensuring economic growth and socio-economic development. The management of downscaling and/or closure is aimed at minimising the impact of commodity cyclical volatility, economic turbulence and physical depletion of the mineral or production resources on individuals, regions, or local economies. All mines in South Africa are required to compile an SLP, and they must report compliance on a yearly basis (MPRDA, 2002). Compiling an SLP must be done in a participatory manner, and local economic development initiatives must be aligned with the municipal integrated development planning processes. An SLP is not a social impact management plan per se, although it does aim to manage some negative social impacts. The guideline is very clear about the fact that measures put in place for the mitigation of impacts cannot be seen as mine community development projects (Department of Mineral Resources, 2010).

4.1.3 The National Heritage Resources Act 25 of 1999

Although the National Heritage Resources Act (NHRA) 25 of 1999 is not an environmental act per se, it is relevant in the field of environmental management. The

5028

NHRA affirms that every generation has a moral responsibility to act as trustee of the national heritage for later generations and that the State is obliged to manage heritage resources in the interest of all South Africans. The general principles for heritage management in Chapter 5 of the Act state that in order to ensure that heritage resources are effectively managed, the skills and capacities of persons and communities involved in heritage resources management must be developed. The Act further elaborates on the fact that heritage resources form an important part of the history and beliefs of communities and must be managed in a way that acknowledges the right of affected communities to be consulted and to participate in their management.

The general principles (Chapter 5) state that the identification, assessment and management of the heritage resources of South Africa must:

- Take account of all relevant cultural values and indigenous knowledge systems;
- Take account of material or cultural heritage value and involve the least possible alteration or loss of it;
- Promote the use and enjoyment of and access to heritage resources, in a way consistent with their cultural significance and conservation needs;
- Contribute to social and economic development, and
- Safeguard the options of present and future generations.

The National Heritage Resources Act 25 of 1999 therefore protects the cultural rights and heritage of the people of South Africa. It does not require explicit public participation, or give any guidelines on how the public should participate. It does refer, like the National Environmental Management Act 107 of 1998 and the National Water Act 36 of 1998, to social and economic development. Public participation processes may be requested by the South African Heritage Resources Agency if it deems it necessary for a specific project.

4.1.4 Promotion of Administrative Justice Act 3 of 2000

The Bill of Rights in the Constitution of the Republic of South Africa 1996 states that everyone has the right to administrative action that is legally recognised, reasonable, and procedurally just. The Promotion of Administrative Justice Act (PAJA) 3 of 2000

JL28

gives effect to this right. The PAJA applies to all decisions of all State organisations exercising public power or performing a public function in terms of any legislation that negatively affects the rights of any person. The Act prescribes what procedures an organ of State must follow when it takes decisions. If an organ of State implements a decision that impacts on an individual or community without giving them an opportunity to comment, the final decision will be illegal and may be set aside. The Promotion of Administrative Justice Act 3 of 2000 also forces State organisations to explain and give reasons for the manner in which they have arrived at their decisions and, if social issues were involved, and how these issues were considered in the decision-making process.

The Promotion of Administrative Justice Act 3 of 2000 therefore protects the rights of communities and individuals to participate in decision-making processes, especially if these processes affect their daily lives.

4.1.5 Traditional and Khoi-San Leadership Act

The Traditional and Khoi-San Leadership Act 3 of 2019 aims:

- to provide for the recognition of traditional and Khoi-San communities, leadership positions and for the withdrawal of such recognition;
- to provide for the functions and roles of traditional and Khoi-San leaders;
- to provide for the recognition, establishment, functions, roles and administration of kingship or queenship councils, principal traditional councils, traditional councils, Khoi-San councils and traditional sub-councils, as well as the support to such councils;
- to provide for the establishment, composition and functioning of the National House of Traditional and Khoi-San Leaders;
- to provide for the establishment of provincial houses of traditional and Khoi-San leaders;
- to provide for the establishment and composition of local houses of traditional and Khoi-San leaders;
- to provide for the establishment and operation of the Commission on Khoi-San Matters;

- to provide for a code of conduct for members of the National House, provincial houses, local houses and all traditional and Khoi-San councils;
- to provide for regulatory powers of the Minister and Premiers;
- to provide for transitional arrangements;
- to amend certain Acts;
- to provide for the repeal of legislation; and
- to provide for matters connected therewith.

4.1.6 Protection, Promotion, Development and Management of Indigenous Knowledge Act 6 of 2019

The Protection, Promotion, Development and Management of Indigenous Knowledge Act 6 of 2019 intends:

- to provide for the protection, promotion, development and management of indigenous knowledge;
- to provide for the establishment and functions of the National Indigenous Knowledge Systems Office;
- to provide for the management of rights of indigenous knowledge communities;
- to provide for the establishment and functions of the Advisory Panel on indigenous knowledge;
- to provide for access and conditions of access to knowledge of indigenous communities;
- to provide for the recognition of prior learning;
- to provide for the facilitation and coordination of indigenous knowledge-based innovation; and
- to provide for matters incidental thereto.

4.1.7 Marine Living Resources Act 18 of 1998

The Marine Living Resources Act 18 of 1998 intends:

- to provide for the conservation of the marine ecosystem, the long-term sustainable utilisation of marine living resources and the orderly access to exploitation, utilisation and protection of certain marine living resources; and

- for these purposes to provide for the exercise of control over marine living resources in a fair and equitable manner to the benefit of all the citizens of South Africa; and
- to provide for matters connected therewith.

4.2 Additional governance tools

Legislation is not the only tool that authorities can use to achieve sustainable development and social development outcomes. There are several tools, policies and strategic planning instruments that can contribute to this.

4.2.1 Integrated Development Plans

For the purpose of this project, Integrated Development Plan (IDP) documents of the following municipalities need to be considered:

4.2.1.1 Namakwa District Municipality

In its IDP the Namakwa District Municipality states that its strategic objectives are:

- Monitoring and support local municipalities to deliver basic services which include water, sanitation, housing, electricity and waste management
- Support vulnerable groups in the district
- Improve administrative and financial viability and capability
- Promote and facilitate Local Economic Development (include tourism)
- Enhance good governance (include IGR) (IGR - intergovernmental relations)
- Promote and facilitate spatial transformation and sustainable urban development
- To render municipal health services
- To coordinate the disaster management and fire management services in the district
- Caring for the environment.

4.2.1.1.1 Richtersveld Local Municipality

The Richtersveld Local Municipality indicated in its IDP that its strategic goals/objectives are:

- For every household to have access to clean water, electricity, and sanitation

- To treat all their residents with pride and dignity
- To be an effective and efficient local government
- To be an effective instrument of change within its community
- To be a local government that is accountable with community driven development
- To be the gateway for local economic development and tourism in the north-western coast of the Northern Cape.

4.2.1.1.2 Nama Khoi Local Municipality

The key performance areas of the Nama-Khoi Local Municipality are:

- Basic services delivery
- Municipal financial viability and management
- Local economic development
- Municipal transformation and institutional development
- Good governance and community participation.

4.2.1.1.3 Kamiesberg Local Municipality

The Kamiesberg Local Municipality identified its key performance areas in its IDP as:

- Service delivery – to provide and maintain superior decentralised customer services (water, sanitation, roads, storm water, waste management and electricity)
- Local economic development
- Financial viability
- Municipal transformation
- Good governance.

4.2.1.2 West Coast District Municipality

The West Coast District Municipality stated in its IDP that its objectives are to:

- Care for the social well-being, safety and health of all our communities
- Promote regional economic growth and tourism
- Coordinate and promote the development of bulk and essential services and transport infrastructure

- Foster sound relationships with all stakeholders, especially local municipalities
- Maintain financial viability and good governance.

4.2.1.2.1 Matzikama Local Municipality

The Matzikama Local Municipality identified the following strategic objectives in its IDP:

- Provide municipal basic services to meet demands of growing population and development challenges
- Maintain sufficient revenue resources to enable the municipality to meet its constitutional obligations
- Coordinate, facilitate and stimulate sustainable economic development through strategy, policy and programme development
- Reduce poverty levels as measured by SAMPI
- Maintain sufficient organisation resources, enhance the involvement of the public in the development and decision making processes and provide ethical and professional services to support the needs of the communities
- Provide opportunities to officials and councillors for the development of professional and leadership skills and enhance employment equity in the organisation
- Develop and sustain our spatial, natural and built environment.

4.2.1.2.2 Cederberg Local Municipality

The Bergriver Local Municipality identified the following strategic goals:

- Strengthen financial sustainability and further enhancing good governance
- Sustainable service delivery
- Facilitate an enabling environment for economic growth to alleviate poverty
- Promote safe, healthy, educated and integrated communities
- A sustainable, inclusive and integrated living environment

4.2.1.2.3 Bergrivier Local Municipality

The Cederberg Local Municipality identified the following strategic objectives:

- Improve and sustain basic service delivery and infrastructure development
- Financial viability and economically sustainability

- Good governance, community development and public participation
- Facilitate, expand and nurture sustainable economic growth and eradicate poverty
- Enable a resilient, sustainable, quality and inclusive living environment and human settlements i.e. housing development and informal settlement upgrade
- To facilitate social cohesion, safe and healthy communities
- Development and transformation of the institution to provide a people-centred human resources and administrative services to citizens, staff and council.

4.2.1.2.4 Saldanha Bay Local Municipality

The Saldanha Bay Local Municipality identified the following strategic actions to create additional growth:

- **Retaining large existing exporting businesses**
- **Promote Aquaculture-, Fishing-, and Food processing sectors**
- Tourism growth
- **Attract new industrial investors by creating a more enabling environment**
- **Maximise the competitive advantages for ports**
- **Support local SME to access more opportunities**
- **Availability of credible vocational skills development and tertiary education**

4.2.1.2.5 Swartland Local Municipality

The strategic goals of the Swartland Local Municipality are:

- Improved quality of life for citizens
- Inclusive economic growth
- Quality and sustainable living environment
- Caring, competent and responsive institutions, organisations, and business
- Sufficient, affordable and well-run services.

4.2.1.3 City of Cape Town Metropolitan Municipality

The City of Cape Town has sixteen objectives linked to its priorities and foundations:

- Economic growth

- Increased jobs and investment in the Cape Town economy

- Basic services
  - Improved access to quality and reliable basic services
  - End load-shedding in Cape Town over time
  - Well-managed and modernised infrastructure to support economic growth
- Safety
  - Effective law enforcement to make communities safer
  - Strengthen partnerships for safer communities
- Housing
  - Increased supply of affordable, well-located homes
  - Safer, better-quality homes in informal settlements and backyards over time
- Public space, environment and amenities
  - Healthy and sustainable environment
  - Clean and healthy waterways and beaches
  - Quality and safe parks and recreational facilities supported by community partnerships
- Transport
  - A sustainable transport system that is integrated, efficient and provides safe and affordable options for all
  - Safe and quality roads for pedestrians, cyclists and vehicles
- A resilient city
- A more spatial integrate and inclusive city
- A capable and collaborative city government.

4.2.2 Provincial Growth and Development Strategies

The Provincial Growth and Development Strategies of the Northern Cape and Western Cape Provinces need to be considered.

4.2.2.1 Northern Cape Strategic Plan 2020-2035

The four drivers of the Northern Cape Provincial Growth and Development Plan:

- Economic transformation, growth and development

  To ensure economic growth and development that will lead to job creation and radical economic transformation for the people of the Northern Cape Province, ten economic drivers or development paths have been identified:

  - Agriculture and agro-processing
  - Mining and mineral beneficiation
  - Tourism market development
  - Rural development and land reform
  - Development of energy sector
  - Manufacturing and trade
  - Competitive infrastructure development
  - Employment and skills development
  - Innovation and knowledge economy
  - Marine economy

- Social transformation and human welfare

  To sustainably address the social injustices and inequalities in the province, social transformation must be accelerated and deepened towards human development and welfare. The following six drivers have been identified:

  - Quality basic education
  - Quality health care
  - Social cohesion and community participation
  - Social protection and safety
  - Sustainable human developments
  - Employment and skills development

- Environmental sustainability and resilience

  The Northern Cape Province has an abundance of natural resources and environmental assets. While these present a wide range of economic opportunities, a concerted effort must be made to ensure that these are protected and enhance to support the developmental objectives of the

province. As the province is an arid region, it must be ensured that enough is done to mitigate the real threat of climate change.

- Effective, efficient, and accountable governance

  A capable and accountable government based on strong inter-governmental cooperation and participatory governance with civil society will be better positioned and capable to perform seamless services based on the needs of those on whose behalf they govern. Three drivers have been identified to facilitate effective, efficient, and accountable governance:

  - Developmental and democratic state
  - Effective local government
  - International relations

4.2.2.2 Western Cape Provincial Strategic Plan 2019-2024

Vision has five strategic priorities with the following problem areas and focus areas:

- Safe and cohesive communities – a place where residents and visitors feel safe
  - Problem areas
    - Violence and violent crime
    - Police capacity and public trust
    - Cohesive communities
  - Focus areas
    - Enhanced capacity and effectiveness of policing and law enforcement
    - Strengthened youth-at-risk referral pathways and child- and family centred initiatives to reduce violence
    - Increased social cohesion and safety in public places
- Growth and jobs – an enabling environment for the private sector and markets to drive growth and create jobs
  - Problem areas
    - Weak economic performance persists
    - Unemployment persists
    - Climate change impacts and resource pressures

- Focus areas
  - Increasing investment
  - Building and maintaining infrastructure
  - Growing the economy through export growth
  - Creating opportunities for job creation through skills development
  - Creating an enabling environment for economic growth through resource resilience

- Empowering people -residents have opportunities to shape their lives and the lives of others, to ensure a meaningful and dignified live
  - Problem areas
    - Children and families live in unhealthy, violent, neglectful and dysfunctional environments that impede proper development
    - Children have unequal access to quality holistic education and extended learning opportunities, which limits post-schooling success
    - Youth engage in unhealthy and risky behaviours, have few educational and economic opportunities, and become disconnected from productive society
    - Health outcomes are uneven between rich and poor and, despite successes in areas like HIV treatment and sexual and reproductive health, there is an inability to fulfil the growing demand for health services
  - Focus areas
    - Children and families
    - Education and learning
    - Youth and skills
    - Health and wellness

- Mobility and spatial transformation – residents live in well-connected, vibrant, and sustainable communities and move around efficiently on safe, affordable, low-carbon public transport
  - Problem areas
    - Poor communities far from social and economic opportunities

- Inadequate public transport
- Infrastructure backlogs and challenges

- Focus areas
  - Create better linkages between places through safe, efficient, and affordable public transport
  - Inclusive places of opportunities
  - More opportunities for people to live in better locations
  - Improving the places where people live

- Innovation and culture – government services are delivered to the people in an accessible, innovative, and citizen-centric way
  - Problem areas
    - Inward-focused organisational culture
    - Western Cape Government innovation exists, but is not fully embedded
    - Limited integration across the spheres of government and with external partners
    - Good governance is primarily driven by compliance processes
    - Talent and staff development is not responsive to the changing world of work
  - Focus areas
    - Citizen-centric culture
    - Innovation for impact
    - Integrated service delivery
    - Governance transformation
    - Talent and staff development

4.2.3 National Development Plan

On 11 November 2011 the National Planning Commission released the National Development Plan: Vision for 2030 (NPC, 2012) for South Africa and it was adopted as government policy in August 2012. The National Development Plan (NDP) was undertaken to envision what South Africa should look like in 2030 and what action

steps should be taken to achieve this (RSA, 2013). The aim of the NDP is to eliminate poverty and reduce inequality by 2030. The report identifies nine central challenges to development in South Africa:

1. Too few people work.
2. The standard of education for most black learners is of poor quality.
3. Infrastructure is poorly located, under-maintained and insufficient to foster higher growth.
4. Spatial patterns exclude the poor from the fruits of development.
5. The economy is overly and unsustainably resource intensive.
6. A widespread disease burden is compounded by a failing public health system.
7. Public services are uneven and often of poor quality.
8. Corruption is widespread.
9. South Africa remains a divided society (NPC, 2012).

The plan focuses on creating an enabling environment for development and wants to shift from a paradigm of entitlement to a paradigm of development that promotes the development of capabilities, the creation of opportunities and the involvement of all citizens (NPC, 2012). The National Development Plan (NPC, 2012) wants to achieve the following:

1. An economy that will create more jobs.
2. Improving infrastructure.
3. Transition to a low-carbon economy.
4. An inclusive and integrated rural economy.
5. Reversing the spatial effects of apartheid.

JC28

6. Improving the quality of education, training, and innovation.
7. Quality healthcare for all.
8. Social protection.
9. Building safer communities.
10. Reforming the public service.
11. Fighting corruption.
12. Transforming society and uniting the country.

Each of the points above is a chapter in the plan and contains a range of targets and proposals. Some are general statements of policy intent, while others are specific policy proposals, actions or processes that should take place (NPC, 2012).

4.2.4 Sustainable Development Goals

All 189 Members States of the United Nations, including South Africa, adopted the United Nations Millennium Declaration in September 2000 (UN, 2000). The commitments made by the Millennium Declaration are known as the Millennium Development Goals (MDGs), and 2015 was targeted as the year to achieve these goals. The United Nations Open Working Group of the General Assembly identified seventeen sustainable development goals, built on the foundation of the MDGs as the next global development target (UN, 2014). The sustainable development goals include aspects such as ending poverty, addressing food security, promoting health, wellbeing and education, gender equality, water and sanitation, economic growth and employment creation, sustainable infrastructure, reducing inequality, creating sustainable cities and human settlements, and addressing challenges in the physical environment such as climate change and environmental resources (UN, 2014). These aspects are included in the NPD, and it can therefore be assumed that South Africa's development path is aligned with the international development agenda.

EOS

4.3 National and international standards

National and international industry standards aimed at sustainable development and social justice specifically have become abundant in the last decade. Many industries use these standards as indicators for best practice. The discussion below highlights only a few of these standards.

4.3.1 ISO 26000:2010/SANS 26000:2010

Performance standards have long been a voluntary tool used by industry to achieve certain outcomes. The first standard on social responsibility, ISO 26000 was published on 1 November 2010 (ISO, 2010). It was developed using a multi-stakeholder approach involving experts from more than 90 countries and 40 international or broadly based regional organisations involved in different aspects of social responsibility (ISO, 2010).

The South African Bureau of Standards (SABS), a statutory body that is mandated to develop, promote and maintain South African National Standards (SABS, [sa]) adopted the ISO 26000 Standard as a South African National Standard (SANS) 26000:2010.

Social responsibility is defined in the standard as the responsibility of an organisation for the impacts of its decisions and activities on society and the environment, through transparent and ethical behaviour that contributes to sustainable development, including health and welfare of society; takes into account the expectations of the stakeholders; complies with applicable law and is consistent with international behaviour norms, and is integrated throughout the organisation and practiced in its relationships (ISO, 2010).

The document identifies seven principles for social responsibility and seven core subjects that should be addressed by organisations. The seven principles for social responsibility are accountability, transparency, ethical behaviour, respect for stakeholder interests, respect for the rule of law, respect for international norms of behaviour and respect for human rights (ISO, 2010). The core subjects that should be addressed include organisational governance, human rights, labour practices, environment, fair operating practices, consumer issues and community involvement

FLOS

and development (ISO, 2010). Economic aspects, health and safety and the value chain are dealt with throughout the seven core subjects, and gender issues are considered.

ISO 26000 is a good introduction to what social responsibility is and what measures should be taken to move towards being a more socially responsible company. It deals with equity issues and can encourage social development initiatives by companies through activities such as social investment projects, employment creation, skills development and income creation. Any company operating in area where people are affected by their activities has a social responsibility towards the affected community, and as such it would be in the interest of Searcher to address the core subjects as suggested by ISO 26000:2010.

4.3.2 International Social Performance Standards/Initiatives

There is a profusion of global initiatives aiming at assisting companies to make their operations more sustainable. Human rights, environmental protection and social justice are gaining support from industry. The social agenda forms an important part of this trend. Only a few relevant initiatives will be mentioned in this section.

The Global Reporting Initiative (GRI) is a leading organisation in the sustainability field that promotes sustainability reporting as a way for companies to become more sustainable and contribute to sustainable development. A company publishes a sustainability report to report the economic, social and environmental impacts of its everyday activities, present its values and governance model and explain the link between its strategy and its commitment to sustainable development (GRI, [sa]). The GRI have strategic partnerships with the United Nations Environment Programme, the United Nations Global Compact, the Organisation for Economic Co-operation and Development and the International Organisation for Standardisation, amongst others (GRI, [sa]). The social category relates to the impact of the company on the social systems in which it operates. The social category consists of four subcategories namely labour practices and decent work; human rights; society; and product responsibility. Each of the categories is unpacked by using a number of aspects that should be considered (GRI, [sa]). GRI Focal Points are national offices that drive the initiatives in

JC08

particular countries and regions. On 26 February 2013 the GRI Focal Point South Africa was launched. South Africa is one of the countries with the largest number of GRI reporters in the world. The GRI Focal Point South Africa aims to work with multi-national companies to expand and share best practices across the continent (GRI, [sa]).

Many of the multi-lateral funding agencies such as the World Bank have social standards that they must uphold. The most frequently used in the EIA industry is the International Finance Corporation's (IFC) principles (IFC, 2012). The IFC is a member of the World Bank group, and as a part of their sustainability framework they created performance standards on environmental and social sustainability (IFC, 2012). The standards relevant to the social environment are the following:

1. Environmental and Social Standard 1. Assessment and Management of Environmental and Social Risks and Impacts
2. Environmental and Social Standard 2: Labour and Working Conditions
3. Environmental and Social Standard 4: Community Health and Safety
4. Environmental and Social Standard 5 Land Acquisition, Restrictions on Land Use and Involuntary Resettlement
5. Environmental and Social Standard 8: Cultural Heritage
6. Environmental and Social Standard 10. Stakeholder Engagement and Information Disclosure (World Bank, 2016)

Issues such as gender, climate change, water and human rights are addressed across the standards. A guidance note accompanies each standard (IFC, 2012:4). Environmental and social risks and impacts must be managed by using an Environmental and Social Management System. The standard applies to all the activities funded by the IFC for the duration of the loan period. A number of private banks adopted most of the IFC standards in an initiative known as the Equator Principles (Esteves, Franks & Vanclay, 2012).

5C08

4.3.3 International Principles for SIA

The practice of SIA is guided by a set of *International Principles* that defines the core values, fundamental principles for development and principles specific to SIA practice (Vanclay, 2003). When the *International Principles* are considered, it is clear that SIA aspires to more than just assessing the impact of development on people and includes sustainable outcomes. The following specific principles refer to these sustainable outcomes (Vanclay, 2003):

1. Development projects should be broadly acceptable to the members of those communities likely to benefit from, or be affected by, the planned intervention.
2. The primary focus of all developments should be positive outcomes, such as capacity building, empowerment, and the realisation of human and social capital.
3. The term "environment" should be defined broadly to include social and human dimensions, and in such inclusion, care must be taken to ensure that adequate attention is given to the realm of the social.
4. Equity considerations should be a fundamental element of impact assessment and of development planning.
5. There should be a focus on socially sustainable development, with the SIA contributing to the determination of best development alternative(s) – SIA (and EIA) has more to offer than just being an arbiter between economic benefit and social cost.
6. In all planned interventions and their assessments, avenues should be developed to build the social and human capital of local communities and to strengthen democratic processes.
7. Local knowledge, experience and acknowledgement of different cultural values should be incorporated in any assessment.
8. Development processes that infringe the human rights of any section of society should not be accepted.

0603

In addition to the *International Principles*, the international SIA community produced a document titled: *Social Impact Assessment: Guidance for assessing and managing the social impacts of projects* (Vanclay, Esteves, Aucamp & Franks, 2015) in April 2015. The purpose of this document is to provide advice to various stakeholders (including proponents) about good practice SIA and social impact management (Vanclay et al., 2015). This document aspires to provide a much-needed benchmark for SIA practice across the globe.

5 Receiving environment

According to the National Environmental Management Act (NEMA, 1998) environment refers to the surroundings in which humans exist. When viewing the environment from a socio-economic perspective the question can be asked what exactly the social environment is. Different definitions for social environment exist, but a clear and comprehensive definition that is widely accepted remains elusive. Barnett & Casper (2001) offers the following definition of human social environment:

> *"Human social environments encompass the immediate physical surroundings, social relationships, and cultural milieus within which defined groups of people function and interact. Components of the social environment include built infrastructure; industrial and occupational structure; labour markets; social and economic processes; wealth; social, human, and health services; power relations; government; race relations; social inequality; cultural practices; the arts; religious institutions and practices; and beliefs about place and community. The social environment subsumes many aspects of the physical environment, given that contemporary landscapes, water resources, and other natural resources have been at least partially configured by human social processes. Embedded within contemporary social environments are historical social and power relations that have become institutionalized over time. Social environments can be experienced at multiple scales, often simultaneously, including households, kin networks, neighbourhoods, towns and cities, and regions. Social environments are dynamic and change over time as the result of both internal and external forces. There are relationships of dependency among the social environments of different local areas, because these areas are connected through larger regional, national, and international social and economic processes and power relations."*

Environment-behaviour relationships are interrelationships (Bell, Fisher, Baum & Greene, 1996). The environment influences and constrains the behaviour of people, but behaviour also leads to changes in the environment. The impacts of a project on

people can only be truly understood if their environmental context is understood. The baseline description of the social environment will include a description of the area within a provincial, district and local context that will focus on the identity and history of the area as well as a description of the population of the area based on a number of demographic, social and economic variables.

5.1 Description of the area

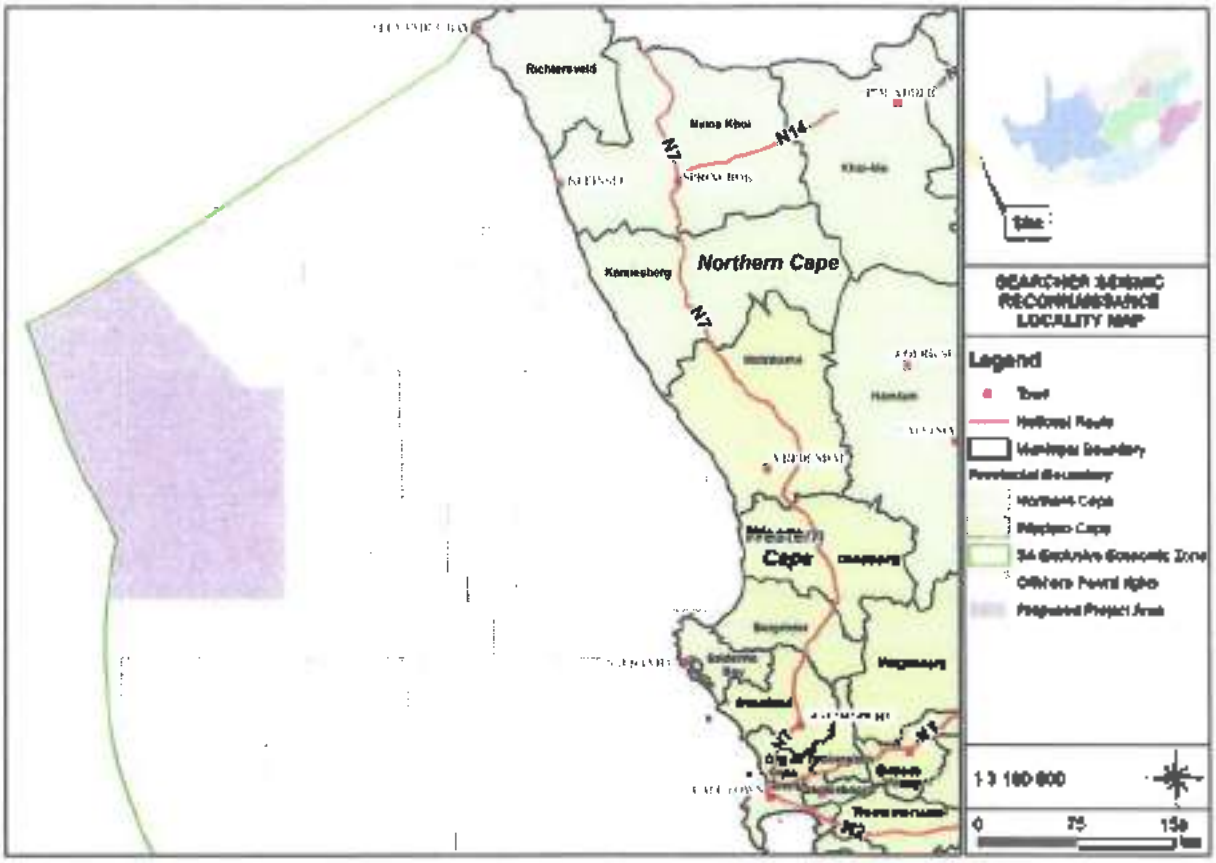
The proposed project area for the Searcher Seismic Reconnaissance project is located on the edge of the South African exclusive economic zone in the Atlantic Ocean. The people potentially affected by the proposed project are those living in the areas adjacent to the ocean whose activities could potentially be affected. The following areas are included in the baseline description of the social environment:

- Northern Cape Province
  - Namakwa District Municipality
    - Richtersveld Local Municipality (Wards 2, 3, 4)
    - Nama Khoi Local Municipality (Ward 8)
    - Kamiesberg Local Municipality (Wards 1, 2)
- Western Cape Province
  - West Coast District Municipality
    - Matzikama Local Municipality (Wards 2, 5, 8)
    - Cederberg Local Municipality (Ward 5)
    - Bergrivier Local Municipality (Wards 6, 7)
    - Saldanha Bay Local Municipality (Wards 1, 3, 5, 6, 11, 12, 14)
    - Swartland Local Municipality (Ward 5)
  - City of Cape Town Metropolitan Municipality (Wards 4, 23, 29, 32, 54, 55, 74, 107, 113, 115)

Figure 2 shows the location of the proposed project area in relation to these municipal areas.

JVB

Figure 2: Location of the proposed project area.



5.1.1 Northern Cape Province

The Northern Cape Province is South Africa's largest province. It takes up almost a third of the country and covers an area of 372 889 km² (www.municipalities.co.za). It is bordered by the provinces of North West, Free State, Eastern Cape and Western Cape as well as the countries of Namibia and Botswana and the Atlantic Ocean. It consists of the Frances Baard, John Taolo Gaetsewe, Namakwa, Pixley Ka Seme and ZF Mgcawu District Municipalities.

The capital of the province is Kimberley and other towns in the province include Springbok, Kuruman, De Aar, Sutherland, Alexander Bay, Port Nolloth, Kathu, Okiep, Springbok, Aggeneys, Upington, Kakamas, Keimoes and Warrenton.

The economy of the province relies mainly on mining and agriculture. Commodities being mined include iron ore, copper, asbestos, manganese, fluorspar, semi-precious stones, and marble. Alluvial diamonds are being extracted from the beaches and sea

5628

in the area around Alexander Bay and Port Nolloth. Agricultural products include sheep, wheat, fruit, grapes, wheat, peanuts, maize, and cotton. The province is known for its dried fruit, wine, and karakul pelt.

The spring-flowers in Namakwaland is a popular tourist attraction. The province also houses the southern hemisphere's largest astronomical observatory at Sutherland.

5.1.1.1 *Namakwa District Municipality*

The Namakwa District Municipality is the largest district municipality in the province and covers an area of 126 836 km² (www.municipalities.co.za). It is bordered by the ZF Mgcawu Local Municipality, the Cape Winelands, West Coast, Pixley Ka Seme and Central Karoo District Municipalities, the country of Namibia and the Atlantic Ocean. It is the largest district in the province, making up almost a third of the province.

The district consists of six local municipalities, namely the Hantam, Kamiesberg, Karoo Hoogland, Khai-Ma, Nama Khoi, and Richtersveld Local municipalities. The capital of the province is Springbok and other towns include Aggeneys, Alexander Bay, Brandvlei, Bulletrap, Calvinia, Carolusberg, Concordia, Eksteensfontein, Fraserburg, Garies, Hondeklip Bay, Kamieskroon, Kleinzee, Koingnaas, Komaggas, Kuboes, Leliefontein/Kamiesberg, Loeriesfontein, Middelpos, Nababeep, Nieuwoudtville, O'Kiep, Onderste Doorns, Pella, Pofadder, Port Nolloth, Richtersveld, Sanddrift, Springbok, Steinkopf, Sutherland, and Williston.

The main economic sectors are tourism and agriculture.

5.1.1.1.1 Richtersveld Local Municipality

The Richtersveld municipality is the smallest municipality in the district and covers an area of 9 608 km² (www.municipalities.co.za). The municipality borders the Atlantic Ocean and the main towns are Alexander Bay, Eksteensfontein, Kuboes, Port Nolloth, Richtersveld and Sanddrift. The main economic sectors are mining, agriculture, fishing and tourism.

5CJS

5.1.1.1.2 Nama Khoi Local Municipality

The Nama Khoi Local Municipality covers an area of 17 990 km² (www.municipalities.co.za). It is home to Nama, Khoe and San people who have occupied the area for hundreds of years. The municipality borders the Atlantic Ocean, and the main towns are Bulletrap, Carolusberg, Concordia, Kleinzee, Komaggas, Nababeep, O'Kiep, Springbok, Steinkopf. The main economic activities are mining and tourism, but there are also some government departments.

5.1.1.1.3 Kamiesberg Local Municipality

The Kamiesberg Local Municipality covers an area of 14 208 km² (www.municipalities.co.za). The municipality borders the Atlantic Ocean and the main towns are Garies, Hondeklip Bay, Kamieskroon, Koingnaas, and Leliefontein/Kamiesberg.

5.1.2 Western Cape Province

The Western Cape Province is located on the southern tip of Africa between the Atlantic and Indian Oceans and is bordered by the Northern Cape and Eastern Cape Provinces. It covers an area of 129 462 km² (www.municipalities.co.za). The province is divided into one metropolitan municipality and five district municipalities. The capital of the province is the city of Cape Town and other major cities and towns include George, Knysna, Paarl, Swellendam, Oudtshoorn, Stellenbosch, Worcester, Mossel Bay and Strand.

The province has a well-established industrial and business base. Main economic activities include finance, real estate, ICT, retail, and tourism. Fishing is the most important industry along the west coast and sheep farming in the Karoo. In terms of agriculture main produce include grapes, fruit, vegetables, and wheat. A number of vineyards are located in the Western Cape Province.

5.1.2.1 West Coast District Municipality

The West Coast District Municipality covers an area of 31 118 km² (www.municipalities.co.za) and is bordered by the Namakwa and Cape Winelands District Municipalities, the City of Cape Town, and the Atlantic Ocean. The municipality

consists of five local municipalities, namely the Swartland, Bergrivier, Matzikama, Cederberg and Saldanha Bay Local Municipalities.

The capital of the district is Moorreesburg and other main towns include Abbotsdale, Aurora, Bitterfontein, Chatsworth, Citrusdal, Clanwilliam, Darling, Doring Bay, Ebenhaezer, Eendekuil, Elands Bay, Graafwater, Grotto Bay, Hopefield, Jacobs Bay, Kalbaskraal, Klawer, Kliprand, Koekenaa, Koringberg, Lamberts Bay, Langebaan, Leipoldtville, Lutzville, Malmesbury, Moisvlei, Moorreesburg, Nuwerus, Paternoster, Piketberg, Porterville, Putsekloof, Redelinghuys, Riebeeck Kasteel, Riebeeck West, Rietpoort, Riverlands, Saldanha, St Helena Bay, Stofkraal, Strandfontein, Vanrhynsdorp, Velddrif, Vredenburg, Vredendal, Wupperthal, and Yzerfontein.

5.1.2.1.1 Matzikama Local Municipality

The Matzikama Local Municipality borders the Northern Cape Province and the Atlantic Ocean. It is the largest of the five municipalities in the district, making up almost half of the district. It covers an area of 12 981 km² (www.municipalities.co.za). There are 18 towns and villages in the municipal area with most of the population being concentrated along the Olifants River and its canal system. The main towns and villages include Bitterfontein, Doring Bay, Ebenhaezer, Klawer, Kliprand, Koekenaa, Lutzville, Moisvlei, Nuwerus, Putsekloof, Rietpoort, Stofkraal, Strandfontein, Vanrhynsdorp,aand Vredendal.

5.1.2.1.2 Cederberg Local Municipality

The Cederberg Local Municipality covers an area of 8 007 km² (www.municipalities.co.za). It is bordered by the Atlantic Ocean and the Cederberg Mountains and is located on the Cape-Namibia corridor. The main towns in the area include Citrusdal, Clanwilliam, Elands Bay, Graafwater, Lamberts Bay, Leipoldtville, and Wupperthal.

5.1.2.1.3 Bergrivier Local Municipality

The Bergrivier Local Municipality covers an area of 4 407 km² (www.municipalities.co.za). The main towns in the area include Aurora, Eendekuil, Piketberg, Porterville, Redelinghuys, and Velddrif.

5.1.2.1.4 Saldanha Bay Local Municipality

The Saldanha Bay Local Municipality is the smallest of the five municipalities in the district and covers an area of 2 015 km² (www.municipalities.co.za). The main towns in the area are Hopefield, Jacobs Bay, Langebaan, Paternoster, Saldanha, St Helena Bay, Vredenburg.

5.1.2.1.5 Swartland Local Municipality

The Swartland Local Municipality covers an area of 3 708 km² (www.municipalities.co.za). It is home to the town of Malmesbury that fulfils an important niche in the region due to its high development potential that can be attributed to factors like its relative accessibility along the N7 road/rail corridor; proximity to Cape Town; a diversified economic base that not only accommodates agriculture, but also well-developed industrial and commercial sectors; and supportive infrastructure. A number of people moved here and commute to jobs in Cape Town because of the high property rates in the Cape Town Metropolitan area and the tranquil environment that it offers.

Main towns in the area include Abbotsdale, Chatsworth, Darling, Grotto Bay, Kalbaskraal, Koringberg, Malmesbury, Moorreesburg, Riebeeck Kasteel, Riebeeck West, Riverlands, and Yzerfontein.

5.1.2.2 City of Cape Town Metropolitan Municipality

The City of Cape Town Metropolitan Municipality is situated in the southern peninsula of the Western Cape Province and covers an area of 2 441 km² (www.municipality.co.za). It is South Africa's second largest economic centre and the second most populous city after Johannesburg. It is the provincial capital as well as the legislative capital of South Africa. The city is known for its harbour, floral kingdom and well-known landmarks like Table Mountain and Cape Point.

Main towns and cities in the area include Athlone, Atlantis, Belhar, Bellville, Blackheath, Bloubeg, Blue Downs, Brackenfell, Cape Point, Cape Town, Delft, Durbanville, Elsies Rivier, Fish Hoek, Goodwood, Gordon's Bay, Grassy Park, Gugulatu, Hout Bay, Khayelitsha, Kommetjie, Kraaifontein, Kuils River, Lange, Macassar,

FW9

Matroosfontein, Melkbosstrand, Milnerton, Mitchells Plain, Muizenberg, Noordhoek, Nyanga, Parow, Philadelphia, Philippi, Robben Island, Scarborough, Simon's Town, Sir Lowry's Pass, Somerset West, Southern Suburbs, Strand, and Table View.

5.2 Description of the population

The baseline description of the population will take place on three levels, namely provincial, district and local. Impacts can only truly be comprehended by understanding the differences and similarities between the different levels. The baseline description will focus on the municipal areas along the west coast that are most likely to be affected by the proposed project. Where possible, the data will be reviewed on a ward level. The data used for the socio-economic description was sourced from Census 2011. Census 2011 was a *de facto* census (a census in which people are enumerated according to where they stay on census night) where the reference night was 9-10 October 2011. The results should be viewed as indicative of the population characteristics in the area and should not be interpreted as absolute.

The following points regarding Census 2011 must be kept in mind (www.statssa.co.za):

- Comparisons of the results of labour market indicators in the post-apartheid population censuses over time have been a cause for concern. Improvements to key questions over the years mean that the labour market outcomes based on the post-apartheid censuses must be analysed with caution. The differences in the results over the years may be partly attributable to improvements in the questionnaire since 1996 rather than to actual developments in the labour market. The numbers published for the 1996, 2001, and 2011 censuses are therefore not comparable over time and are different from those published by Statistics South Africa in the surveys designed specifically for capturing official labour market results.

- For purposes of comparison over the period 1996–2011, certain categories of answers to questions in the censuses of 1996, 2001 and 2011, have either been merged or separated.

- The tenure status question for 1996 has been dropped since the question asked was totally unrelated to that asked thereafter. Comparisons for 2001 and 2011 do however remain.

- All household variables are controlled for housing units only and hence exclude all collective living arrangements as well as transient populations.

- When making comparisons of any indicator it must be considered that the time period between the first two censuses is five years and that between the second and third census is ten years. Although Census captures information at one given point in time, the period available for an indicator to change is different.

5.2.1 Population and household sizes

According to the Community Survey 2016, the population of South Africa is approximately 55,7 million and has shown an increase of about 7.5% since 2011. The household density for the country is estimated on approximately 3.29 people per household, indicating an average household size of 3-4 people (leaning towards 3) for most households, which is down from the 2011 average household size of 3.58 people per household. Smaller household sizes are in general associated with higher levels of urbanisation.

The greatest increase in population since 2011 has been in the Swartland and Saldanha Bay Local Municipalities (Table 1) and the increases were well above the national average. The Richtersveld Local Municipality where Port Nolloth is located is the only one of the coastal municipalities in the Northern Cape that showed an increase in population. The Kamiesberg Local Municipality where Hondeklip Bay is located, saw the greatest decrease in population between 2011 and 2016. Population density refers to the number of people per square kilometre and the population density on a national level has increased from 42.45 people per km^2 in 2011 to 45.63 people per km^2 in 2016. The City of Cape Town had the highest population density in 2016, and the Kamiesberg Local Municipality the lowest.

5429

Figure 3 gives a comparison of the population density. The municipalities in the rural areas in the Northern Cape are the least densely populated, while the metropolitan areas in Cape Town have the highest population density.

1860

Figure 3: Population density (source: Community Survey 2016)

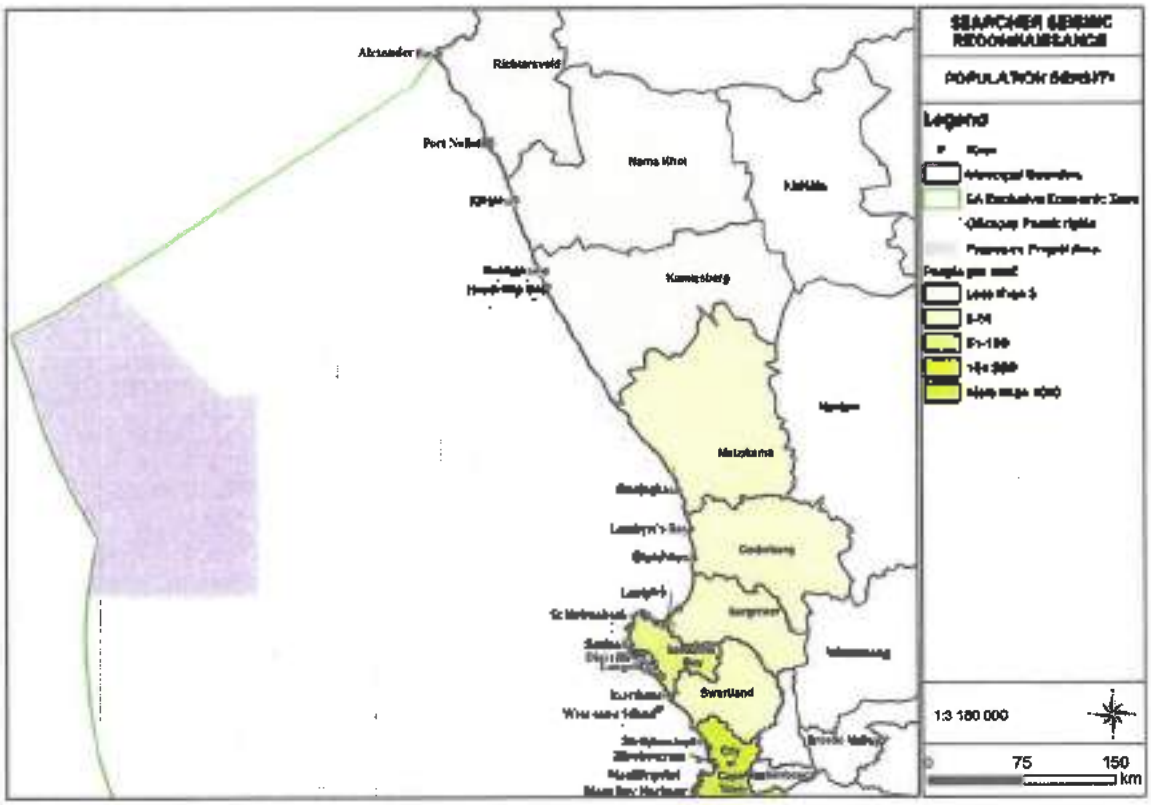


Figure 4 shows the number of people per ward. The wards in the rural areas tend to have less people spread over a greater area, while in the urban areas there are more people in a much smaller area.

Table 1: Population density and growth estimates (sources: Census 2011, Community Survey 2016)

Area	Size in km²	Population 2011	Population 2016	Population density 2011	Population density 2016	Growth in population (%)
Northern Cape	372,889	1,145,861	1,193,780	3.07	3.20	4.18
Namakwa DM	*126,836*	*115,842*	*115,488*	*0.91*	*0.91*	*-0.31*

City of Cape Town Metropolitan	*2,441*	*3,740,026*	*4,004,793*	*1,532.17*	*1,640.64*	*7.08*

5608

Figure 3: Population density (source: Community Survey 2016)

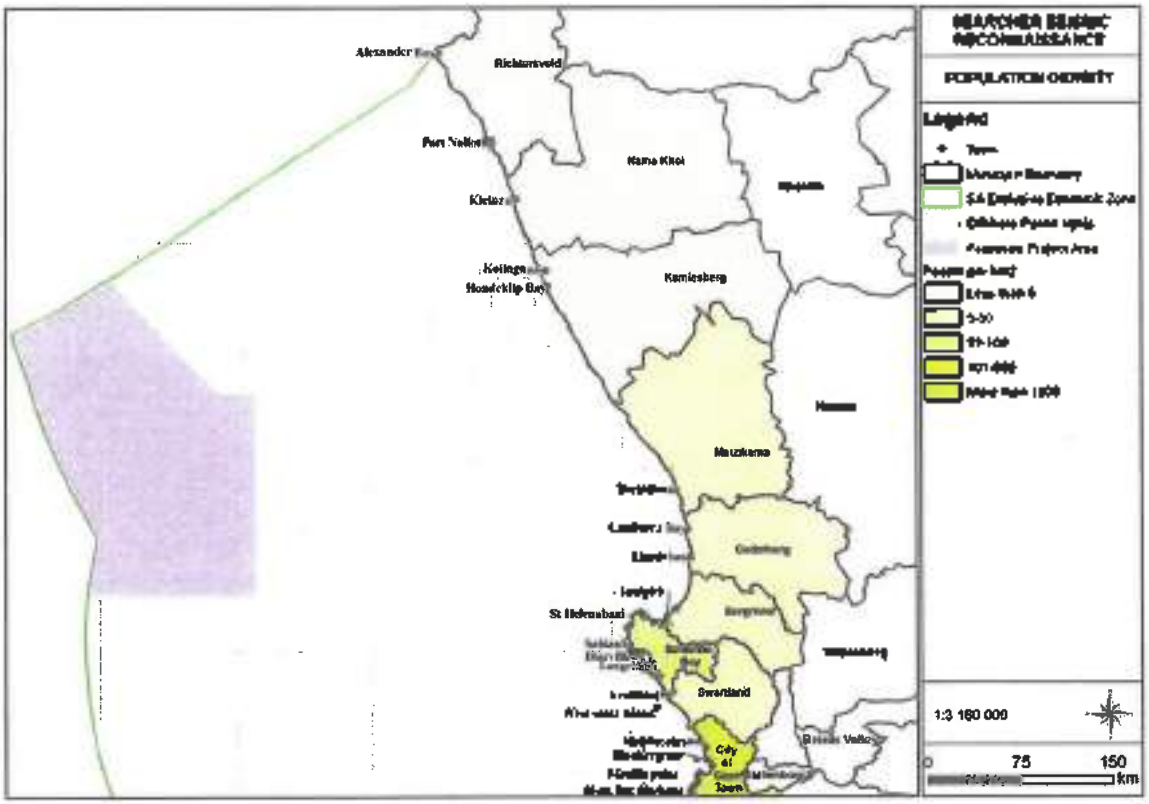

Figure 4: People per ward (source: Census 2011)

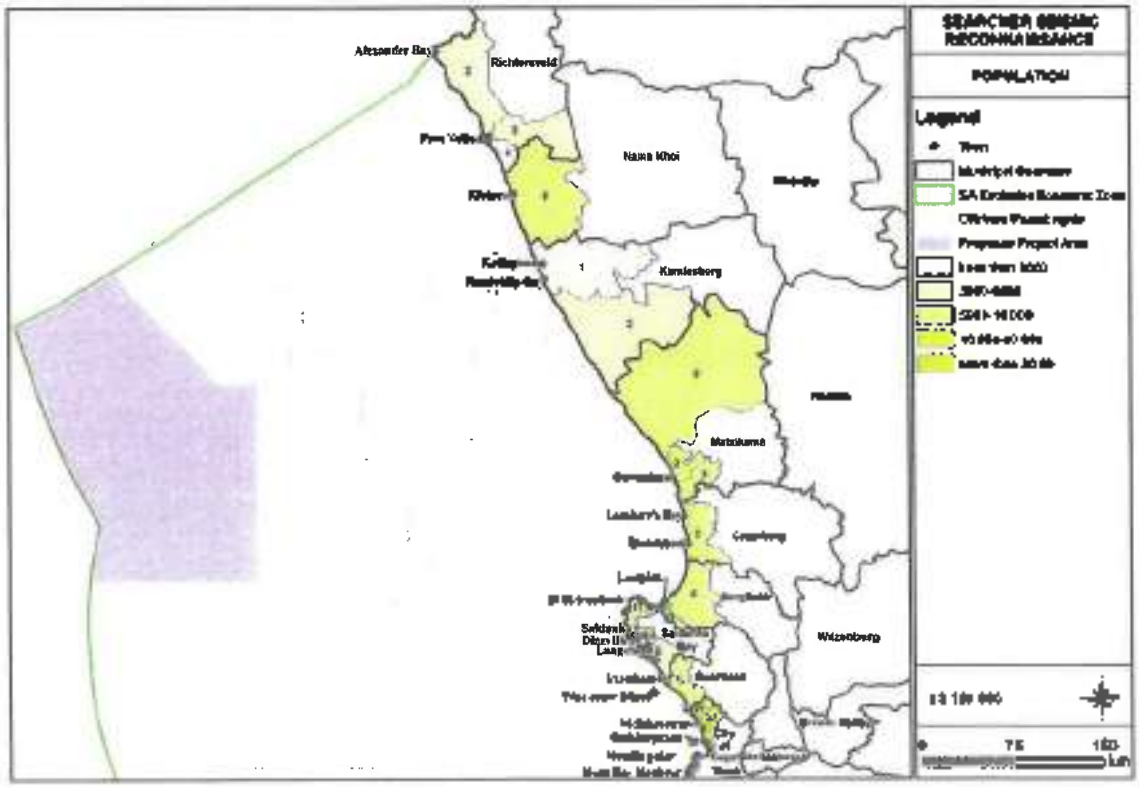

5113

The number of households in the study area has increased on all levels (Table 2). The proportionate increase in households were greater than the increase in population on all levels. The greatest proportional increases in households were in the Swartland and Saldanha Bay Local Municipalities. The average household size has shown a decrease on all levels, which means there are more households, but with less members.

Table 2: Household sizes and growth estimates (sources: Census 2011, Community Survey 2016)

Area	Households 2011	Households 2016	Average household size 2011	Average household size 2016	Growth in households (%)
Northern Cape	301,495	353,709	3.80	3.38	17.35

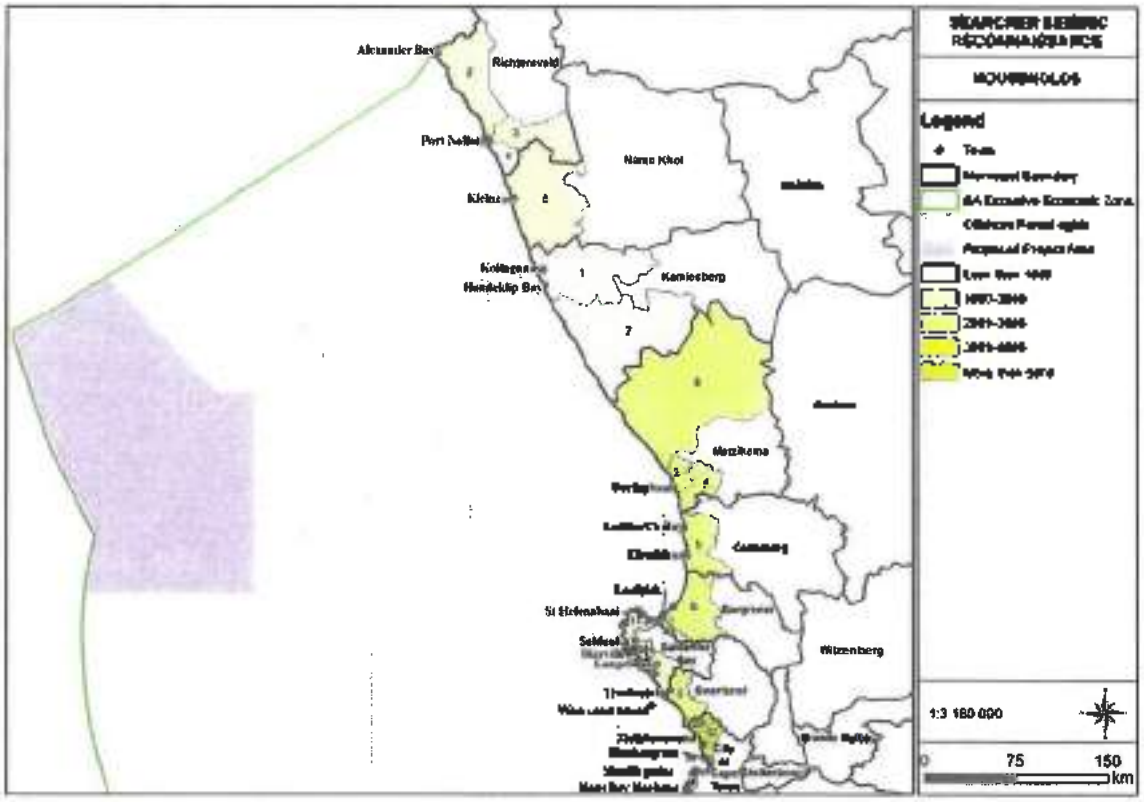
City of Cape Town Metropolitan	*1,068,573*	*1,264,849*	*3.50*	*3.17*	*18.37*

Figure 5 shows the number of households per ward. The wards in the Kamiesberg Local Municipality have the fewest people per ward.

FCS

Figure 5: Households per ward (source: Census 2011)



The total dependency ratio is used to measure the pressure on the productive population and refer to the proportion of dependents per 100 working-age population. As the ratio increases, there may be an increased burden on the productive part of the population to maintain the upbringing and pensions of the economically dependent. A high dependency ratio can cause serious problems for a country as the largest proportion of a government's expenditure is on health, social grants and education that are most used by the old and young population.

The Kamiesberg Local Municipality has the highest total dependency ratio (Table 3), while in the Richtersveld Local Municipality have the lowest. Employed dependency ratio refers to the proportion of people dependent on the people who are employed, and not only those of working age. The employed dependency ratio for the Kamiesberg and Nama Khoi Local Municipalities are the highest. This suggests high levels of poverty in these areas. Figure 6 and Figure 7 show the total and employed dependency ratios on a ward level.

Table 3: Total dependency ratios (source: Census 2011).

Area	Total dependency	Youth dependency	Aged dependency	Employed dependency
Northern Cape	55.75	46.94	8.80	75.32
Namakwa DM	*51.23*	*39.01*	*12.22*	*70.92*
Richtersveld LM	*42.51*	*33.96*	*8.55*	*61.38*
Ward 2	36.82	32.89	3.93	56.70
Ward 3	39.54	32.95	6.59	64.57

Figure 6: Total dependency ratios (source: Census 2011)

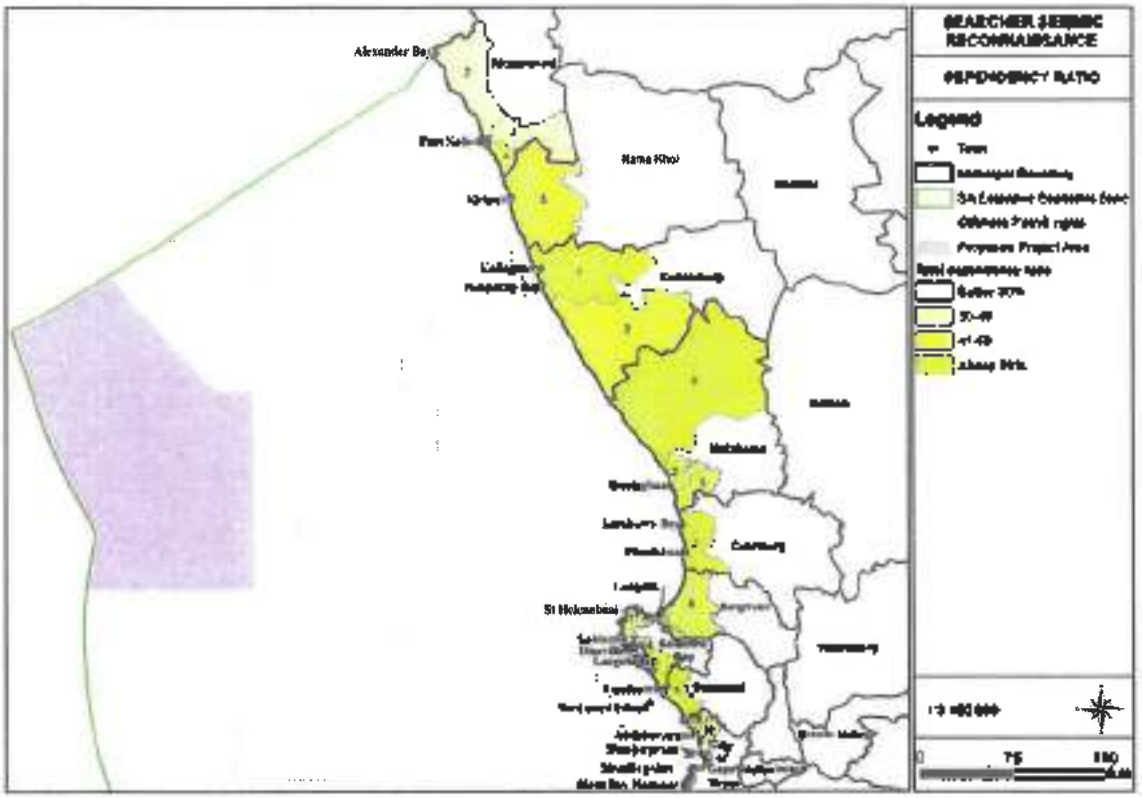

Figure 7: Employed dependency ratio (source: Census 2011).

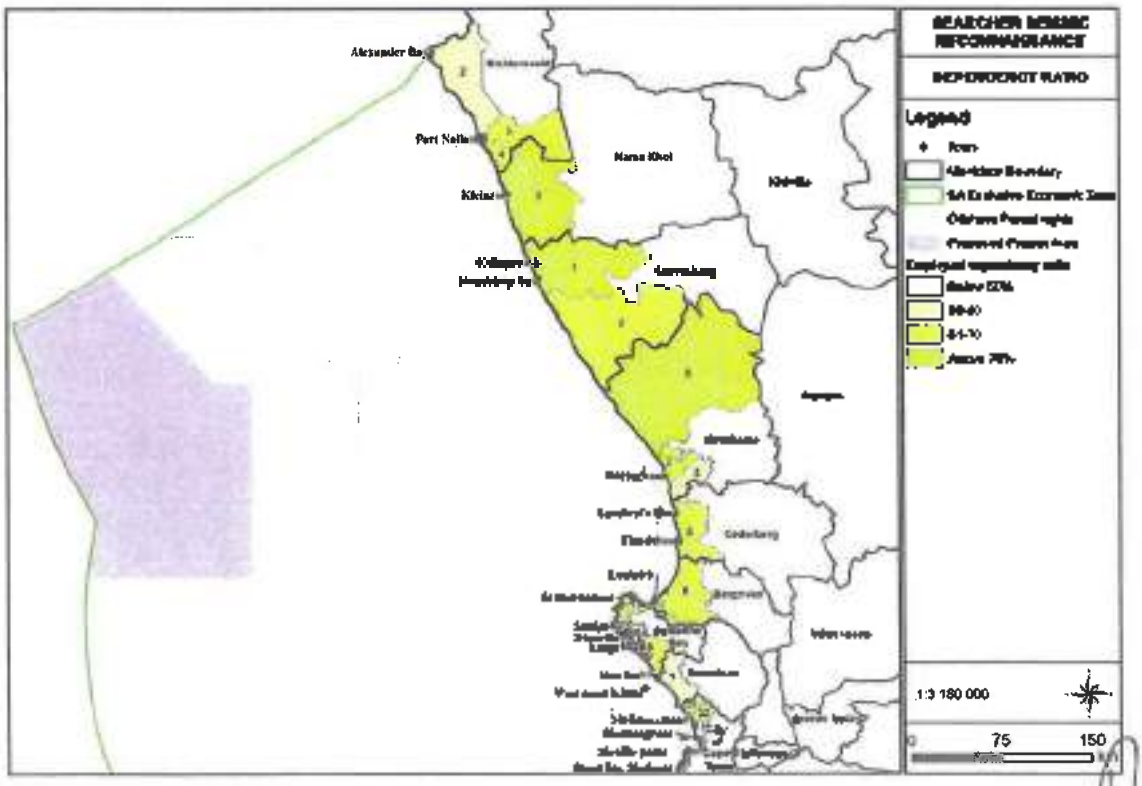

Poverty is a complex issue that manifests itself in economic, social, and political ways and to define poverty by a unidimensional measure such as income or expenditure would be an oversimplification of the matter. Poor people themselves describe their experience of poverty as multidimensional. The South African Multidimensional Poverty Index (SAMPI) (Statistics South Africa, 2014) assess poverty on the dimensions of health, education, standard of living and economic activity using the indicators child mortality, years of schooling, school attendance, fuel for heating, lighting, and cooking, water access, sanitation, dwelling type, asset ownership and unemployment.

The poverty headcount refers to the proportion of households that can be defined as multi-dimensionally poor by using the SAMPI's poverty cut-offs (Statistics South Africa, 2014). The poverty headcount has increased on all levels since 2011 (Table 4), indicating an increase in the number of multi-dimensionally poor households.

The intensity of poverty experienced refers to the average proportion of indicators in which poor households are deprived (Statistics South Africa, 2014). The intensity of poverty has increased slightly on all levels. The intensity of poverty and the poverty headcount is used to calculate the SAMPI score. A higher score indicates a very poor community that is deprived on many indicators. The SAMPI score has decreased in the Northern Cape (Table 4) as well as the Northern Cape municipalities included in the study. In the Nama Khoi Local Municipality, the score remained the same although there was a slight increase in the intensity of the poverty. In the Western Cape the SAMPI score decreased on a provincial level, but in the West Coast District Municipality it has increased.

Table 4: Poverty and SAMPI scores (sources: Census 2011 and Community Survey 2016).

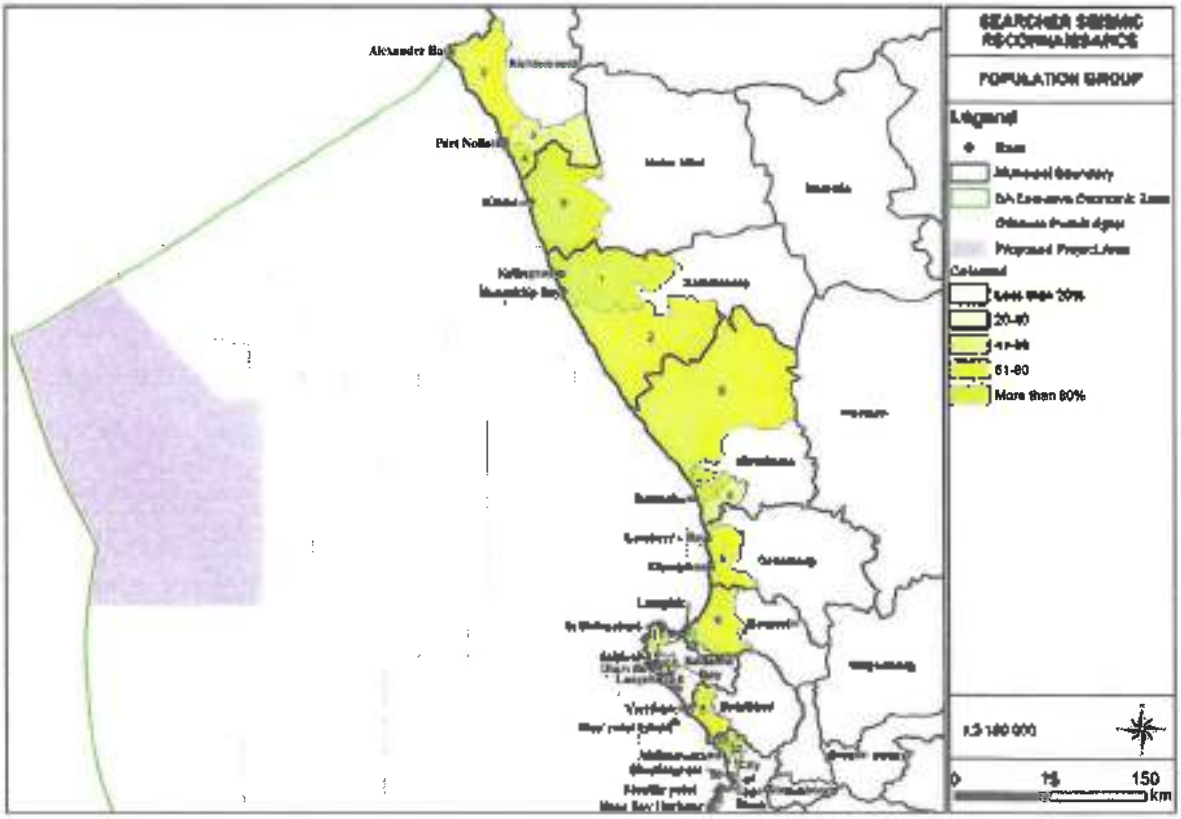
5.2.2 Population composition, age, gender and home language

The majority of the people living in wards adjacent to the ocean are classified as belonging to the Coloured population group (Figure 8). The Coloured population group include Khoe and San people who in general find this classification offensive and they do not identify as such.

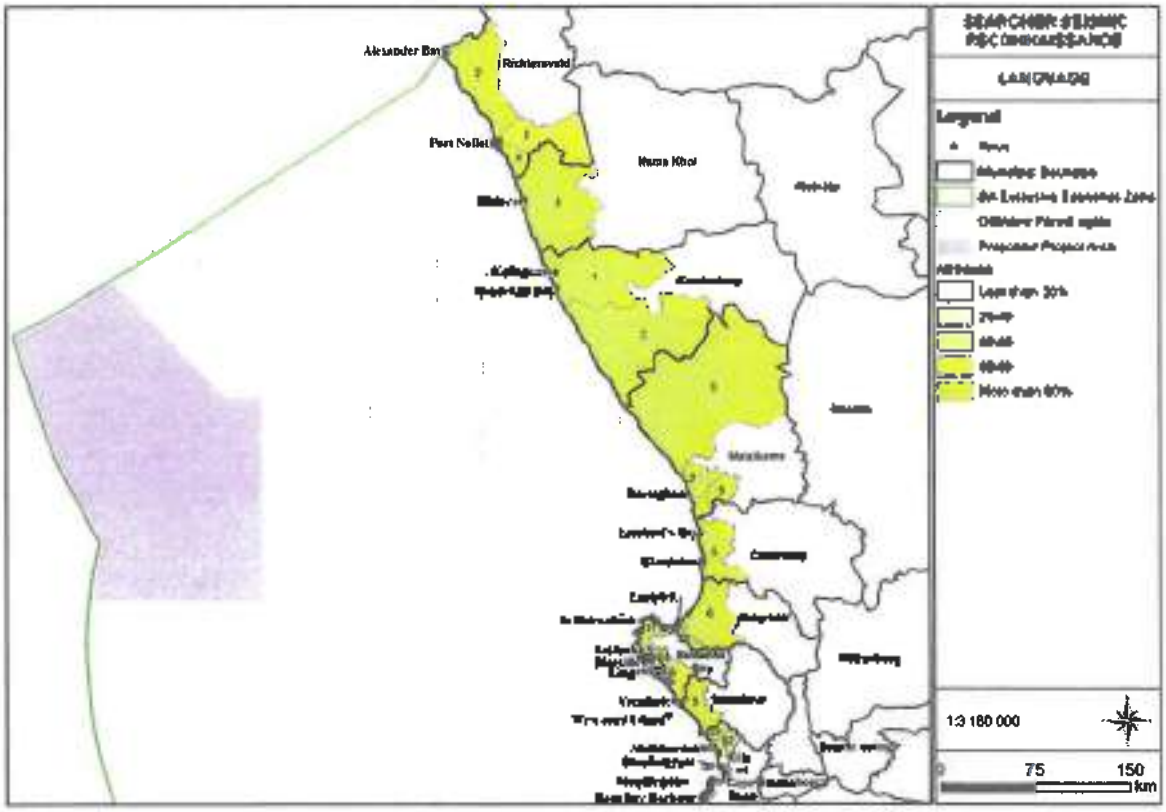
Figure 8: Classified as Coloured (shown in percentage, source: Census 2011)



The Kamiesberg Local Municipality has the highest average age (33.17 years) while the Saldanha Bay Local Municipality has the lowest (29.86 years). Average age varies on a ward level.

The gender distribution is more or less equal in most municipal areas, except for the Richtersveld Local Municipality where there is a bias towards males. This is most likely due to mining activities that are taking place in the area. On a ward level, most people have Afrikaans as home language (Figure 9).

Figure 9: Home language Afrikaans (shown in percentage, source; Census 2011)

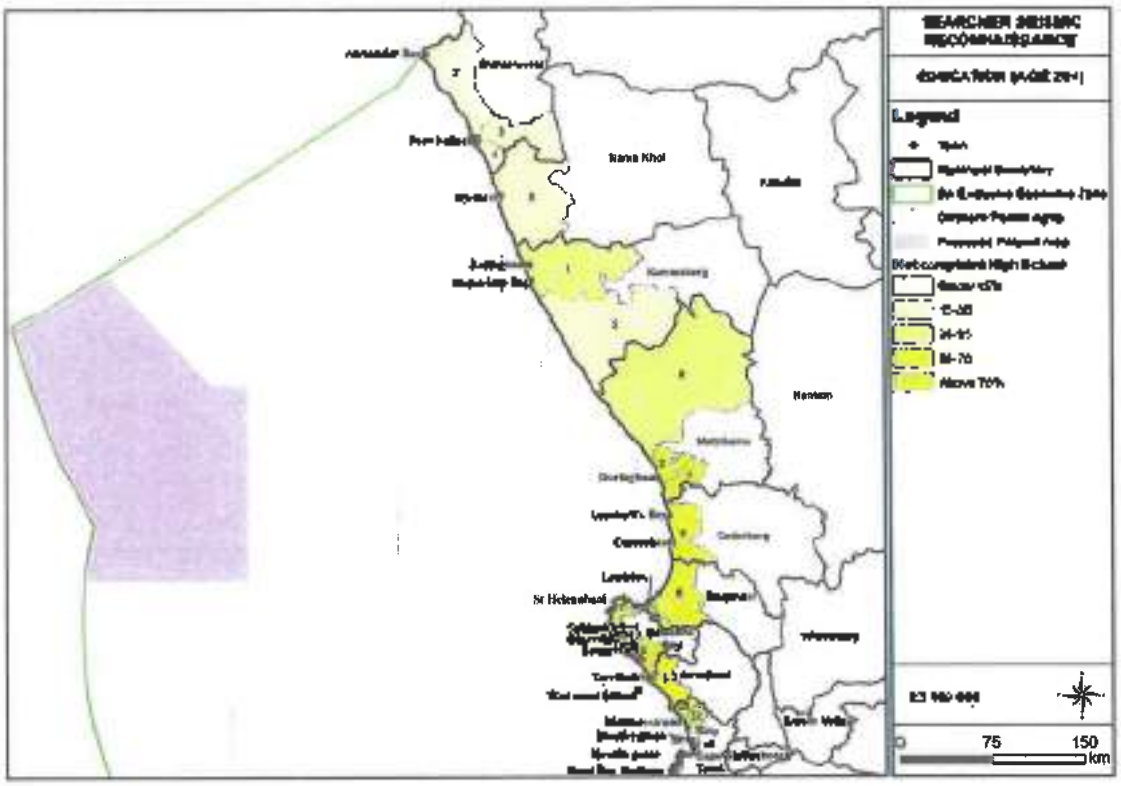


5.2.3 Education

The highest proportion of people who did not complete high school is in the Saldanha Bay (73.59%) and the Swartland (72.83%) Local Municipalities while the Matzikama (32.7%) and Nama Khoi (37.37%) Local Municipalities have the lowest proportion of people that did not complete high school (Figure 10).

508

Figure 10: Proportion of people that did not complete secondary school (shown in percentage, source: Census 2011).



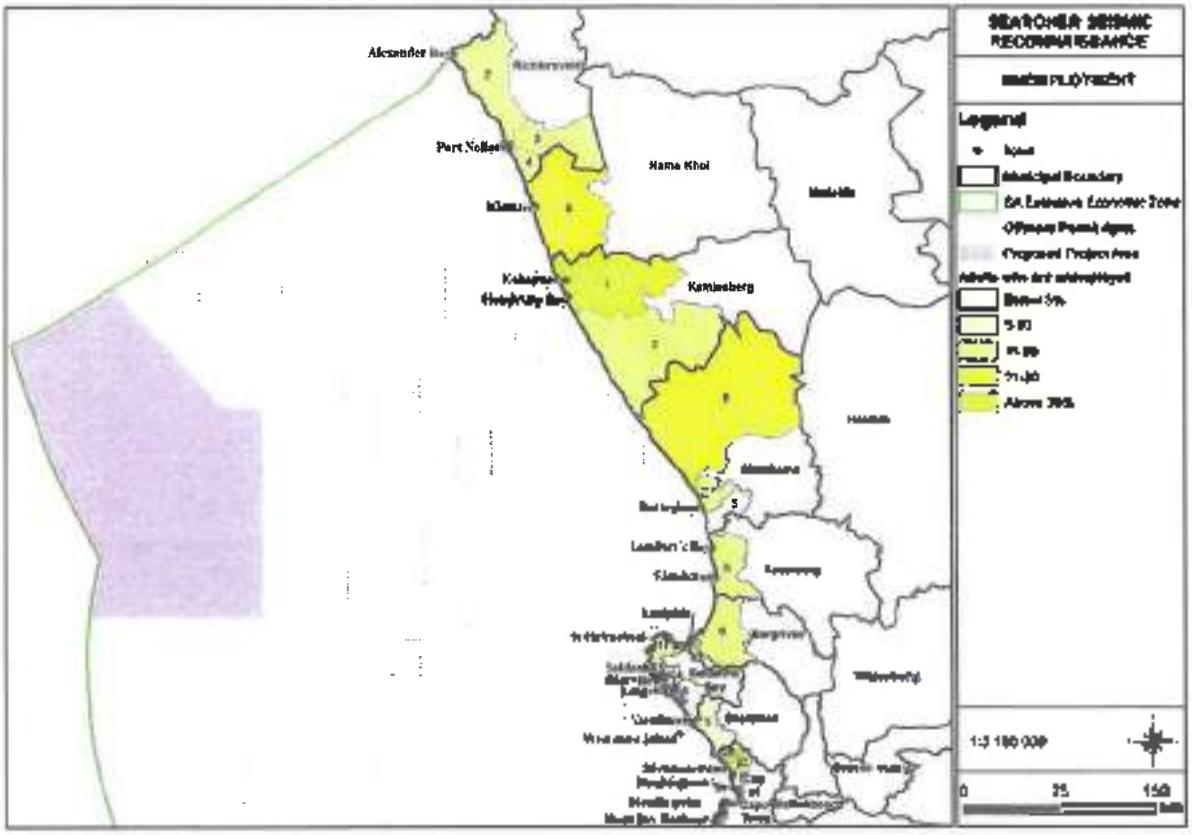
5.2.4 Employment

In 2011 the area with the highest proportion of unemployed people was ward 1 in the Kamiesberg Local Municipality where Hondeklip Bay is located (

Figure 11). The proportion of unemployed people include those actively seeking for work as well as discouraged work seekers. The majority of people who are working, is employed in the formal sector.

5603

Figure 11: Proportion of adults that are unemployed (shown in percentage, source: Census 2011).

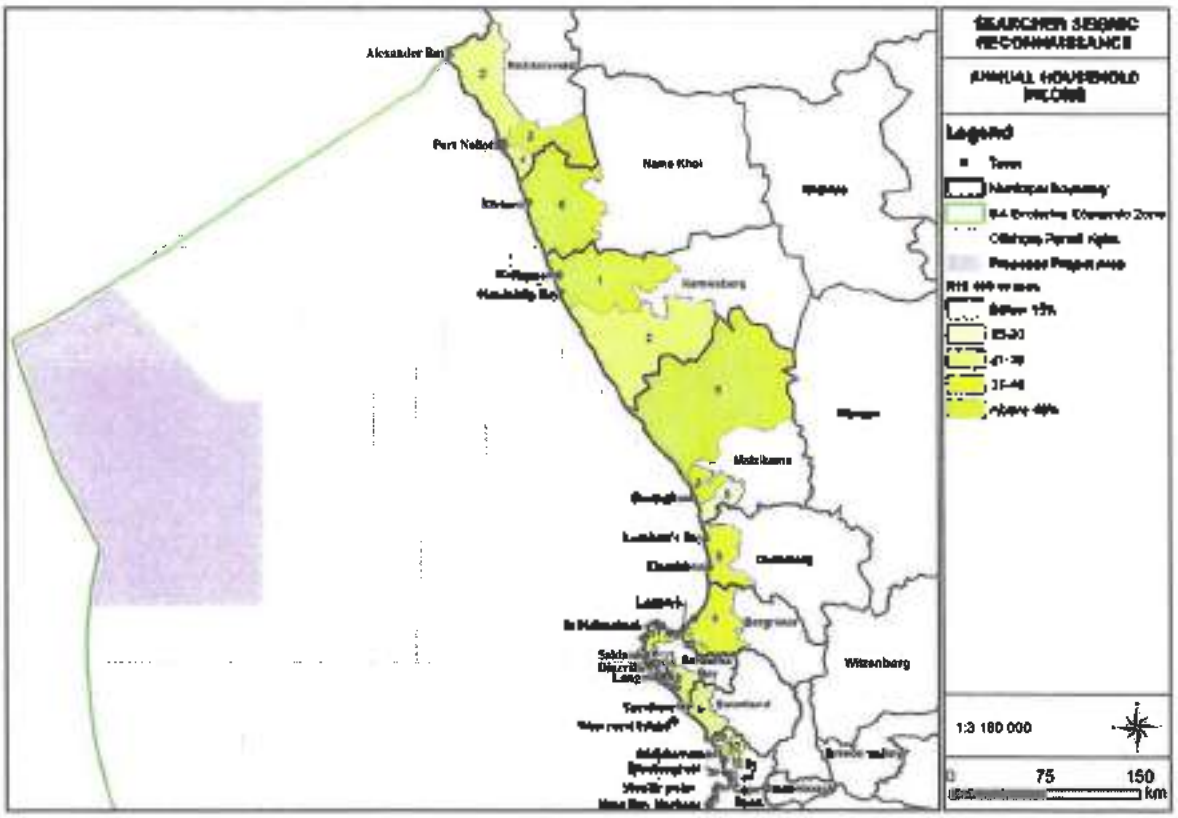


5.2.5 Household income

In 2011 almost a third of households on municipal level had an annual household income of R19 600 or less, with great variation between wards (Figure 12). Statistics South Africa (2015) has calculated the Food Poverty Line (FPL) for the Northern Cape Province as R310 per capita per month for 2011 where the FPL is the Rand value below which individuals are unable to purchase or consume enough food to supply them with the minimum per-capita-per-day energy requirement for good health. The FPL is one of three poverty lines, the others being the upper bound poverty line (UBPL) and the lower bound poverty line (LBPL). The LBPL and UBPL both include a non-food component. Individuals at the LBPL do not have enough resources to consumer or purchase both adequate food and non-food items and are forced to sacrifice food to obtain essential non-food items, while individuals at the UBPL can purchase both adequate food and non-food items. The LBPL for the Northern Cape Province was R457 per capita per month in 2011 and the UBPL R705 per capita per month

respectively. The FPL for Western Cape was R352 per capita per month, the LBPL was R545 and the UPL was R804. Based on this, a household with four members needed an annual household income of approximately R17 000 in 2011 to be just above the FPL. When comparing this with the SAMPI data it seems as if there are more households below the poverty lines in the area than who are multi-dimensionally poor. This is due to the poverty lines using a financial measure and do not take into consideration payment in kind and livelihood strategies such as subsistence farming. If these were to be converted into a Rand value, the poverty line picture may have a closer resemblance to the SAMPI data.

Figure 12: Proportion of households with an annual income of R19 600 or less in 2011 (shown in percentage, source: Census 2011).



5.2.6 Housing

The majority of households live in areas that are classified as urban, except in the Matzikama Local Municipality (Figure 13). The majority of people live in formal dwellings that that are houses or structures that are on a separate stand or yard. The incidence of informal dwellings is relatively low (

Figure 14), except for Ward 1 of the Saldanha Bay Local Municipality where the majority of people live in informal dwellings. Wards 32 and 74 also have a relatively large proportion of households living in informal dwellings.

Figure 13: Proportion of households that live in urban areas (shown in percentage, source: Census 2011).

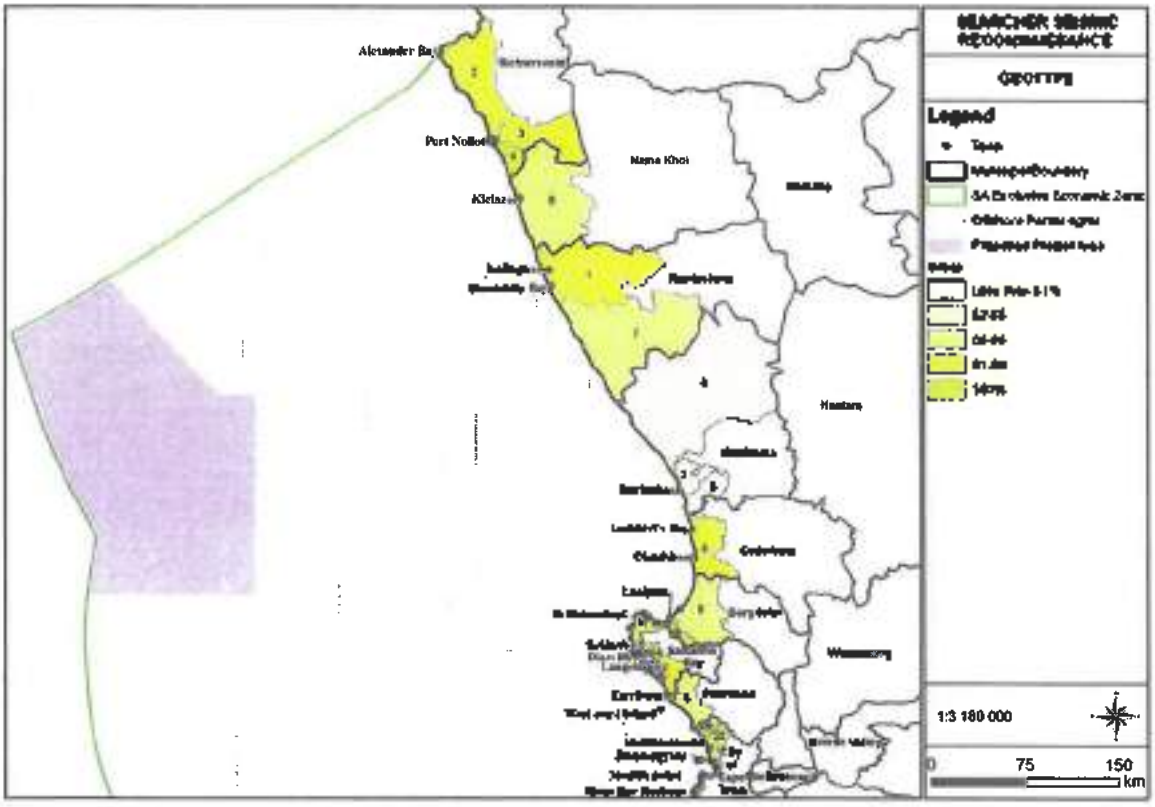


Figure 14: Proportion of households that live in informal dwellings (shown in percentage, source: Census 2011).

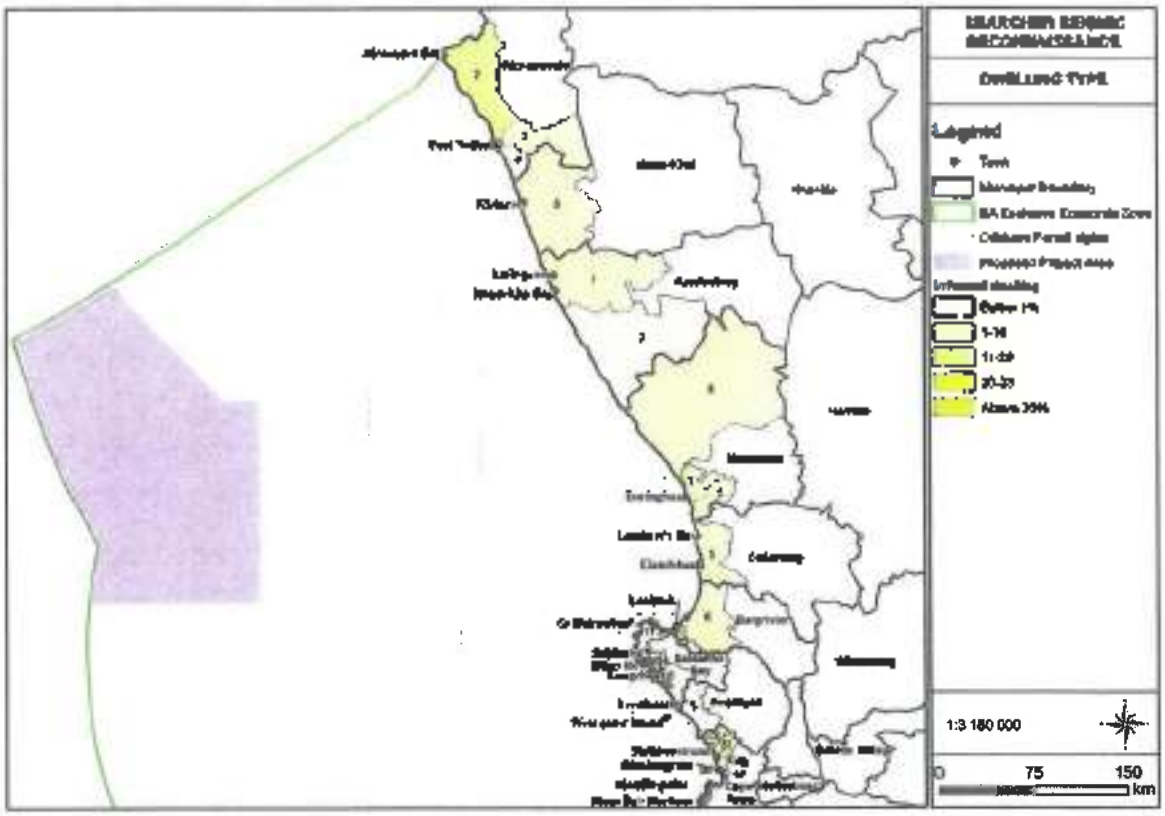


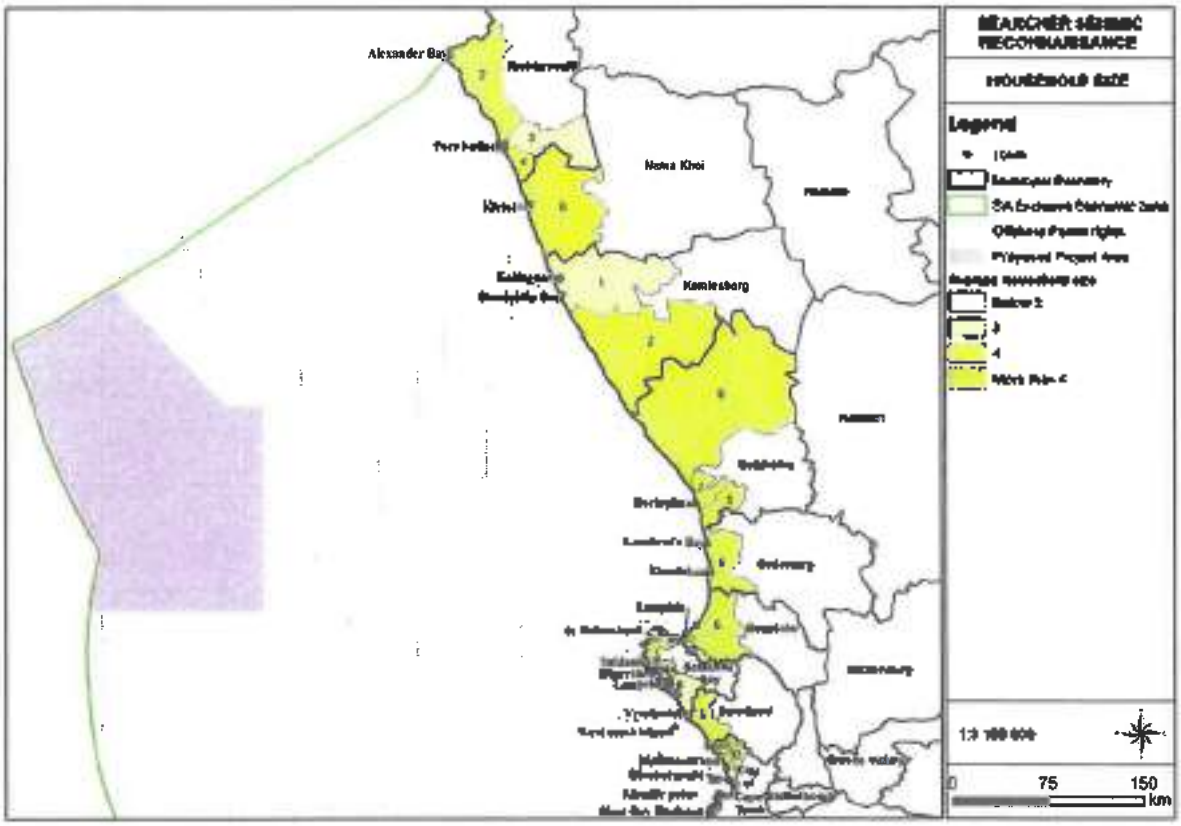
5.2.7 Household size

The average household size in the wards vary between 1.96 people per household and 4.86 people per household (

Figure 15).

3608

Figure 15: Average household sizes (source: Census 2011).

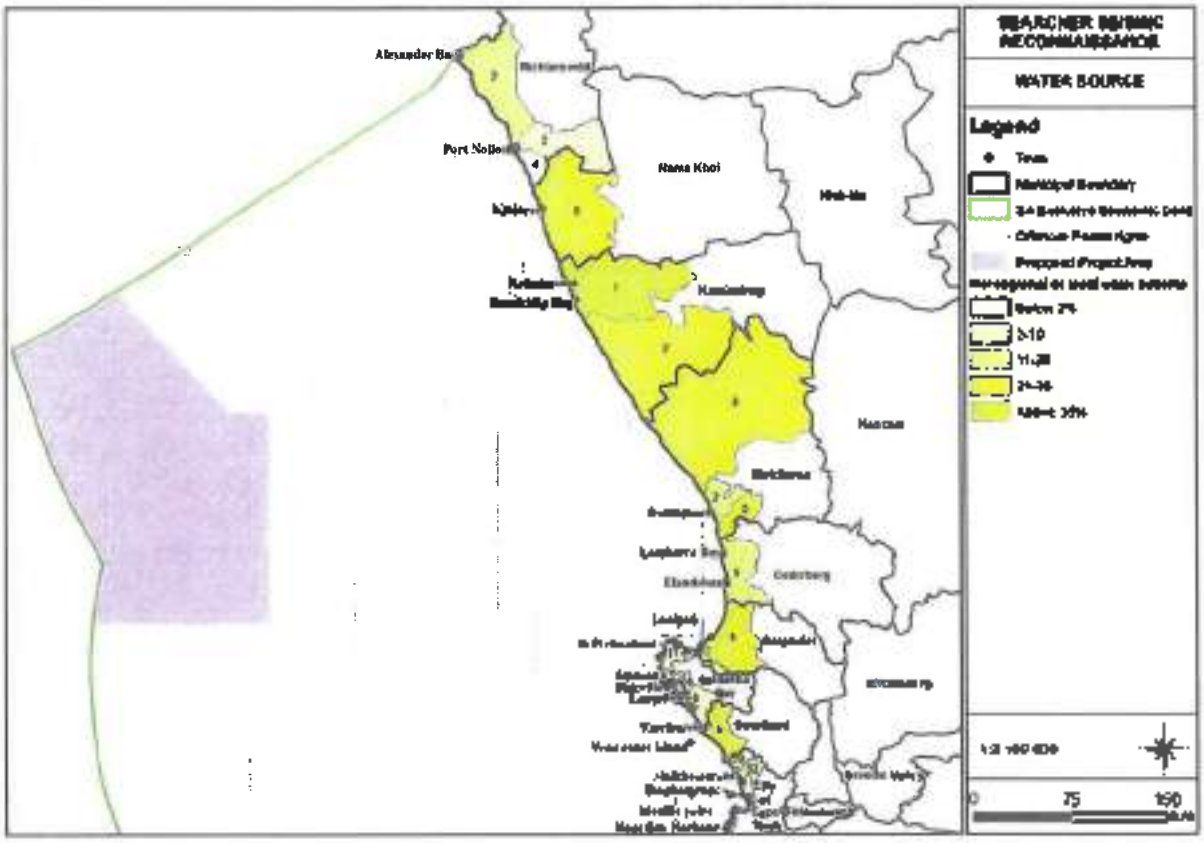


5.2.8 Access to water and sanitation

Access to piped water, electricity and sanitation relate to the domain of Living Environment Deprivation as identified by Noble et al (2006). Most households get their water from a regional or local water scheme, with the lowest incidence in Ward 1 of the Kamieskroon Local Municipality where Hondeklip Bay is located |

Figure 16).

Figure 16: Proportion of households that does not get water from a regional or local water scheme (shown in percentage, source: Census 2011).



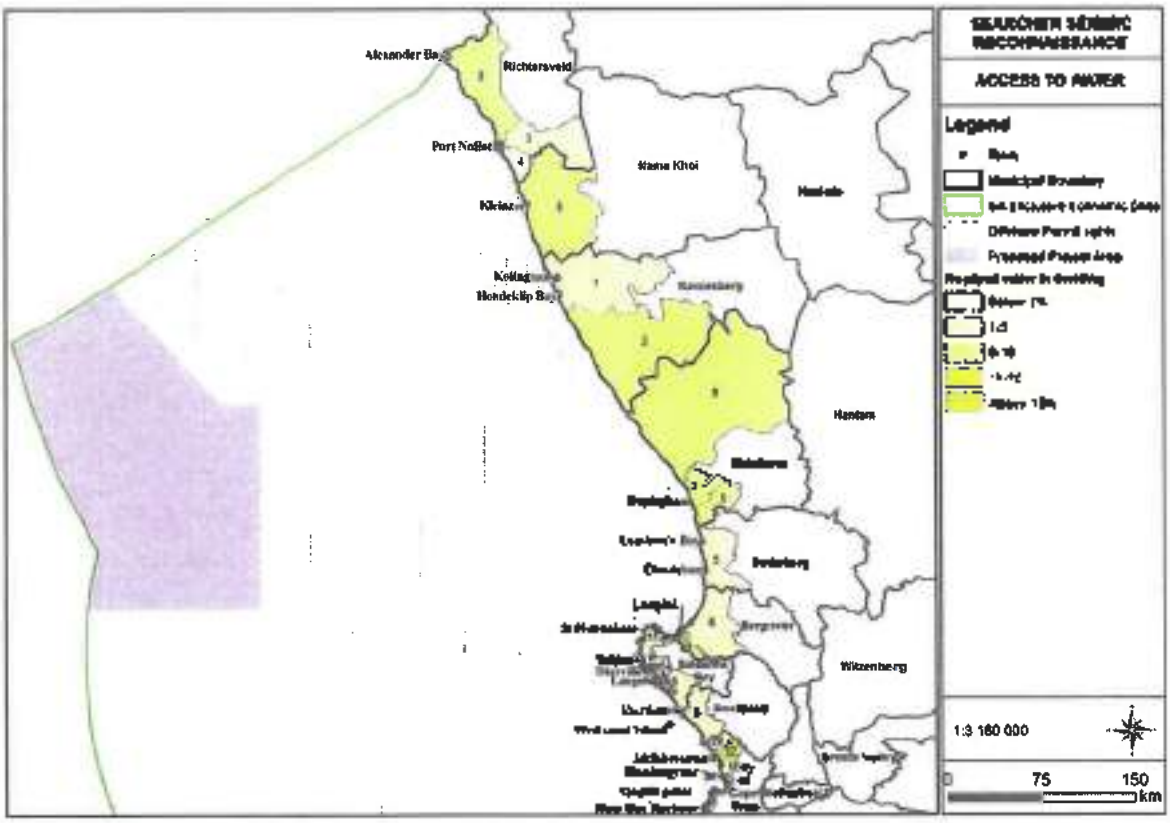
The incidence of access to piped water inside the dwelling varies and tend to be lower in the Northern Cape municipalities (

5008

Figure 17).

6/08

Figure 17: Proportion of households that does not have piped water in the dwelling (shown in percentage, source: Census 2011).

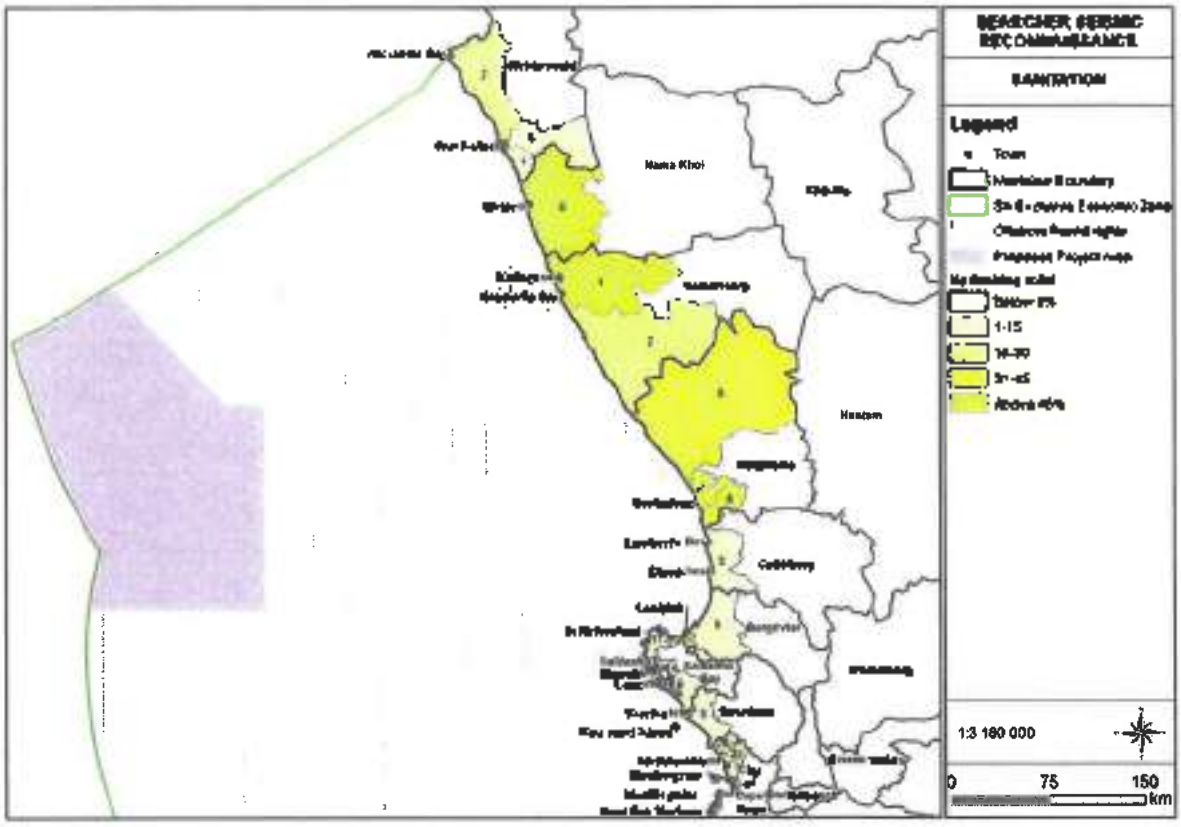


Access to a flush toilet is in general lower in the Northern Cape Municipalities (

Figure 18).

EOS

Figure 18: Proportion of households that does not have a flush toilet (shown in percentage, source: Census 2011).



5.2.9 Energy

Electricity is seen as the preferred lighting source (Noble et al, 2006) and the lack thereof should thus be considered a deprivation. Even though electricity as an energy source may be available, the choice of energy for cooking may be dependent on other factors such as cost. The majority of households have access to electricity for lighting purposes (

5409

Figure 19) but a lower proportion use electricity for heating (Figure 20) and cooking (Figure 21) purposes.

Figure 19: Proportion of households that use paraffin, candles, wood or nothing for lighting purposes (shown in percentage, source: Census 2011).

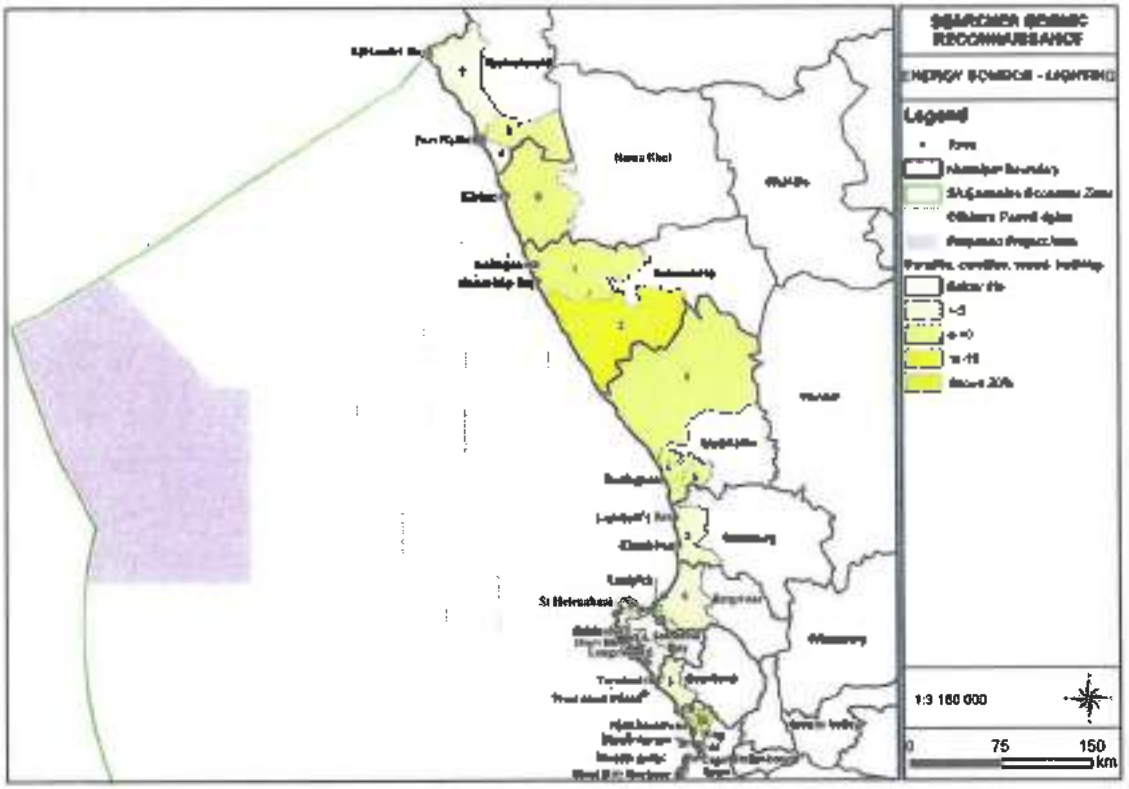


Figure 20: Proportion of households that use paraffin, wood, coal, dung or something else for heating purposes (shown in percentage, source: Census 2011).

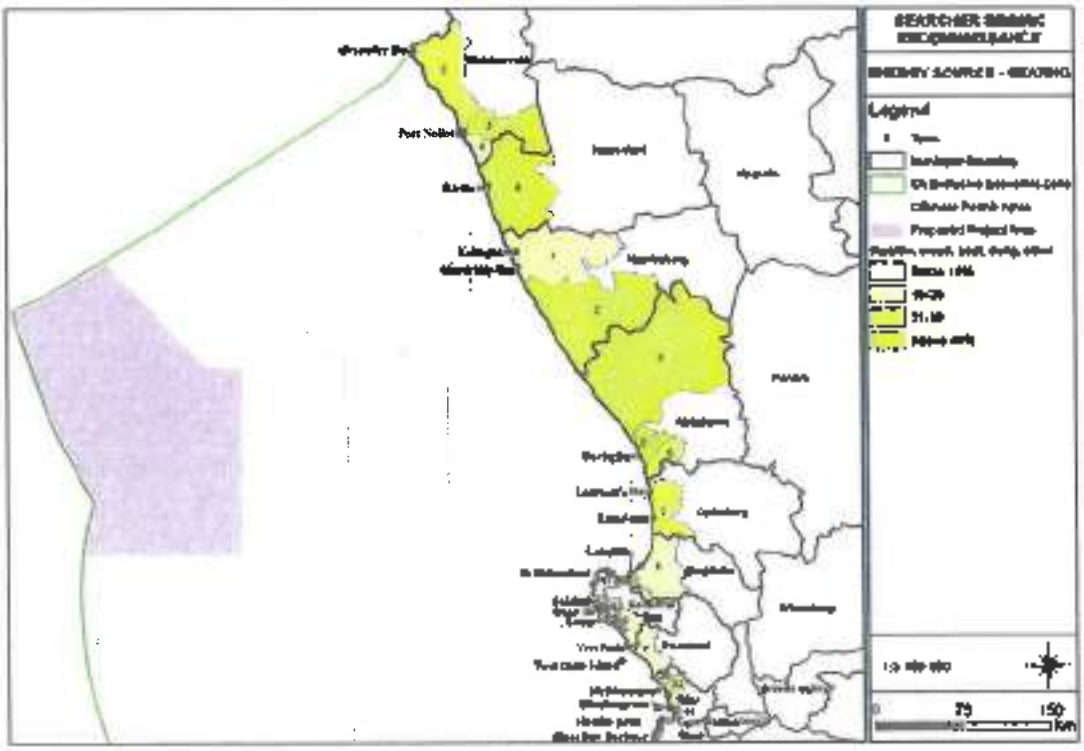

Figure 21: Proportion of households that use paraffin, wood, coal, dung or something else for cooking purposes (shown in percentage, source: Census 2011).

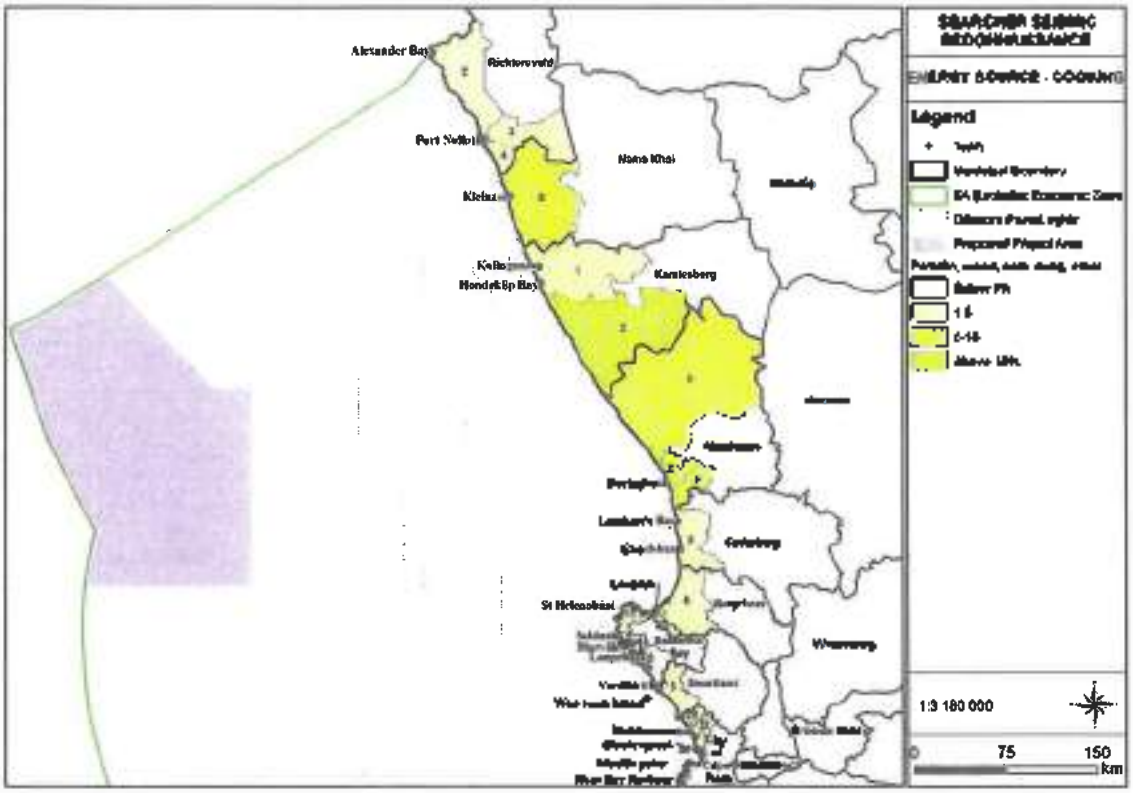

5628

6 Stakeholder Identification and Analysis

6.1 Approach

Stakeholders include all individuals and groups who are affected by, or can affect, a given operation. Stakeholders consist of individuals, interest groups and organizations (Vanclay, Esteves, Aucamp & Franks, 2015). Stakeholder analysis is a deliberate process of identifying all stakeholders of a project - the individuals and groups that are likely to impact or be impacted by it - and understanding their concerns about the project and/or relationship with it (Vanclay et al, 2015). Stakeholder analysis assists the proponent with understanding the local cultural and political context. It is acknowledged that different stakeholder groups have different interests, and that there are individual differences within stakeholder groups. The purpose of this section of the report is to introduce the stakeholder groups that will be affected by the proposed projects. The following stakeholder groups were identified and their interest in the projects will be discussed briefly in the section below.

6.2 List of stakeholders

The following stakeholders that may have an interest in or affected by the proposed Searcher seismic survey project have been identified:

Figure 22: Detail of Stakeholder Groups.

Stakeholder Grouping	Organisation
Internal Stakeholders	
Searcher Geodata UK Ltd	**Searcher Staff** involved with the **project**
Seiche	Seiche Staff involved with the project
Government	
Governmental departments and directorates	• Western Cape Provincial Government • Northern Cape Provincial Government • Petroleum Agency of South Africa • Department of Environment, Forestry and Fisheries • Department of Mineral Resources and Energy • South African Navy Hydrographic Office (SANHO) • Namaiwa District Municipality • West Coast District Municipality • City of Cape Town Metropolitan Municipality • Richtersveld Local Municipality • Nama Khoi Local Municipality • Kamiesberg Local Municipality • Matzikama Local Municipality

59 18

Stakeholder Grouping	Organisation
	• Cederberg Local Municipality • Bergrivier Local Municipality • Saldanha Bay Local Municipality • Swartland Local Municipality • South African Heritage Resources Agency (SAHRA)
State-owned entities and regulators	• Transnet National Ports Authority • South African Maritime Safety Authority
Business	
Fishing Industry	Fishing industry associations Commercial fishing sectors: demersal trawl, midwater trawl, demersal hake longline, demersal shark longline, small pelagic purse-seine, large pelagic longline, tuna pole-line, traditional line fish, West Coast rock lobster, small-scale fisheries, beach-seine and gillnet fisheries (netfish), fisheries research
Petroleum and Gas Industry	Various companies that have expressed interest in oil or gas exploration in the West Coast area Companies conducting seismic surveys
Other industries	Industries providing support services such as equipment, fuel, accommodation, meals and other supplies
Environmental	
Environmental interest groups	Green Connection Coastal Links We Are South Africans Other relevant environmental interest groups
Societal	
Social Organizations	Masifundise Development Trust Small-scale fisheries cooperatives such as Aukatowa small scale fisheries cooperative Small-scale fishing communities such as Steenbergs Cove ABALOBI Coastal Justice Network Community forums (e.g., employment, youth)
Residents/ Community	
Local coastal communities	Hout Bay, Saldanha Bay, St Helena Bay, Lambert's Bay, Hondeklip Bay, Port Nolloth, Velddrif, Paternoster, Jacobsbaai, Langebaan, Grotto Bay, Elands Bay, Strandfontein, Doringbaai
Local indigenous people	Nama, Khoi and San groups, including Cochoque Tribal House, the Guriqua Tribe and the Katz Korana Royal House

The identified level of interest of each stakeholder helps assist with designing the stakeholder engagement strategy for the project, and to decide how much time to devote to engaging with each stakeholder or group. The engagement levels required for each group of stakeholders as revealed through this analysis may be more than consultation, for example they may include partnerships, involvement in community

BW3

development plans or community monitoring, strategic planning, or any other activity. Knowing the needs, issues and expectations of affected stakeholders assist with building and retaining good relationships with them, and with managing their expectations.

Table 5 below plots the stakeholders according to their ability to influence the company's activities (horizontal axis) and the degree to which they are affected by the proposed Searcher activities, whether the impact is social, economic or environmental (vertical axis). In instances where the impact or influence is potentially significant individual stakeholder groups/organisations have been used. All other groupings are used in general.

Table 5: Stakeholder matrix.

Degree to which they are impacted on	Ability to influence company's activities: Low	Medium	High
High	Local coastal communities Local indigenous people	Fishing Industry	Searcher Geodata UK Ltd Seiche Petroleum and Gas Industry
Medium		Other industries Environmental interest groups Social Organizations	Governmental departments and directorates State-owned entities and regulators
Low			

When considering the project affected stakeholders it is important to consider the potential impacts after the seismic surveys are conducted. The stakeholders that will be impacted on most but have the least ability to influence the company's activities are local coastal communities and indigenous people, who is also seen as the most vulnerable group. Their fears about future impacts and uncertainty about the potential impacts on their livelihoods are already causing an impact on their emotional and physical wellbeing. There is a power imbalance between Searcher and the local communities. It is therefore of great importance that Searcher and the local

communities communicate frequently in an open and honest manner to avoid a standoff. Communities are supported by environmental and social interest organisation, and these organisations have the ability to mobilise community activists and fund potential court cases.

The community perception is that the government has already decided that it will allow this and similar projects to continue. The government is seen as a powerful stakeholder with significant ability to influence the decision-making process.

The placement of stakeholders in the stakeholder matrix may change with time, and it should be revisited frequently.

5128

7 Social risk

Social risk is a confusing term because it has different meanings in different discourses. In the SIA/corporate project discourse, 'social risk' is a largely similar concept to 'non-technical risk' and is the preferred term (Vanclay et al, 2015). The World Bank defines social risk as "the possibility that the intervention would create, reinforce or deepen inequity and/or social conflict, or that the attitudes and actions of key stakeholders may subvert the achievement of the development objective, or that the development objective, or means to achieve it, lack ownership among key stakeholders". For the Bank, social risk is considered to be both risk (threats) to the success of the project, but also risk (social issues) created by the project, which in turn become threats to the project. In a corporate setting, social risk can be regarded as the business risks (e.g. extra costs) to the company that arise from any social impacts or social issues created by the project, such as through unforeseen costs of mitigation, future litigation and/or compensation pay-outs, worker strikes, retaliatory acts of sabotage, and reputational harm (Vanclay et al, 2015).

Non-technical risks relate to the managerial, legal, social and political issues faced by a project, in contrast to the technical risks (i.e. the physical, structural, engineering and environmental risks). Non-technical risks are potentially serious financial risks to a project because of the protest actions local communities can take, and therefore should be considered and addressed (Vanclay et al, 2015).

Risk inevitably involves a concern with good and bad outcomes (Eiser, 2004). Such values will be implicit in any exchange. What any audience will be listening for is an indication of what they need to do – not simply for a prediction of what consequences may or may not happen, but also for an indication of how good or bad these consequences will be, and what they, or anyone else, is expected to do about it. The best way to communicate risk is to adopt a less didactic model of communication. It is already widely recognised that, to be effective, the communication of risks cannot be merely one-way. It must involve exchange and interaction between all parties. There are obstacles to putting such good intentions into practice. The 'experts' need to be prepared to give up not only time, but also some of their power (Eiser, 2004).

The 'public' need to be willing to be engaged in the decision process and take some responsibility for the outcomes if these have been shaped to take account of their views. All this can be costly, in terms of time, patience and the risk of disappointment if not everything one wants could be achieved. The real advantage over the traditional, less consultative, approach is that the debate or discussion can focus on what people want to know and issues of value, rather than merely probability can be considered (Eiser, 2004).

Another important social factor to consider is the "social licence to operate". In 2003 Pierre Lassonde drew attention to the observation that "*Without local community support, your project is going nowhere.*" He described social license as "*...the acceptance and belief by society, and specifically local communities, in the value creation of activities*". Social licence cannot be obtained by going to a government ministry and making an application or simply paying a fee. It requires far more than money to truly become part of the communities in which a company operates (Lassonde 2003). A primary objective of gaining a social license is to minimize project risk. "*Successful operations require the support of the communities in which they operate now, and in the future, to ensure continued access to land and resources*" (Render 2005). The social license to operate can be further described as the degree of match between stakeholders' individual expectations of corporate behaviour and companies' actual behaviour.

Seismic surveys are currently a controversial and political subject in South Africa. On 1 September 2022 there was a high court ruling against Shell conducting seismic surveys. The ruling found that coastal communities were not properly consulted (Judgement on Sustaining the Wild Coast vs Minister of Mineral Resources and Energy and others, 1 Sept 2022). The debate about the potential impacts of seismic surveys has been ongoing and in the public domain for the last couple of years but intensifying in the second half of 2022. For many people it is an emotional issue and goes much deeper than scientific research on potential impacts on the marine environment. For some people the core of the issue is the impact on their indigenous and culture rights, their customs and traditions and their livelihoods.

1893

Others feel that the seismic surveys are only the first step and that it will open the door to exploration for oil and gas. They are already aware of changes in the marine environment due to existing impacts such as shipping traffic, mining in the sea, climate change and over-fishing. Their concerns are related to the potentially negative impacts associated with the oil and gas industry, especially from an environmental perspective and the impact that using oil and gas will have on climate change. They feel that South Africa must move away from fossil fuels and act in line with the government's policies and international commitments in this regard. There are also people with the opinion that a developing country like South Africa cannot afford to not explore for oil and gas. Their feeling is that the energy transition will take some time, and that oil and gas are better than coal mines.

It is a contentious issue that can potentially cause damage to the social fabric of local communities, but also lead to civil unrest and reputational damage. From a social perspective these social risks must be highlighted. In the current socio-economic environment associated with the project area, there are significant non-technical risks associated with seismic surveys, irrespective of the company that will conduct the survey.

Table 6: Summary of potential social risks for the proposed project

Risk	Source	Motivation
Opposition to the project through appeals and court cases causing a significant delay in the procast	Local indigenous communities and fishers Environmental NGOs Social justice groups	During the SIA consultation process and as seen in the South African press it was clear that communities will not welcome seismic surveys. There is an example of a community winning a court case against a company wanting to do the survey. Communities may want to appeal the outcome of the EIA process and will resort to legal means if required because they know that resources are available to them from NGOs. These appeals and legal processes may cause a significant delay in the authorisation process which will have knock on effects.
Damage to corporate reputation	Local indigenous communities and fishers	Searcher's corporate reputation can be damaged if communities feel that the process has not been conducted in what the communities see as a meaningful manner.

5128

		There is a history tension between the Searcher and some of the communities, and this has attracted media attention in the past, so there is a chance that this may reach the media for whatever reasons again. This may impact Searcher on an international level, as rights groups may be concerned about grassroots impacts, human rights and social and environmental justice, and the shares are influenced negatively.
Loss of social license to operate	Local indigenous communities and fishers Environmental NGO's Social Justice groups	Searcher's social license to operate has been impaired by the court interdict in March 2022. Given the media attention surrounding the Shell ruling in September 2022 there is a general mistrust against any company that want to conduct seismic surveys. Communities demand meaningful consultation, which go beyond the requirements of an EIA process. They want to feel that they can make informed decisions and have sufficient time to digest the technical information. Community members expressed misgivings about the government and its ability to protect their interest. They feel that the decision to support the application has already been made.
Community protests and potential for civil unrest.	Local indigenous communities and fishers	Communities feel angry and disempowered. They do not differentiate between the different companies that apply for seismic surveys. They see a different face standing in front of them, sharing similar information, but never providing answers to their questions. They feel that they are not listened to and disregarded. Several coastal communities expressed their frustration. The communities communicate with each other via WhatsApp groups, and there is a strong possibility of social mobilisation that can lead to civil unrest and worse case scenario to violent protests.

Social risk's population-based nature sets it apart from traditional risk events such as cyberattacks, workplace safety incidents, and natural disasters. Traditional risk events impact a distinct set of people, while social risk can impact broad segments of society.

Social risk has five characteristics (Ludke, 2021):

- **Human.** Traditional forms of risk most often manifest themselves because of a discrete event or incident. Social risk is built on who we are as human beings and shaped by socio-economic status, social mobility, community environment and mental health.

- **Dynamic.** Social risk is always evolving and formed by how people react to events and ideas. For example, social risk is not necessarily the pervasive nature of socio-economic inequalities in the global economy, it is how the population react to these inequalities

- **Dispersed.** Social risk is a consequence of today's connected society where nearly everyone has the ability to increase their voice through technology and networks of family, friends, colleagues, and social media followers.

- **Distinctive.** Social risk is unique to each organization because it forms as humans organically react to events and ideas, no two social risk events are alike.

- **Scalable.** Social media platforms amplify public conversations. This accelerates social risk as it can scale very quickly from an isolated idea or conversation into a broader movement.

If Searcher choose to identify and mitigate social risk, the following general recommendations should be considered:

- **Create an ecosystem of diverse partners.** A diverse ecosystem will create an "early warning system" to help identify social risk before it manifests as a threat or crisis—provided you stay engaged with this ecosystem in a genuine dialogue.

- **Ask, don't tell.** When developing a social risk management strategy, getting honest feedback can help you avoid pitfalls and build credibility. Similar to engaging partners, this must be approached by listening rather than telling.

- **Communicate constantly.** In an age of social risk, communicating is not about pushing information to audiences. Rather, it is a methodical approach to all facets of a communications strategy that fosters dialogue.

- **Act with humanity.** Social risk is driven by human emotions that must be respected and appreciated.

Addressing social risk requires looking at its causes from a systemic standpoint, not on an event-by-event basis. The solutions must be focused on the same societal level as its causes, including poverty, injustice, inequality, or misinformation. Social risk touches all of society, and it comes from the perceptions and beliefs all humans have.

8 Description of potential impacts

8.1 Social Impact Assessment

> *"Almost all projects almost always cause almost all impacts. Therefore, more important than predicting impacts is having on-going monitoring and adaptive management."* Frank Vanclay

Considering the statement above, it must be considered that some social impacts will not be discussed in detail and that the focus will be on the most severe impacts. Nevertheless, it must be considered that the social environment is dynamic and adapts to change. The focus should be on the active management of social impacts than on the prediction and once-off mitigation thereof. Successful mitigation and management of social impacts requires long-term commitment and involvement and should form part of the strategic planning and management of the project until decommissioning. Suggestions for the management of social impacts are included in the report in the form of a social impact management plan (SIMP). The implementation of the relevant management suggestions should start as soon as possible since the social impacts of the project started when the project was announced. Another important consideration in this project is the social context in which it will be executed. Impacts are assessed from a community perspective, and where it will influence a specific group of stakeholders it will be indicated as such. An attempt was made to simplify the impact assessment and to focus on aspects that can aid the decision-making process.

Social impacts are the result of social change, and to fully understand the potential impacts it is important to know the impact pathways. A social change process is a discreet, observable, and describable process that changes the characteristics of a society, taking place regardless of the societal context (that is, independent of specific groups, religions etc.). Social change processes can be measured objectively. The way in which social change processes are perceived, given meaning, or valued, depend on the social context in which various societal groups act. Some groups in society are able to adapt quickly and exploit the opportunities of a new situation. Others (e.g. vulnerable groups) are less able to adapt, and will bear most of the negative

5103

consequences of change. These social change processes may, in certain circumstances and depending on the context, lead to the experience of social impacts. Social impacts are therefore completely context dependent (Vanclay, 2003).

8.2 Impact assessment criteria

It must be stated that the impact tables and ratings were adapted from the environmental sciences and that it is not always possible to compartmentalise the social impacts. For the sake of consistency this has been attempted, but it is not innate to social sciences. Allowance for the changing and adaptive nature of social impacts should be made when interpreting the impact tables.

The rating criteria used in determining the significance ratings are summarised in the tables below:

Figure 23: Criteria for determination of impact consequence.

Aspect	Score	Definition
Nature	- 1	Likely to result in a negative/ detrimental impact
	+1	Likely to result in a positive/ beneficial impact
Extent	1	Activity (i.e. limited to the area applicable to the specific activity)
	2	Site (i.e. within the development property boundary),
	3	Local (i.e. the area within 5 km of the site),
	4	Regional (i.e. extends between 5 and 50 km from the site
	5	Provincial / National (i.e. extends beyond 50 km from the site)
Duration	1	Immediate (<1 year)
	2	Short term (1-5 years),
	3	Medium term (6-15 years),
	4	Long term (the impact will cease after the operational life span of the project),
	5	Permanent (no mitigation measure of natural process will reduce the impact after construction).
Magnitude/ Intensity	1	Minor (where the impact affects the environment in such a way that natural, cultural and social functions and processes are not affected),
	2	Low (where the impact affects the environment in such a way that natural, cultural and social functions and processes are slightly affected),
	3	Moderate (where the affected environment is altered but natural, cultural and social functions and processes continue albeit in a modified way),
	4	High (where natural, cultural or social functions or processes are altered to the extent that it will temporarily cease), or

1899

	5	Very high / don't know (where natural, cultural or social functions or processes are altered to the extent that it will permanently cease).
Reversibility	1	Impact is reversible without any time and cost.
	2	Impact is reversible without incurring significant time and cost.
	3	Impact is reversible only by incurring significant time and cost.
	4	Impact is reversible only by incurring prohibitively high time and cost.
	5	Irreversible impact

Figure 24: Probability scoring.

Aspect	Score	Definition
	1	Improbable (the possibility of the impact materialising is very low as a result of design, historic experience, or implementation of adequate corrective actions; <25%).
	2	Low probability (there is a possibility that the impact will occur; >25% and <50%),
	3	Medium probability (the impact may occur; >50% and <75%),
	4	High probability (it is most likely that the impact will occur- > 75% probability), or
	5	Definite (the impact will occur),

Figure 25: Criteria for the determination of prioritisation.

Aspect	Score	Definition
Cumulative impact (CI)	Low (1)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is unlikely that the impact will result in spatial and temporal cumulative change.
	Medium (2)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is probable that the impact will result in spatial and temporal cumulative change.
	High (3)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/definite that the impact will result in spatial and temporal cumulative change.
Irreplaceable loss of resources (IR)	Low (1)	Where the impact is unlikely to result in irreplaceable loss of resources.
	Medium (2)	Where the impact may result in the irreplaceable loss (cannot be replaced or substituted) of resources but the value (services and/or functions) of these resources is limited.
	High (3)	Where the impact may result in the irreplaceable loss of resources of high value (services and/or functions).
Degree of Confidence	Low	<30% certain of impact prediction
	Medium	>30% and <60% certain of impact prediction
	High	>60% certain of impact prediction

8.3 Social impacts and mitigation

In this section each impact will be described. The project will not have a construction phase and the mitigation measures for each impact that are relevant will be discussed at the end of the section.

8.3.1 Uncertainty

The fishing communities are uncertain about the impact that the seismic survey will have on their livelihoods. They feel that there is not enough information available to them to determine whether the surveys will have an impact on their activities. In the past year a number of companies approached them to participate in EIA processes about seismic surveys. They want to have some definitive answers about the potential impacts from specialists. They would like to engage with them for more than two hours to make sure that they understand exactly what the project entails and what the potential impacts are. Only then will they be able to make informed decisions. The fishing communities have made a living from the sea for hundreds of years and they have learned how to read the ocean and the weather to know where and when fish are moving. They are concerned that the surveys could disrupt the behaviour of snoek (that is endemic to the area and a major source of income) and other fish that they rely on. They have noticed changes in the patterns of the fish they catch due to industrial activities in the past. Some examples are the potato factory in Lambert's Bay that discharges warm water in the sea and the coffer dams constructed by the diamond mines. After a previous seismic survey at the Wild Coast, people observed dead Black Steenbras that were reported to have protruding nostrils. Furthermore, they also noticed changes in the patterns of the fish that they ascribed to climate change. For the fishing communities, the sea is an integral part of their identity, and they possess local knowledge that are not yet written up in scientific reports.

The marine fauna and fisheries reports indicate that low to negligible impacts on marine life and that all the impacts are reversible. However, the communities are not convinced. According to them, the fish can either go deeper in the sea to get away of the source of noise, which would be a tragedy for them, or they can go closer to the

shore, which would be beneficial for them. They feel that no-one can predict with certainty how the fish would respond to the noise, just that they would try to move away from the source.

The impact of seismic surveys on the catchability of marine fish remains a contentious issue for communities, with some claims that seismic surveys may negatively affect catch rates. However, little empirical evidence exists to quantify the impact or identify the mechanisms of such impact. The communities feel that there is simply not sufficient data available to negate or substantiate these claims and much more research on the topic is needed, especially from a local perspective. The consensus seems to be that there is a great knowledge gap in this regard. Community members feel that companies doing seismic surveys or those who have an interest in the data obtained through seismic surveys can make a great contribution to scientific knowledge of this field by funding independent research on the topic in South African waters.

People's livelihoods are already impacted by external factors such as fishing quotas, climate change, commercial over-fishing, mining in the sea and the recent Covid pandemic. They fear that the seismic surveys will contribute to an already dire situation and be a tipping point that will render them helpless and without their last source of income. They see seismic surveys as a gateway to oil and gas exploration and are concerned about the potential impacts that the results of the seismic surveys can unlock. There is a high level of uncertainty about the future of the ocean, which causes great concern and distress amongst the fishing communities, especially because the uncertainty is related to their livelihoods, and they are already struggling to make ends meet. Uncertainty also takes its toll on people psychologically and may result in mental health issues for some people in the long run.

8.3.2 Further marginalisation of vulnerable groups

In South Africa, claims for and access to natural resources are deeply embedded in people's histories, identities, and livelihood experiences. As in the case of land, access to and rights over fisheries resources is a highly contested issue where individuals and communities have equated such rights with human rights (Williams,2021).

Globally, fishing activities for many communities sees strong cultural and traditional links spanning many generations, and its value is seen beyond the means of earning a living (i.e. economic values). Whilst fishing takes place at sea, other activities related to fishing such as boat and net maintenance, the selling and trading of fish, etc. take place on land. Men and women are involved in fishing and indigenous knowledge and skills such as gutting and cleaning fish, reading the sea, and finding fish are transferred from generation to generation. The activities associated with fishing create a particular identity or characterise an area as a result of these activities (Williams,2021). Fishing is part of the cultural identity of the people living in fishing villages on the West Coast.

Many of the people on the West Coast belong to the Nama, Khoi or San people. Most of the Khoi people were traditionally cattle or sheep herders, while the San people were traditionally hunters and gatherers (www.san.org). They were the first inhabitants of southern Africa and one of the earliest distinct groups of homo sapiens. They have endured centuries of gradual dispossession at the hands of waves of new settlers, including the Bantu, whose descendants make up most of the black population of South Africa (https://foreignpolicy.com/2018/10/19/south-africas-first-nations-have-been-forgotten-apartheid-khoisan-indigenous-rights-land-reform/).
The process of land distribution instituted by the Government since 1994 has largely excluded the Khoi and the San people, as the government has not acknowledged them as the country's first peoples and their land was mostly taken before the apartheid era. There is a growing movement of indigenous activists that believe it is time to rightfully claim their traditional land.

One of the Khoi and San's biggest challenges is the racial classification system used in South Africa. They are being classified as 'Coloured' - a label that was used during Apartheid for citizens that did not fit the binary race model and included mixed-race children and Afrikaans-speaking non-whites. This categorisation condemned much of the Khoi and San's history to oblivion and facilitated the appropriation of their land. It excluded them from land restitution as it was conceived to be a benefit to black South Africans, and they were not considered to be black. As such the Khoi and San are

5623

considered to be very vulnerable and marginalised groups. Being marginalised means that they may easily be overlooked by corporate groups or businesses unfamiliar with the local history. Their needs, their views and even themselves as a stakeholder group can easily be omitted – both intentionally and unintentionally. In Searcher's previous application for a seismic survey in the area the Khoi and San felt that they were not consulted with. Therefore, they are sceptic about Searcher's intentions. They felt that they were discriminated against by not being consulted during the previous application, deepening their status as marginalised groups, and causing distraught to them as groups. Many of the fishers are of Khoi and San descendance, and they feel that they simply cannot win in any situation – whether it is fishing rights, land rights or culture identity.

With increasing interest in the West Coast area by seismic surveyors, which is viewed as the precursor for oil and gas companies to start developing the area, these communities risk increased marginalisation and an increase in vulnerability with every application where their voices are not being heard. They feel that currently they need to fight to make their voices heard. They have been using legal avenues, as they feel that just speaking up is not effective and has failed to give them the desired outcomes. Communities feel that their cultural heritage is threatened.

The San has published the San Code of Research Ethics that provides a guideline for researchers and companies that want to work in their sphere of influence on how to conduct themselves and how to interact with the San. From their perspective, an EIA application is also viewed as a form of research. This guideline can be applied to the Khoi and other people in the fishing communities as well. The San Code of Research Ethics is based on:

- Respect for individuals, community and culture;
- Honesty;
- Justice and fairness;
- Care; and
- Process (following San research protocol).

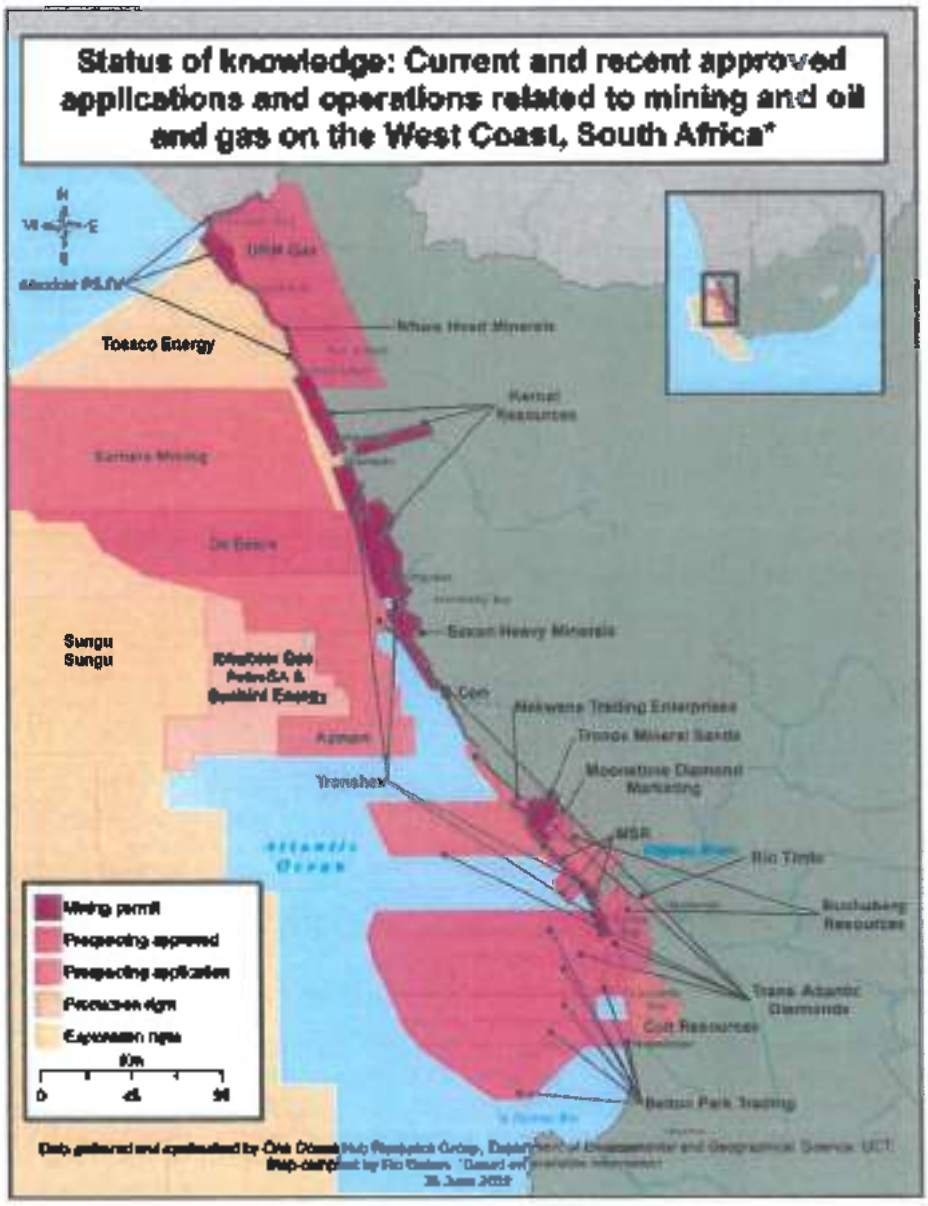
5628

The San Code of Research Ethics states that lack of care can be demonstrated by talking down to communities, confusing them with complicated scientific language, or treating communities as ignorant. It further states that a lack of care is also represented by failing to ensure that something is left behind that improves the live of the San.

8.3.3 Concerns about cumulative impacts

A great source of concern for the fishing communities is the effect of cumulative impacts on their livelihoods and sense and spirit of place. There are a number of applications in process as well as approved applications relating to seismic surveys, mining, and oil and gas exploration in the West Coast area. There are also existing mining activities, significant shipping traffic and commercial fishing taking place in the ocean. The concern is that at some stage a tipping point will be reach where the marine life no longer recovers from the activities in the ocean or take a long time to recover to the extent that it would no longer be viable to make a living from the sea in those areas. In Norway small-scale fishing successfully co-exists with oil extraction in the ocean, but for the small-scale fishers on the West Coast, it remains uncertain to what extent it will be the case for them as well. Although cumulative impacts are assessed as part of the EIA process, there are limitations associated with budgets, timeframes, and access to resources. The competent authorities have a legal and moral duty to consider the cumulative impacts of the activities taking place and are planned to take place on the livelihoods and heritage of the vulnerable communities in the area from a strategic perspective. There must be a balance between the contribution these activities can make to South Africa's economy and sustaining the livelihoods of the vulnerable communities on the West Coast. The communities are clear that they do not necessarily want to stop development, they want to make sure that their livelihoods and heritage are protected, and that the rights of future generations will not be compromised. Once these have been affected negatively, it may not be possible to easily undo the damage.

Figure 26: Current and recently approved applications and operations relating to mining, oil and gas.



8.3.4 Impact on livelihoods

A livelihood refers to the way of life of a person or household and how they make a living, in particular, how they secure the basic necessities of life, e.g., their food, water, shelter and clothing, and live in the community (Vanclay et al., 2015). The coastal communities in the area of interest are mostly fishing communities that make their livelihoods from the sea and have been doing so for generations. They rely on the ocean for food and economic security, as well as their identity and heritage. They

know how to make a living from the sea. If it is no longer possible for them to make a living from the sea, or if their ability to make a living from the sea is reduced it will result in a great increase in poverty in the area as there are very limited alternative options for them to make a livelihood. Their skill sets are strongly linked to the sea and cannot be transferred to other economic activities without skills development, training activities and the economic diversification of the area. Men and women rely on the sea for their livelihoods, and it is closely linked to the culture and identity of the people. This makes these communities extremely vulnerable. Furthermore, an increase in poverty in the area will place an additional burden on tax payers.

The small-scale fishers can travel approximately 15 nautical miles offshore with their boats. Some of them have indicated that they already sometimes need to go further to be able to catch enough fish, which is not only more expensive for them in terms of the diesel required for their boats, but it is also more dangerous. In the mining areas around Port Nolloth they are struggling to get access to the sea and the areas where they are allowed to fish are getting smaller.

Livelihoods are already compromised due to the fishing quota system, over-fishing, lack of employment opportunities, pollution, effects of climate change and the recent Covid 19 pandemic.

8.3.5 Impacts on sense and spirit of place

Sense of place refers to an individual's personal relationship with his/her local environment, both social and natural, which the individual experiences in his/her everyday daily life (Vanclay et al, 2015). It is highly personal, and once it is affected, it cannot be restored. It is also difficult to quantify. The environmental philosopher Glenn Albrecht noted a consistent theme of distress caused by coal mining in Australia by the assault on the people's sense of identity, place, belonging, control, and good health. He identified a melancholia from the loss of solace and comfort connected with their home which he termed 'solastalgia' – a form of homesickness that one gets when one is still at 'home' associated with the major project impacts they experienced (Albrecht et al, 2007). Social impacts can therefore range from significant health impacts to the loss of a cherished landscape and associated loss of a sense of place.

Spirit of place refers to the unique, distinctive, and cherished aspects of a place. Whereas 'sense of place' is the personal feelings an individual has about a place, spirit of place refers the inherent characteristics of the place (Vanclay et al, 2015). In this case the spirit of place includes the ocean and the properties assigned to it.

Many things can impact on a person's perception of sense of place. For the fishing communities the ocean is an integral part of their being, therefore anything that is perceived to potentially harm the ocean would also cause harm to them. The ocean provides them with food and thus keeping them from starvation. For many the sea is a sacred place. Its water has healing powers that take care of the sick. Many loved ones have given their lives to the ocean while they were out trying to make a living, and their remains have never been found. The sea kept their bones, making the ocean the graveyard where their loved one's rest. For some people the thought of disturbance in the sea causes great distress. The heritage aspects relating to this are discussed in the heritage impact assessment report. Although this cultural and spiritual connection with the sea might be difficult to understand for outsiders, it must be respected as a cultural right.

8.3.6 Impacts on the social licence to operate

Social licence to operate (SLO) is a popular expression to imply that the acceptance of the community is also necessary for a project to be successful. It appears as if Searcher does not currently have social licence to operate in the fishing communities. Based on the events surrounding Searcher's previous application and recent reports about seismic surveys in the media, the communities expressed that they do not trust Searcher or any other company conducting seismic surveys. Applications for seismic surveys and community opposition to these surveys have been widely reported and debated in the media during the last year (Compare News 24, 13 Jan 2022; Mail and Guardian, 20 Jan 2022; Eye Witness News, 1 September 2022 amongst others). Numerous NGOs specialising in social and environmental justice have aligned with communities and assist them with opposing seismic surveys. Some community members think that seismic surveys are opening the door for oil and gas exploration,

which is a great concern for them, mostly due to the anticipated impacts on their livelihoods.

Given that there are a number of applications for seismic surveys in the Orange Basin, and that each application is subjected to a Basic Assessment process, communities are confused and reaching saturation regarding consultation. From their perspective, with each new application, it is a new face standing in front of them, from a new company, but "basically everyone wants the same thing". Communities do not distinguish between different seismic survey companies. They feel as if their questions are not answered, and concerns are not addressed – each consulting firm just repeat the same technical information about what a seismic survey entails to them. Although this is not Searcher's fault and they are following a prescribed legal process, it impacts on their social licence to operate and on the seismic survey industry as a whole.

The term "social fabric" embraces numerous complex and interrelated phenomena, including demographic and economic factors, behavioural issues (e.g. investment choices, political dynamics), social institutions (e.g. families), social organisations (e.g. municipalities and churches), and social networks, or relationships amongst people. The social fabric is underpinned by people's beliefs and sentiments, including a sense of belonging and identification with a particular social unit (Atkinson et al, 2017).

The social fabric in the communities have been damaged through previous negative experiences with businesses in the area. A number of factories in the greater area have closed or moved away and in the process of doing so created great hardship for the communities remaining behind. Very little severance was paid, and this aggravated the communities. Mines closed without proper rehabilitation plans. In some places, access to the areas where they earn their livelihoods are becoming increasingly restricted, especially through the activities of mining companies. This has reached a point where the communities have realised that they need to fight for the protection of their livelihoods as historically companies have in most cases not treated them fairly or with respect. It is unlikely that any company that would like to undertake an activity in the ocean will be given social licence to operate by the community. The community have been traumatised by historical events and behaviour of companies

BLDS

too many times. On the other hand, there are members in the community that welcome any new development and feel that living from the sea has its limitations and would soon be impossible. The dynamics between the different groups in the community, caused by the myriad of seismic survey applications, has already done significant harm to the social fabric of the fishing communities. People with individual agendas cause conflict in the community, and given the vulnerability of the community, the dire socio-economic conditions and high levels of poverty, illiteracy and unemployment, community members are susceptible to these forms of manipulation.

> ***Example of deterioration of social fabric:***
>
> *An individual rallied the youth in the community by telling them that they will be given work by Searcher (specifically) and ask them to complete forms and sign it. Searcher is unaware of this activity. Other members of the community find out about this and informed the consultants. Older community members fear that the signatures will be used to show community support to the project. Community members that lived together in peace and harmony for years are suddenly not talking to each other, and the community is divided.*

Another aspect that affects Searcher's current social license to operate negatively, is that they failed to conduct sufficient meaningful consultation with the small-scale fishers in the past. The MPRDA Regulations as amended in 2020 define meaningful consultation as: *consulting in good faith, in a way that gives the landowner, lawful occupier and/or interested and affected persons all the relevant information, and reasonable time and opportunity to make an informed decision regarding the impact of the proposed activities.*

The communities feel disrespected and marginalised by the processes followed up to date by Searcher and other companies. Engaging with the communities in a meaningful way, following the appropriate structures and protocols, will go a long way in improving Searcher's social license to operate. It does not guarantee that the communities will accept Searcher or any other company wanting to conduct seismic surveys. It must be kept in mind that improving social license to operate takes time and effort.

8.3.7 Community expectations

Not everyone in the fishing communities is opposed to the project or to oil and gas exploration. Their perceptions are that the ability to make a living from the sea is already declining. It is a hard live and they want a better life for their children. There are very limited alternative opportunities for making a livelihood and very limited job opportunities. They will support industrial development in the area if it brings opportunities for their children for employment and skills development. They want to know that they will benefit from the process that will be set in motion by the seismic surveys. They know they will not be direct beneficiaries from the extraction of oil and gas, but that they will be the ones that pay the price. Their expectations are that the oil and gas companies will invest in these communities and assist them with creating alternative livelihoods and obtaining the necessary skills and experience in that regard. Although Searcher will be doing a survey to gather data that will be utilised by oil and gas companies, and Searcher's activities will be of a temporary nature, with little benefit to the locals, the communities do not distinguish between data collection and exploration or extraction. For them these companies are one and the same, and they have similar expectations of Searcher.

The proposed project collects data that would be of great value for the companies interested in extracting oil and gas in the area in future. Should this happen, it would have a positive impact on the economy of South Africa, seen together with the Government's plans for the development of a new industrial port at Boegoebaai. In a country with very high unemployment levels and suffering from a recession and an energy crisis, this is seen as a positive future development by many role players. As such, the communities feel that the government supports the application, and that community consultation is simply a matter of ticking the boxes. The question of who pays the price and who gets the benefit is relevant in this context. The price that the fishing communities will pay eventually, will be high as it may have an extremely negative impact on their livelihoods with little or no benefit to them, unless measures are put in place to protect their livelihoods. It must be considered that community livelihoods are broader than just catch rates and fishing, but includes the capabilities,

assets (including both material and social resources) and activities required for a means of living.

8.3.8 Social unrest

Generally, social unrest occurs when a group gathers publicly to express dissatisfaction or anger centred around a common cause and is usually accompanied by a demand for societal change. Poor socio-economic conditions caused by unemployment rates, corruption, inflation, and bad governance can contribute to social unrest. South Africa has a history of using protests to air grievances. Social unrest is often triggered by an event or action that provokes strong feelings amongst community members.

Some of the communities are adamant that they would not allow gas or oil extraction in the area, and that includes collecting the required data from the ocean. There have already been court cases in this regard, and there are also court cases that are ongoing. Some community members have threatened with violence against Searcher's vessel. Others have threatened that they will take action to fight seismic surveys, in any way that they seem appropriate. This is a very emotional issue for many people and that could erupt into social unrest. Related to this is potential for conflict between community members who support the project and those that are against the project.

8.3.9 Mitigation and management

Searcher's activities for this application would be of short duration if approved, and if viewed in isolation considering only technical risks as discussed in various specialist reports conducted as part of the EIA process, the impacts will be negligible. However, communities feel that there are significant gaps in the available data and from a social perspective the non-technical or social risks can potentially cause significant impacts. Although the marine fauna and fisheries specialists have indicated that the impacts on the marine fauna would be negligible, the communities, with generations of experience in the ocean, fear that the behaviour of the fish will change and that this would affect their catch rates and consequently their livelihoods. What is seen as a minor impact in a large eco-system may be experienced as a major impact by an individual. The marine fauna might not be affected greatly, but the fishing community

fear that marine fauna might change its behaviour in response and that is a main concern from a social perspective.

It must be considered that from a social perspective perceived impacts (something that is believed to be a potential impact rather than something that has been established as being an actual impact) should be treated as real impacts. Perceived impacts affect how people feel about the project and how they feel and behave generally, thus perception is reality for them (Vanclay et al, 2015). While the public's assessment of risk is perceptual in nature, their fears should not be dismissed as irrational and therefore unimportant. Living with the fear and uncertainty is an impact in itself (Burdge, 1998).

There are current impacts on the livelihoods of the communities from aspects such as pollution, shipping traffic, mining in the sea, over fishing and climate change. The cumulative impact of additional activities in the ocean where these communities earn their livelihoods is of concern to them, especially if a number of companies engage in exploration activities in the area in an unplanned manner. They urge the government to approach the matter from a strategic perspective. The strategic approach is not the responsibility of Searcher but must be managed by government.

The short-term nature of the seismic reconnaissance and proximity from communities must be considered when suggesting mitigation measures. The mitigation measures suggested must be seen as building blocks for any potential further developments or activities that may be conducted by Searcher in future.

Figure 27: **Potential mitigation for impacts on existing livelihoods.**

No	Mitigation Measures	Phase	Timeframe	Responsible party for implementation	Monitoring party (frequency)	Target	Performance indicators (monitoring tool)
1	Searcher should develop a community engagement protocol that is based on the San Code of Research Ethics. This should be done in consultation with the affected communities and include a communication strategy and grievance mechanism.	All phases	Commence in the planning phase and continue throughout the life of the project	Searcher	Keep records of all communication with communities throughout the life of the project	Establish good relationships with fishing communities	Written community engagement protocol Communication register, social risk and incident register
2	Searcher should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as shoek respond to seismic surveying. Collaboration across seismic operators with holders of hydrocarbon exploration and the industry as a whole to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study. This would quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in South African Waters.Communities should be consulted on the issues that should be researched.	All phases	Commence in the planning phase and continue throughout the life of the project	Searcher	Meetings with communities. Meetings with independent research organisations	Protect the livelihoods of the fishing communities	Minutes of meetings Written agreements with independent research organisations such as universities

1914

3	Consult with communities on ways in which to positively contribute to the communities.	All phases	Commence in the planning phase and continue throughout the life of the project	Searcher	Meetings with communities	To give something back to the communities	Minutes of meetings Written agreements with candidates
4	A representative from Searcher should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist with readjusting the relationship between Searcher and the traditional communities. If needed, the meetings can be facilitated by an external party. This is an explicit request from community members and failing to do so will increase the reputational risk for Searcher and weakens their social licence to operate further. It will also cause significant delays in the application process. Given the current socio-political conditions in the coastal communities following prescribed legal processes is not sufficient to be seen as meaningful consultation from a community perspective.	All phases	Commence in the planning phase and continue throughout the life of the project	Searcher	Meetings with leadership	To ensure that there will be no misunderstanding about what meaningful consultation entails in future. It will also assist with clearing up past misapprehensions	Minutes of meetings

1915

5	Assessing all cumulative impacts of the seismic survey industry on the livelihoods of communities, addressing perceptions and alleviating fear from a strategic perspective is not Searchers' responsibility and falls outside the scope of one environmental impact assessment. It is the responsibility of the relevant authorities and the industry. However, the seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign. Having meetings will not be sufficient. Participatory processes and workshops where communities can engage in experiential learning should be considered. If the seismic survey industry fails to address the community's need for education and cooperation it will result in significant delays and increase the risk for social unrest.	Before the study commence	Before the study commence	Searcher to initiate discussions with the industry governing bodies.	Meetings with industry role players and relevant authorities	Ensure that communities can make informed decisions and engage in meaningful conversations about seismic surveys.	Workshops, awareness raising campaigns and community education

9 Conclusion and recommendations

Searcher's activities for this application would be of short duration if approved, and if viewed in isolation considering only technical risks as discussed in various specialist reports conducted as part of the EIA process, the impacts will be negligible. However, communities feel that there are significant gaps in the available data and from a social perspective the non-technical or social risks can potentially cause significant impacts. Although the marine fauna and fisheries specialists have indicated that the impacts on the marine fauna would be negligible, the communities, with generations of experience in the ocean, fear that the behaviour of the fish will change and that this would affect their catch rates and consequently their livelihoods. What is seen as a minor impact in a large eco-system may be experienced as a major impact by an individual. The marine fauna might not be affected greatly, but the fishing community fear that marine fauna might change its behaviour in response and that is a main concern from a social perspective.

Another concern is the cumulative impact of activities in the ocean where these communities earn their livelihoods. Their fears about the tipping point where their source of livelihood does not recover from all the activities in the ocean, and they are no longer able to make their livelihood as fishing communities must be considered. Currently these communities are able to sustain themselves, although it is difficult. The communities are not against development, but they want to see it happen in a sustainable way that does not jeopardise their source of livelihood. They have already seen how their livelihoods are being affected by mining that is taking place in the sea, pollution, climate change, over fishing and businesses such as factories that come and go and often and do not leave in a socially responsible way.

Searcher, as well as other companies that want to do surveys or exploration in the area, currently do not have social license to operate. A large part of this is due to a lack of meaningful consultation from a community perspective. If Searcher or any other seismic survey company wants to proceed with the project, they will need to

1908

engage in meaningful conversation with the communities and try to restore relationships. From a community and social risk perspective this is not negotiable.

Seismic reconnaissance projects are controversial in South Africa and has been in the news frequently in the last year. For many stakeholders it is an emotional matter, for others the potential of impacting their livelihoods is the biggest fear. There are also stakeholders that feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change. Other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. It is a complex and wicked[2] problem.

Based on the findings, the following recommendations are made:

- Searcher should develop a community engagement protocol that is based on the San Code of Research Ethics. This should be done in consultation with the affected communities. This should include a communication strategy and grievance mechanism.

- Searcher should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. Collaboration across seismic operators with holders of hydrocarbon exploration and the industry as a whole to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study. This would quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in South African Waters.

- Consult with communities on potential ways in which to make a positive contribution to the communities.

- A representative from Searcher should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist

[2] a wicked problem is a problem that is difficult or impossible to solve because of incomplete, contradictory, and changing requirements that are often difficult to recognize.

5608

with readjusting the relationship between Searcher and the traditional communities. Given the socio-political environment, opposition to the project and associated non-technical risks, further meaningful engagement with the leadership and communities are critical from a social perspective.

- Searcher should initiate discussions in their industry. The seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign. Having meetings will not be sufficient. Participatory processes and workshops where communities can engage in experiential learning should be considered. If the seismic survey industry fails to address the community's need for education and cooperation it will result in significant delays and increase the risk for social unrest.

From a social perspective it is clear that the communities and majority of local people are opposed to the project. If the project is considered in isolation, the impacts are negligible. However, the project does not happen in a vacuum, and the social environment is much wider than the footprint of the project. If the social risks and potential damage to cultural and indigenous rights are considered the impact on the social fabric of already vulnerable communities may be significant. From as social perspective the project can only be recommended after meaningful consultation, local research, education, and awareness raising has been done in the project affected communities. At this stage communities feel that they cannot make informed decisions. Although all legal processes have been followed, the seismic survey industry is not moving at the pace of the community, and in the long run this will be detrimental to the industry. Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed. The recommendation is therefore that the project can only proceed once the social mitigation measures have been implemented and the community are sufficiently informed and educated to able to engage in a meaningful manner.

Saldanha TGS interaksie

18 May 2023

"A11.5"

Ons as die vissers van Saldanha het n vergadering met EIMS by hoedtjies baai Hotel vir TGS bygewoon en ons het die volgende met hulle gedeel. Ons as visser is gekant teen alle forms van Olie en Gas in oseane vir die volgende redes. Die vis species wat tans folop is sal uitgeroei word en ons ervaring is dat hierdie vis spesies al reeds skaars as gevolg van klimaats verandering. Olie/Gas Drilling is n bedreiging vir alle marine spesies in die oseane. Dit gaan ons vissers voortbestaan verder in armoed dompel. Ons will dit pertunent stel van Noord tot Wes, Suid en Oos,ons is bank vas gekant teen Olie en Gas en ons weier om ons oseane beskikbaar te stell vir enige Olie en Gas. Hierdie vergadering was nie goed bygewoon die deur die bree gemeenskap nie en ons wonder was daar nog soort gelyke opvolg vergaderings gehou

Opvolg verslae:

Ons as die vissers, en Ek spesifiek wat by die vergadering was van TGS het geen terugvoering ontvang vanaf TGS tot kennisgewing 26 April 2023. Ons as Visser drae nie kennis van verslae wat in biblioteek of ander plekke was nie.Ons het nie geleenheid gehad om seker te maak dat ons komentaar well akuraat opgeteken was nie en dra nie kennis hoe hulle ons kometaar beantwoord het nie.

Baie Dankie

Carmerlita Mosterd

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
INTRODUCTION 1. This is an appeal to the Honourable Minister of Forestry, Fisheries and the Environment ("Appeal" to the "Minister"), directed to the Director: Appeals and Legal Review of the Department of Forestry, Fisheries and the Environment ("DFFE"), to set aside the decision of the Director-General of the Department of Mineral Resources and Energy (as "DG" or "DMRE") dated 17 April 2023 granting environmental authorisation to TGS Geophysical Company (UK) (as "Third Respondent") allowing for a 3D seismic survey off the West Coast of South Africa. 2. The Minister should set aside the decision to grant authorization because the Environmental Basic Assessment Report (FBAR) did not comply with NEMA in several ways. The decision to grant authorization violates various provisions of NEMA, including the requirements for granting environmental authorizations and the National Environmental Management Principles. The FBAR and the decision-maker failed to establish the need and desirability of the Project, failed to adequately consider marine impacts, and neglected to assess the cumulative impacts of the Project. The Second and Third Respondent also failed to engage in meaningful consultation, violating principles of fair administrative decision-making and the right of affected communities to be consulted. This failure to consult is inconsistent with NEMA's requirement to promote participation and take into account the interests of all parties. Moreover, the decision-maker disregarded NEMA Principles, including the precautionary principle and the principle of sustainable development, as well as the constitutional right to a non-harmful environment. The decision therefore to issue the authorization and the reasons provided are deemed irrational and unreasonable. 3. The Appellant submit this appeal on the following grounds:	For the reasons provided in the responses below it is the opinion of TGS Geophysical Company (UK) (TGS) that the Environmental Authorisation (EA) should remain valid, since the Basic Assessment Process was conducted in line with the requirements of the Environmental Impact Assessment (EIA) Regulations, 2014, as amended. This included amongst others that: • The Need and Desirability of the Project was adequately addressed and assessed – Refer to Section 5 of the Basic Assessment Report (BAR)); • Marine and cumulative impacts were considered in detail in the BAR – refer to Section 9 of the BAR; • The EAP appointed for the project conducted an extensive Public Consultation Process, which resulted in meaningful consultation – Refer to Section 7 and Appendix 2 of the BAR; • As stated in Section 11.3 of the BAR, The findings of the specialist studies conclude that there are no environmental fatal flaws that should prevent the proposed project from proceeding, provided that the recommended mitigation and management measures are implemented. Based on the nature and extent of the proposed project, the local level of disturbance predicted as a result of the reconnaissance activities, the findings of the specialist studies, and the understanding of the significance level of potential environmental impacts, it is the opinion of the EIA project team and the EAP that the significance levels of the majority of identified negative impacts can generally be reduced to an acceptable level by implementing the recommended mitigation measures and the project should be authorized.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
3.3. Ground 3: Failure to adequately assess cumulative impacts 3.4. Ground 4: Failure to conduct meaningful consultation with communities and local people (and in particular small-scale fishers), within the public participation process, including the Social Impact Assessment process. 3.5. Ground 5: The FBAR does not contain a proper and objective assessment of the negative impacts of the project on people's human rights 3.6. Ground 6: Failure to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008 3.7. Ground 7: Failure to provide adequate reasons for the decision 4. The Authorisation, with reference number 12/1/040, was granted in terms of regulation 24 of the National Environmental Management Act, 1998 ("NEMA") Environmental Impact Assessment Regulations, 2014 ("EIA Regulations"). 5. The Appeal is lodged in terms of section 43(1A) of NEMA, which provides that: "*Any person may appeal to the Minister against a decision made in terms of this Act or any specific environmental management Act by the Minister responsible for mineral resources or any person acting under his or her delegated authority*", read with the NEMA National Appeal Regulations, 2014[1] ("the Appeal Regulations"), which provide for the submission of an appeal within 20 days from the date that the notification of the decision for an application for environmental authorisation was sent to the registered interested and affected parties (I&APs) by the Applicant (26 April 2023).[2]

1931

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
6. In accordance with the requirements of Regulation 4(2)(a) of the Appeal Regulations: 6.1. this Appeal is submitted in writing in the form obtained from the Appeal Administrator, and accompanied by this more detailed appeal document, being a statement setting out the grounds of appeal ("the Grounds of Appeal"). The Appellants are entitled to also submit these more detailed Grounds of Appeal as the Appeal submission. This submission must be taken into account by the Minister in making a decision on the Appeal; 6.2. to the extent possible, the Appeal is accompanied by relevant supporting documentation which is referred to in this Appeal submission - attached as Annexure B; and 6.3. we confirm, in compliance with Regulation 4(1) of the Appeal Regulations, that this Appeal is submitted within 20 days[5] from the date of notification to I&APs to the Appeal Administrator. A copy of the Appeal will be provided to the Applicant and to those registered I&APs, and organs of state with an interest in the matter, insofar as possible and within time and cost constraints. The statement regarding compliance with Regulation 4(1) is contained in the cover letter to which these Grounds of Appeal are attached. In any event, we confirm compliance with Regulation 4(1). 7. The Appellants further submit that there are grounds for judicial review under the Promotion of Administrative Justice Act, 2000 ("PAJA") because the Authorisation comprises administrative action that *inter alia*.		

[5] The Appellants submit that the process provided for in the Appeal Regulations, in particular the requirement to submit an appeal in 20 days of the notification, severely prejudices the Appellants and infringes on their rights to a fair process. The Appellants continue to assert that the unreasonably short timeframes and onerous notification requirements of regulation 4(1), among others, render the Appeal Regulations a violation of the rights to just administrative action, and are thus unconstitutional.

Initial/s

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
7.1. is unconstitutional or unlawful;[4] 7.2. was taken because of the failure to consider relevant considerations;[5] 7.3. is not rationally connected to the information before the decision-maker in making the Decision or to the reasons provided by the decision-maker for the Decision;[6] and 7.4. is so unreasonable that no reasonable person could have granted it.[7] **PARTIES** 8. The First Appellant is **Natural Justice**. 8.1. Natural Justice: Lawyers for Communities and the Environment is a non-profit organization specializing in environmental and human rights law in Africa – with a focus on the pursuit of social and environmental justice for local and indigenous communities. Natural Justice offers direct support to local and indigenous communities impacted by the ever-increasing demand for land and natural resources.. 9. The Second Appellant is **the Green Connection.** 9.1. Green Connection is a registered non-governmental organisation, that believes that economic growth and development, improvement of socio-economic status and conservation of natural resources can only take place within a commonly understood framework of sustainable development. The Green Connection aims to provide practical support to both		

[4] PAJA section 6(2)(d),(f)(i) and (ii).

the government and non-governmental/civil society sectors, which are an integral part of sustainable development. 10. The Appellants have legal standing to bring the Appeal not only in terms of section 43 of NEMA, but also to enforce environmental laws in terms of NEMA section 32, in that they *inter alia* act: *"(c) in the interest of or on behalf of a group or class of persons whose interests are affected; (d) in the public interest; and (e) in the interest of protecting the environment."*[8] The Appellants act in the interest of, or on behalf of, persons who, for practical reasons, are unable to institute such proceedings, including members of coastal communities who do not have the capacity or resources to do so, in the interests of coastal communities who are affected by the proposed seismic activities, in the public interest, and in the interest of protecting the environment, to further the objectives of section 24 of the Constitution of the Republic of South Africa, 1996 ("the Constitution") and NEMA. 11. The Appellants are also Registered Interested and Affected parties (I&AP) in respect of the application process for this authorisation. **BACKGROUND AND DESCRIPTION OF THE PROJECT** 12. The proposed project area is located between approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay over a number of petroleum licence blocks. The application area for the proposed 3D seismic survey is approximately 57 400 km^2 in extent. TGS proposes that a single survey vessel equipped with seismic sources and streamers be used. The proposed 3D survey would be supported by two escort vessels. It is estimated that the 3D survey will take 70 days (including downtime).[9] The area proposed for the

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
seismic survey is a large under-explored area with potential for both oil and gas. 13. On the 25th of November 2022, the Applicants submitted comments on the draft Basic Assessment Report prepared as part of the Environmental Impact Assessment (EIA) process. As mentioned above, the DG granted the Project an Environmental Authorisation on 17 April 2023, and the Appellants received notification of the decision on 26 April 2022. 14. The Reasons for the Decision are set out in Annexure 1 to the Authorisation. GROUNDS OF APPEAL 15. The decision to grant the Authorisation should be set aside by the Minister because the final Environmental Basic Assessment Report ("FBAR") failed to comply with NEMA in various respects; and the Director General's decision to grant the Authorisation contravenes various provisions of NEMA, including the requirements for granting environmental authorisations, the requirements of the National Environmental Management Act and the National Environmental Management Principles (section 2 of NEMA) ("NEMA Principles"), in that: 15.1. the need and desirability of the Project has not been established, as required by regulation 18 of the EIA Regulations read with regulation 23(3) and Appendix 3 to the EIA Regulations. 15.2. the FBAR and the DG failed to adequately consider the marine impacts and therefore have failed to meet the requirements of, inter alia, section 240(1) NEMA to account for all relevant factors,[10] in particular those regarding the pollution,		

[10] NEMA, section 2401(b).

Initials

1935

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
environmental impacts or environmental degradation *"likely to be caused if the application is approved"*,[11] as well as any guidelines, departmental policies, and environmental management instruments and any other information in the possession of the competent authority relevant to the Application.[12] This is also in contravention of the NEMA requirement to ensure that the activity's potential environmental impacts are properly assessed;[13] 15.3. The FBAR and DG have failed to adequately assess and consider the cumulative impacts of the Project, as required by the NEMA EIA Regulations, Appendix 3 section 3(j)(i). 15.4. TGS, and its appointed Environmental Assessment Practitioner ("EAP", has failed to engage in meaningful consultation in violation of the principles of fair administrative decision-making and the right of interested and affected communities to be meaningfully consulted prior to a decision on authorisation being made, and in violation of section 2(4)(f) of NEMA, which stipulates that the participation of all interested and affected parties in environmental governance must be promoted, and all people must have the opportunity to develop the understanding, skills and capacity necessary for achieving equitable and effective participation, and participation by vulnerable and disadvantaged persons must be ensured. It is also inconsistent with section 2(4)(g) of NEMA, which requires that decisions must take into account the interests, needs and values of all interested and affected parties, and this includes		

[11] NEMA, section 24O1(b)(i).
[12] NEMA, section 24O1(b)(viii).
[13] NEMA, section 24(4)(a)(iv).

Initial/s:

1936

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
recognising all forms of knowledge, including traditional and ordinary knowledge. 15.5. the DG failed to consider and/or give effect to: the NEMA Principles, including the precautionary principle and the principle that requires development to be environmentally, socially and economically sustainable; and the Constitutional rights to an environment that is not harmful to health or wellbeing – as enshrined in section 24 of the Constitution of the Republic of South Africa, 1996 ("the Constitution"). The decision to issue the Authorisation and the reasons provided therefore are, furthermore irrational and unreasonable, and thus in contravention of PAJA. 15.6. The DG failed to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008. 15.7. Ground 7: The DG failed to provide adequate reasons for the decision.		
Ground 1: A flawed and misguided need and desirability assessment 16. The NEMA EIA Regulations stipulate that a basic assessment report must include a motivation for the need and desirability for the proposed development, including the need and desirability of the activity in the context of the preferred location.[11] 17. Section 5 of the FBAR includes a motivation of need and desirability for the proposed 3D seismic survey. Unsurprisingly, the FBAR	The EAP has conducted the impact assessment on the basis of the activities proposed by the applicant. Any subsequent authorisation would be restricted to these specifically assessed activities. Should the applicant or other applicants wish to undertake any additional exploration activities which are not addressed in the current Environmental Authorisation (EA) application, there would be a consequent need to apply for the relevant permissions. These would include a formal application for an Exploration or Production Right as	

[11] NEMA EIA Regulations, Appendix 1, section 2(c). With regard to need and desirability, a distinction is drawn between the 'general purpose and requirements' of the proposed activity and 'need and desirability'. The 2017 Guideline on Need and Desirability states as follows (at p10):

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
focusses on justifying the 'need and desirability' of the proposed project and fails to reflect views critical to 3D seismic surveys and offshore oil and gas exploration (and ultimately production). As a consequence, the 'need and desirability' assessment provided in the FBAR follows the pattern of previous seismic survey EIAs by (among other things) limiting the assessment of potential impacts to the proposed 3D seismic survey, with no assessment of the need and desirability of exploring for (and ultimately producing and using) new oil and gas reserves (including in the context of the climate change crisis and the right to food). The assessment also includes a section motivating the 'need' for seismic data. 18. It is noted that the FBAR Needs and Desirability analysis indicates that the proposed project *'aims to identify oil and gas resources to be used in... energy production and/or processing or manufacturing of materials'*.[13] The FBAR also claims in passing that "seismic surveying is not only used for petroleum and natural gas exploration and development, it can in certain instances also be used for	well as a new EA. The impacts of such proposed activities would consequently require specific assessment and public consultation prior to approval. It is premature to assess the likely impacts of further invasive exploration activities or production activities as the extent, duration, location, and magnitude applicable to these activities are unknown at this stage. The NEMA EIA Regulations make a clear distinction between the reconnaissance, exploration, and production activities in that these are listed as distinct and separate listed activities. There is provision in law for these activities to be assessed on their merits as and when they are proposed. Please refer to Section 5 of the EA Report in regard to the need and desirability for the proposed activities. According to the Integrated Resource Plan 2019 (IRP 2019), which is the country's electricity planning strategy, there is a need for gas in South Africa's energy mix in the future. This need is driven in part by the expectation that natural gas may act as a transition fuel, whilst other greener technologies mature. According to the National Department of Forestry, Fisheries	

In order to properly interpret the EIA Regulations' requirement to consider "need and desirability", it is necessary to turn to the principles contained in NEMA, which serve as a guide for the interpretation, administration and implementation of NEMA and the EIA Regulations. With regard to the issue of "need", it is important to note that this "need" is not the same as the "general purpose and requirements" of the activity. While the "general purpose and requirements" of the activity might to some extent relate to the specific requirements, intentions and reasons that the applicant has for proposing the specific activity, the "need" relates to the interests and needs of the broader public.

...

The consideration of "need and desirability" in EIA decision-making therefore requires the consideration of the strategic context of the development proposal along with the broader societal needs and the public interest. The government decision-makers, together with the environmental assessment practitioners and planners, are therefore accountable to the public and must serve their social, economic and ecological needs equitably. Ultimately development must not exceed ecological limits in order to secure ecological integrity, while the proposed actions of individuals must be measured against the short-term and long-term public interest in order to promote justifiable social and economic development – i.e. ensuring the simultaneous achievement of the triple bottom-line. Considering the merits of a specific application in terms of the need and desirability considerations, it must be decided which alternatives represent the "most practicable environmental option", which in terms of the definition in NEMA and the purpose of the EIA Regulations are that option that provides the most benefit and causes the least damage to the environment as a whole, at a cost acceptable to society, in the long-term as well as in the short-term. (emphasis added)

The Guideline requires need and desirability assessments to address the impact of planned activities on global and international responsibilities relating to the environment, including climate change (at p11).

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
development of offshore wind, geothermal energy, and low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes." This statement about other uses is misguided and irrelevant. These other purposes of the projects surveying results are speculative at best, and have far less impacts on the ocean than oil and gas surveying.[16] It is also abundantly clear from the FBAR that the main purpose of this project is to survey for oil and gas deposits. 19. The FBAR concludes that *'[a]s a result of the fact that this project entails only survey activities, it is anticipated that this project will not lead to a significant impact on the receiving environment'.*[17] In line with this, the FBAR does not consider or assess the potential climate and other negative impacts of subsequent oil and gas exploration, production and use. In other words, it fails to consider the lifecycle impacts associated with exploring for and exploiting oil and gas resources. Yet, at the same time, it does consider the positive impacts should oil and gas be eventually produced, such as the claim that it will provide energy security to South Africa. This self-serving analysis is not only deceiving, it is unlawful. **Climate change impacts**	and the Environment (DFFE), targets have been determined to achieve our national GHG Emissions commitments. These targets consider the likely GHG emissions outcome of the implementation of current South African policies including the IRP. The proposed seismic activities may be used to determine whether a viable gas or oil resource is present. The outcomes of this could provide insight into potential alternative supply options to inform the future energy planning and policy for South Africa. Considering this, and other new information on supply options, as well as the rapid technological advancements in the energy sector (and specifically in the low carbon alternatives), it is crucial that the energy planning for South Africa is continually reassessed and revised to ensure that the most suitable and sustainable strategy is defined. The 2021 NDC's are aligned with the IRP 2019. The GHG emissions and associated climate change impacts associated with the seismic survey itself would be negligible. There are no significant GHG emissions directly related to the proposed activity nor significant climate change vulnerability risks. As such, the life-cycle of the project would be limited to the Reconnaissance activities only (i.e. identification only – and does not necessarily imply actual exploration or further production of oil and gas resources) and	

[16] For example, the offshore wind industry does not use airguns, and instead relies on High Resolution Geophysical (HRG) surveys to map the ocean bottom and its shallow geological features. That technology, such as echosounders, sidescan sonar, and sparkers, uses considerably less power as compared to seismic airguns and also tends to operate at higher frequencies. Not only do higher frequency sounds dissipate more quickly in the ocean but they also tend to fall outside of the general hearing range of baleen whales, such as humpbacks and right whales. The use of seismic surveying to develop offshore wind is the equivalent of using a hammer when a feather could do the job. The area that is being surveyed is also 120 – 230 km offshore and includes deep to ultradeep depths between 1,500 – 4,000m. It would not be feasible to install a fixed nor floating turbines at those depths, as they are more suitable for depths of less than 50m and 50 to 1,000m, respectively. Lastly, a World Bank analysis does not find the area TGS is surveying to be ideal for offshore wind generation. ESMAP. 2019. Going Global: Expanding Offshore Wind to Emerging Markets at p. 20-21. Washington, DC: World Bank ("fixed foundation is considered technically viable in areas with water depth less than 50 m and average wind speeds over 7 m/s. Floating wind is considered technically viable with water depths from 50 m up to 1,000 m.").

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
20. The FBAR states that from a climate change perspective, it is '*not currently possible to accurately assess the risks associated with oil and gas activities, given that the specific details of these potential future activities are not known and therefore climate change impacts would need to be assessed in detail during any subsequent Scoping and EIA processes for any potential subsequent oil and gas production projects*'.[18] As a result, the FBAR does not conduct any climate change impact assessment, even in broad terms. 21. It is relevant to note that the issue of whether the decision-maker properly considered climate change impacts was referred to in the judgment of the full bench of the Makhanda High Court in the Shell Wild Coast seismic survey case.[19] The court stated in its judgement that the intervening parties' contention that the decision-maker gave no proper consideration to climate change impacts of the decision to grant the exploration right is an important factor to be considered in the process of granting an exploration right. The court referred to expert testimony relied upon to support this contention, which showed that '*most of the discovered reserves of oil and gas cannot be burnt if we are to stay on the pathway to keep global average temperature increases below 1.5 degrees Celsius. Authorising new oil and gas exploration, with its goal of finding exploitable oil and/or gas reserves and consequently leading to production, is not consistent with South Africa complying with its international climate change commitments*'.[20] 22. The court noted that according to the respondents in that case, climate change considerations are irrelevant when considering an	this has been specified and defined in the Need and Desirability, and the associated impacts identified and assessed. The statement made by the Appellent that the Need and Desirability is misleading and unlawful in that it considers "*positive impacts should oil and gas be eventually produced, such as the claim that it will provide energy security to South Africa*" is in itself misleading and inaccurate. In fact, the Need and Desirability clearly states that "*The proposed project aims to identify oil and gas resources and will not, at this stage, involve the use of the natural resources identified as part of the proposed survey project*" and furthermore makes no claims of any significant positive impacts and states on numerous occasions that "*The proposed activities are anticipated to have low negative ecological impacts. Refer to the impact assessment in Section 9 in this report.*" Also noted is that TGS is a seismic data acquisition company and is in the business of data acquisition, and are not an Oil & Gas Exploration or Production company. Data from TGS' seismic libraries are not only used for petroleum and natural gas exploration and development, data may also be used for development of offshore wind, geothermal energy, low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
application for an exploration right, and these considerations are premature because they fall to be considered at a much later stage. 23. The court pointed out that on the authority of the *Save the Vaal* case,[21] the '*processes are discrete stages in a single process that culminates in the production and combustion of oil and gas, and the emission of greenhouse gases that will exacerbate the climate crisis and impact communities' livelihoods and access to food*'.[22] The court went on to state that the respondent's thesis does not find support in *Earthlife Africa Johannesburg v Minister of Environmental Affairs and Others* either, and referred approvingly to the following passage in Murphy J's judgement: The absence of express provision in the statute requiring a climate change impact assessment does not entail that there is no legal duty to consider climate change as a relevant consideration and does not answer the interpretative question of whether such a duty exists in administrative law. Allowing for the respondents' argument that no empowering vision in NEMA or the regulations explicitly prescribes a mandatory procedure or condition to conduct a formal climate change assessment, the climate change impacts are undoubtedly a relevant consideration as contemplated by section 240 of NEMA for the reasons already discussed. A formal expert report on climate change impacts will be the best evidentiary means of establishing that this relevant factor in its multifaceted dimensions was indeed considered, while the absence of one will be symptomatic of the fact that it was not.[23] 24. The court in the Shell Wild Coast seismic survey case went on to state the following:	The Earthlife Africa case referred to relates to the EA issued to construct and operate a new coal fired power station which bears no resemblance to seismic survey data acquisition. It is agreed that pending the outcome of an appraisal on the viability of extracting any oil or gas resource, which this seismic survey is likely to inform, due caution will need to be taken to avoid overcommitments and stranded assets. In terms of the "Need for Seismic Data", the main aim of the Needs and Desirability Section of the BA Report is to determine the need for the activity, and it is argued for that the survey is desirable given the current energy planning of the country, amongst other factors It is agreed, considering the rapid technological advancements in the energy sector, that there is a need to continually reassess and revise where relevant the energy planning and policy for South Africa. Pending the outcome of an appraisal on the viability of extracting any oil or gas resource, which this seismic survey is likely to inform, due caution will need to be taken to avoid overcommitments and stranded assets associated with the timing of South Africa's prevailing climate change commitments. The potential for methane leaks during resource extraction, processing, and utilisation will need to be assessed as and when such is proposed. It should further be noted that the acquisition of seismic survey data is considered important with respect to understanding the potential for future oil and gas production as part of the energy mix of the country

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
It seems clear from the aforegoing, even taking into account the contentions raised by the respondents, that, had the decision-maker had the benefit of considering a comprehensive assessment of the need and desirability of exploring for new oil and gas reserves for climate change and the right to food perspective, the decision-maker may well have concluded that the exploration is neither needed nor desirable.[24] (emphasis added) 25. The Green Connection and Natural Justice submit that the FBAR is deficient, and the Needs and Desirability analysis incomplete, without at the very least a broad assessment of the climate change impacts should commercially exploitable oil and gas resources be identified through the proposed seismic survey (and should these resources be produced and utilised). It would be pointless to authorise this (and other) 3D seismic surveys should such an assessment conclude that the development of new oil and gas fields is incompatible with South Africa's climate change commitments. *The 'climate crisis'* 26. The need and desirability (from a climate change perspective) of conducting a 3D seismic survey (which – as mentioned above – the FBAR aims to identify oil and gas resources to be used in energy production and/or processing or manufacturing of materials) is particularly important given that climate change has been acknowledged as a 'crisis' with human-induced climate change impacts being experienced in every region. It is also recognised that the climate change 'crisis' requires immediate, rapid and large-scale reductions in greenhouse gas (GHG) emissions to limit global warming to 1.5°C (including accelerated action in this decade to reduce global carbon dioxide emissions by 45 per cent by 2030 relative to the 2010 level and to net-zero around mid-century). In	going forward. The seismic data will provide information with which future decisions can be made. The South African legislation requires the payment of royalties and taxes to the South African government associated with the extraction of resources. There are further obligations on holders of mineral and petroleum rights to contribute to local economic development. The Draft Upstream Petroleum Resources Development Bill also provides for the state to receive a 20% carried interest in exploration and production rights. According to the specialist investigations undertaken, there is unlikely to be a significant impact on the marine environment and therefore there is not anticipated to be a consequent impact on the right to food. It should further be noted that, in the recent Presidential Climate Commission (PCC) recommendations on the electricity system which also specifically considered many local and international studies (including some of those cited by the appellant), the PCC expects a policy adjusted IRP to promote approximately 50 to 60 GW of variable renewable energy by 2030, supported by co-located storage, and between 3 and 5 GW of peaking support (for example gas, running at low utilisations). Therefore, although the PCC doesn't advocate for large scale new coal or gas the PCC does recommend the inclusion of up to 5GW of peaking support (typically to be provided in part by gas). In summary, the re-evaluation of South Africa's energy planning and policy falls beyond the scope of this assessment. The current policy provides for a portion of the electricity mix to be provided by gas, and that such has been accounted for and included in the countries climate change commitments (NDC's). The source of the gas to meet this need would either be imported of produced locally. The feasibility of the later can only be defined once the extent if the resources have been defined.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
support of these submissions, some of the recent developments relating to the climate crisis are discussed briefly below. 27. In August 2021, the Intergovernmental Panel on Climate Change (IPCC) [an international body for assessing the science related to climate change] released its 6th Assessment Report (AR6).[25] In its summary for policymakers, the IPCC indicates (among other things) that: 27.1. It is unequivocal that human influence has warmed the atmosphere, ocean and land, and that widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred;[26] 27.2. The scale of recent changes across the climate system as a whole – and the present state of many aspects of the climate system – are unprecedented over many centuries to many thousands of years;[27] 27.3. Human-induced climate change is already affecting many weather and climate extremes in every region across the globe. Evidence of observed changes in extremes such as heatwaves, heavy precipitation, droughts, and tropical cyclones, and, in particular, their attribution to human influence, has strengthened since AR5;[28] 27.4. Global surface temperature will continue to increase until at least mid-century under all emissions scenarios considered, and that global warming of 1.5°C and 2°C will be exceeded during	Thereafter a decision can be taken as to whether the resource should be extracted or produced. The EA was issued for seismic survey only and does not result in any stranded assets, but aims to provide information on potential resources. Assessment and analysis of the data acquired by this survey will help inform the Government's decisions on the viability and impact of producing any located assets compared to importing equivalent energy resources.

the 21st century unless deep reductions in CO_2 and other GHG emissions occur in the coming decades;[29] 27.5. Many changes in the climate system become larger in direct relation to increasing global warming. They include increases in the frequency and intensity of hot extremes, marine heatwaves, heavy precipitation, and, in some regions, agricultural and ecological droughts; an increase in the proportion of intense tropical cyclones; and reductions in Arctic sea ice, snow cover and permafrost;[30] 27.6. Continued global warming is projected to further intensify the global water cycle, including its variability, global monsoon precipitation and the severity of wet and dry events;[31] 27.7. Many changes due to past and future GHG emissions are irreversible for centuries to millennia, especially changes in the ocean, ice sheets and global sea level;[32] 27.8. From a physical science perspective, limiting human-induced global warming to a specific level requires limiting cumulative CO_2 emissions, reaching at least net zero CO_2 emissions, along with strong reductions in other GHG emissions. Strong, rapid and sustained reductions in CH_4 emissions would also limit the warming effect resulting from declining aerosol pollution and would improve air quality.[33] 28. On 9 August 2021, the IPCC issued a press release relating to its AR6 report. It states that the report provides new estimates of the

chances of crossing the global warming level of 1.5°C in the next decades, and finds that unless there are immediate, rapid and large-scale reductions in GHG emissions, limiting warming to close to 1.5°C or even 2°C will be beyond reach.[34] 29. Also on 9 August 2021, UN Secretary-General António Guterres described the AR6 report as nothing less than "*a code red for humanity. The alarm bells are deafening, and the evidence is irrefutable*". (emphasis added) 30. Guterres is reported as noting that the internationally agreed threshold of 1.5 degrees above pre-industrial levels of global heating was perilously close, and that we are at imminent risk of hitting this threshold in the near term. Guterres is indicated as advising that the only way to prevent exceeding this threshold, is by urgently stepping up our efforts, and pursuing the most ambitious path. Guterres is reported as stating that solutions are clear: "*Inclusive and green economies, prosperity, cleaner air and better health are possible for all, if we respond to this crisis with solidarity and courage*". Ahead of the COP26 climate conference in Glasgow in November 2021, Guterres stated that all nations needed to join the net zero emissions coalition, and reinforce their promises on slowing down and reversing global heating "*with credible, concrete, and enhanced Nationally Determined Contributions (NDCs)*" that lay out detailed steps. 31. In April 2022, Guterres tweeted that '*[c]limate activists are sometimes depicted as dangerous radicals. But the truly dangerous radicals are the countries that are increasing the production of fossil fuels. Investing in new fossil fuels infrastructure is moral and economic madness*'.[35] Addressing graduate students in May 2022, Guterres expressed the view that investing in fossil fuels is now "a

dead end - economically and environmentally. No amount of greenwashing or spin can change that. So, we must put them on notice: Accountability is coming for those who liquidate our future."[36] 32. The 26th Conference of the Parties of the UNFCCC (COP26) was held in Glasgow in the last quarter of 2021. Recognition of the climate 'crisis', as well as the urgent need to increase effort and to accelerate action to address climate change (including by developing nations), are reflected in the outcome of COP26 and recorded in the Glasgow Climate Pact. The Glasgow Climate Pact (among other things): 32.1. Expresses alarm and utmost concern that human activities have caused around 1.1°C of global warming to date and that impacts are already being felt in every region; 32.2. Reaffirms the long-term global goal to hold the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change; 32.3. Recognizes that the impacts of climate change will be much lower at the temperature increase of 1.5°C compared with 2°C and resolves to pursue efforts to limit the temperature increase to 1.5°C, 32.4. Recognizes that limiting global warming to 1.5°C requires rapid, deep and sustained reductions in global GHG emissions, including reducing global carbon dioxide emissions by 45 per cent by 2030 relative to the 2010 level and to net zero around mid-century as well as deep reductions in other GHGs;

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
32.5. Also recognizes that this requires accelerated action in this critical decade, on the basis of the best available scientific knowledge and equity, reflecting common but differentiated responsibilities and respective capabilities and in the context of sustainable development and efforts to eradicate poverty; 32.6. Invites Parties to consider further actions to reduce by 2030 non-carbon dioxide GHG emissions, including methane which has been identified as a driver of climate change and the main polluting emission from natural gas; 32.7. Calls upon Parties to accelerate the development, deployment and dissemination of technologies, and the adoption of policies, to transition towards low-emission energy systems, including by rapidly scaling up the deployment of clean power generation and energy efficiency measures, including accelerating efforts towards the phasedown of unabated coal power and phase-out of inefficient fossil fuel subsidies, while providing targeted support to the poorest and most vulnerable in line with national circumstances and recognizing the need for support towards a just transition; 32.8. Emphasizes the importance of protecting, conserving and restoring nature and ecosystems, including forests and other terrestrial and marine ecosystems, to achieve the long-term global goal of the Convention by acting as sinks and reservoirs of GHGs and protecting biodiversity, while ensuring social and environmental safeguards. 33. The climate 'crisis' is also recognised by the International Energy Agency (IEA), of which South Africa is an IEA associated country. During or about July 2021, the IEA published its *Net Zero by 2050 – A Roadmap for the Global Energy Sector* report. In the foreword to this report, the Executive Director of the IEA states (among other things) as follows:		

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
We are approaching a decisive moment for international efforts to tackle the climate crisis – a great challenge of our times. The number of countries that have pledged to reach net-zero emissions by mid-century or soon after continues to grow, but so do global greenhouse gas emissions. This gap between rhetoric and action needs to close if we are to have a fighting chance of reaching net zero by 2050 and limiting the rise in global temperatures to 1.5 °C. Doing so requires nothing short of a total transformation of the energy systems that underpin our economies... Despite the current gap between rhetoric and reality on emissions, our Roadmap shows that there are still pathways to reach net zero by 2050. The one on which we focus is – in our analysis – the most technically feasible, cost-effective and socially acceptable. Even so, that pathway remains narrow and extremely challenging, requiring all stakeholders – governments, businesses, investors and citizens – to take action this year and every year after so that the goal does not slip out of reach. This report sets out clear milestones – more than 400 in total, spanning all sectors and technologies – for what needs to happen, and when, to transform the global economy from one dominated by fossil fuels into one powered predominantly by renewable energy like solar and wind. Our pathway requires vast amounts of investment, innovation, skilful policy design and implementation, technology deployment, infrastructure building, international co-operation and efforts across many other areas. Since the IEA's founding in 1974, one of its core missions has been to promote secure and affordable energy supplies to foster economic growth. This has remained a key concern of our Roadmap, drawing on special analysis carried out with the International Monetary Fund and the International Institute for Applied Systems Analysis. It shows that the enormous challenge of transforming our energy systems is also a huge opportunity for our economies, with the potential to create millions of new jobs and boost economic growth.		

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Another guiding principle of the Roadmap is that clean energy transitions must be fair and inclusive, leaving nobody behind. We have to ensure that developing economies receive the financing and technological know-how they need to continue building their energy systems to meet the needs of their expanding populations and economies in a sustainable way. It is a moral imperative to bring electricity to the hundreds of millions of people who currently re deprived of access to it, the majority in of them in Africa... 34. On fossil fuels used in energy production, the report states that: ***There is no need for investment in new fossil fuel supply in our net zero pathway.*** Beyond projects already committed as of 2021, there are no new oil and gas fields approved for development in our pathway, and no new coal mines or mine extensions are required. 35. When natural gas is burned for energy, it releases carbon dioxide into the atmosphere. More importantly, the extraction, processing, transport and use of natural gas cause significant amounts of methane to be released into the atmosphere too. *According to the United Nations, **methane is a 84-86 times more potent greenhouse gas than carbon dioxide over a 20-year period, and 28-34 times more potent over 100-year period.***[37] More research is also showing that methane often leaks during the production, transport and use of natural gas. Therefore, its contribution to climate change is significantly unaccounted for.[38] Drones, laser absorption spectroscopy, and satellites, among other new methane monitoring technologies, have improved the identification and quantification of emissions across the gas lifecycle, leading researchers to conclude

[38] South Africa is likely among those that are underreporting because the Technical Guidelines for GHG reporting uses outdated emission factors from the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
that national governments have almost universally underestimated these emissions.[39] 36. If 3,000 megawatts of new gas-to-power plants were built to meet South Africa's 2019 Integrated Resource Plan for Electricity, and the plants were fuelled by imported LNG, the annual emissions from this fuel use would be more than 2.5 million tonnes of CO_2e (carbon dioxide equivalent) if the plants ran at 75% capacity. This is the equivalent of driving over half a million gasoline-powered vehicles for a year.[40] For gas or any other fossil fuel, a life-cycle analysis is therefore necessary to quantify the total amounts of GHG emissions (predominantly carbon dioxide and methane) that result from every step in the energy production process: from extracting the fossil fuel at the well or mine to burning it at a power plant or other facility. This is therefore important because all these processes are linked and should not be viewed in isolation. ***South Africa's international climate change commitments*** 37. South Africa is a Party to the United Nations Framework Convention on Climate Change (UNFCCC), which enjoins State Parties to take precautionary measures to anticipate, prevent or minimize the causes of climate change (Article 3.3). 38 South Africa, as a Party to the UNFCCC that ratified the Kyoto Protocol and adopted the Paris Agreement, has committed to *'working with others to ensure temperature increases are kept well below 2°C above pre-industrial levels, which could include a further revision of the temperature goal to below 1.5°C in light of emerging*

[42] Paris Agreement, Article 4.19

[43] Available online at https://www.dffe.gov.za/sites/default/files/reports/draftnationallydeterminedcontributions_2021updated.pdf#:~:text=South%20Africa%E2%80%99s%20intended%20nationally%20determined%20contribution%20%28INDC%29%28RSA%2C%20n.d.%29,Agreement.%20The%20INDC%20and%20first%20NDC%20are%20identical. This revised NDC is indicated as an enhancement and update of South Africa's NDC under the Paris Agreement, 'meeting its obligation under Article 4.9 to communicate NDC's every 5 years, and responding to requests in paragraphs 23 to 25 of decision 1/CP.21'. South Africa's second (next) NDC is intended to be communicated in 2025.

41. South Africa's energy sector is estimated at contributing about 84% percent to the country's overall GHG emissions (including Carbon Dioxide and Methane).[44] 42. In February 2020, South Africa submitted to the UNFCCC its first long-term low GHG emission development strategy titled *South Africa's Low Emission Development Strategy 2050*. It is indicated in the executive summary of this strategy that South Africa, as one of the top 20 global GHG emitters and with a high dependency on fossil fuels, will need to make substantial emission cuts to contribute its fair share to global GHG emission reductions.[45] 43. The FBAR does not provide any indication (or estimation) of how future GHG emissions (resulting from future exploitation of oil and gas that may be discovered through the exploration drilling project) would impact on South Africa's ability to achieve its GHG emissions targets (as set out in South Africa's NDC) or its updated GHG emissions targets (as set out in South Africa's revised NDC). This is particularly relevant given that the emissions targets for the 2026-2030 period are lower than the targets for the 2021-2025 period, while offshore oil and gas developments could take at least a decade to reach the production stage. This could result in offshore oil and gas investments (as well as associated gas infrastructure developments) in the future becoming unneeded 'stranded assets' and a burden on future generations. There is also a risk that in the future tariffs will be levied on various goods exported by fossil-fuel dependent countries – the European Union is reported to be

gradually phasing in its Border Adjustment Mechanism as part of the EU's Green Deal.[46] ***Need for seismic data*** 44 Under the sub-heading 'Need for seismic data', the FBAR states that a discussion of the needs and desirability of the project '*would not be complete without understanding the need for acquisition of the seismic data and possible oil and gas exploration and production that could potentially take place in the future as a result of the survey*'.[47] 45. Ironically, the FBAR then quickly goes on to state that *'It cannot be said with absolute certainty that exploration drilling, let alone production activities, will be undertaken in the future. As such, it is not currently possible to accurately assess the risks associated with these activities, given that the specific details of these potential future activities are not known. While it is acknowledged that the risks mentioned would need assessment, such assessment falls outside of the scope of the current application and would need to be assessed in detail during subsequent Scoping and EIA processes, should exploration drilling or production be proposed. The environmental consequences applicable to the planned survey activities have been identified and assessed in this BA Report'*.[48] The views of the Makhanda High Court in this regard (in the context of future production, climate change and the right to food) have been traversed earlier in the Green Connection and Natural Justice's comments (see paragraphs 27 to 30 above) and are not repeated here. The Green Connection and Natural Justice stands by their view that at the very least a broad assessment of the impacts and risks

associated with future invasive exploration activities, production activities and use of any discovered oil reserves should be included in the BAR. 46. The FBAR report then proceeds with a glowing (and one-sided) endorsement of the use of natural gas: The fastest growing sector for the use of natural gas is for the generation of electric power. Natural gas power plants usually generate electricity in gas turbines, directly using the hot exhaust gases from the combustion of the gas... Of the three fossil fuels used for electric power generation (coal, oil and natural gas), natural gas emits the least carbon dioxide per unit of energy produced. Natural gas emits 30% and 45% less carbon dioxide than burning oil and coal, respectively. Burning natural gas also releases lower amounts of nitrogen oxides, sulphur dioxide, particulates and mercury when compared to coal and oil. The increased use of natural gas can, in the short term, serve as a transition fuel on the path to the carbon-neutral goal of the Paris Agreement. In addition to gas as a key transitional fuel reducing reliance on coal, the benefits of oil and gas could include significant amount of job creation, especially if local beneficiation takes place. An increase in domestic natural gas reserves would enable South Africa to take steps to secure the countries' energy supply (through diversification), assist in reducing the emissions of greenhouse gases (by reducing the country's reliance on coal for electricity generation) and reduce the need for the importation of gas. As such, exploration for additional domestic hydrocarbon reserves is considered important and supported by national policy, and any discoveries would be well received by the local market and are consistent with the objectives stated in the 2019 IRP. Natural gas emits 30% and 45% less carbon dioxide than burning oil and coal, respectively, and 65% less carbon dioxide than coal when the increased efficiency of Combined Cycle Gas Turbines versus coal fired power stations is considered. Eskom produces over 200MtCO2/yr, over 40% of South Africa's total. South Africa also has SASOL's Secunda coal to liquids		

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
plant, the biggest single source of CO2 in the world at 57MtCO2/yr (~12.5% of South Africa's total) to produce 160k barrels of products per day. Supplying these products from conventional oil production and refining would generate approximately 10% of those emissions, 5 to 6MtCO2/yr. According to the 2019 IRP the availability of gas in the short to medium term is a risk as South Africa does not currently have gas resources. There is also a supply and foreign exchange risk associated with likely increase in gas volumes depending on the energy mix adopted post 2030 when a large number of coal fired power stations are decommissioned. South Africa's economic growth is dependent on the availability of energy, ensuring a sustainable and reliable supply of electricity with sufficient capacity is a key aspect to growing the economy of South Africa in the future. The electricity shortages experienced in South Africa over the past decade are a contributing factor to the significant slowdown in economic growth rate. To enable economic growth within the target rate of between 6% and 8% to be achieved, it will be necessary for Government to continue increasing electricity generating capacity in the country. The use of natural gas for electricity generation is identified in national policy, together with renewable energy technologies, as an alternative in diversifying the domestic energy supply away from its current reliance on coal. Gas is identified in the draft Integrated Resources Plan as significant contributor to South Africa's energy mix in the period up to 2030. Availability of gas also provides an opportunity to convert to Combined Cycle Gas Turbine and run open-cycle gas turbine plants at Ankerlig (Saldanha Bay), Gourikwa (Mossel Bay), Avon (Outside Durban) and Dedisa (Coega IDZ) on gas (IRP 2019).[49] 47. Perhaps concerned that it is making the case that seismic surveys are indeed the 'thin edge of the wedge' that will lead to increased fossil fuel extraction, production and use (with associated climate change		

[49] Ibid

Initials

1955

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
impacts), the BAR steps back from its natural gas endorsement to repeat the point that *'[f]rom a climate change perspective, it is not currently possible to accurately assess the risks associated with oil and gas activities, given that the specific details of these potential future activities are not known and therefore climate change impacts would need to be assessed in detail during any subsequent Scoping and EIA processes for any potential subsequent oil and gas production projects'.*[50] 48. The FBAR then proceeds to argue that: The feasibility of using natural gas for domestic power generation is considered to be dependent on the extent of available domestic reserves of natural gas, as well as the financial cost of importing natural gas should those reserves be insufficient. The acquisition of seismic survey data is therefore considered important with respect to understanding the potential for future oil and gas production as part of the energy mix of the country going forward and the need and desirability of the project is therefore supported from an energy security perspective.[51] 49. We note here that despite reliance on the IRP to motivate for the project, the FBAR fails to assess whether the amount of gas called for in the IRP would in any event require the exploitation of the resources sought by TGS. 50. Two recent independent studies (among others) challenge the view that fossil gas is necessary for electricity generation and as a transition fuel. 51. The International Institute for Sustainable Development's (IISD) *Gas Pressure: Exploring the case for gas-fired power in South Africa* (March 2022) report points out that while there used to be a rational view that fossil gas would be necessary either during a transition to		

[50] Ibid.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
low-carbon energy or as part of the long-term energy mix for electricity production: ....revolutions first in renewable energy costs and then in battery storage costs have upended this view. Analysis of the South African electricity system shows that gas supply is not technically necessary until at least 2035, if ever. In the last few years, either the risks associated with gas have increased, or the understanding of existing risks has increased. Consequently, South Africa may see significant negative outcomes from developing a large gas-to-power system now... the trend toward decarbonization, coupled with cost reductions for renewable energy and storage, creates risks for gas investment. Investment in gas can reasonably be expected to lead to higher costs for consumers, just transition challenges for workers, and losses for investors.[52] 52. The ISSD report highlights some of the risks associated with gas-to-power investment in South Africa. These risks include significant contributions to climate change (as a consequence of CO_2 and methane emissions when gas is burned), increasing international pressure to move away from gas due to climate impacts, financial risks linked with gas-to-power, the risk of reduced security of affordable gas supply, the risk of stranded assets, and the risk of creating an additional just transition burden (future gas workers and communities face a repeat of the transition hardships currently faced by the coal sector).[53] 53. Meridian Economics' *'Hot Air about Gas – An Economic Analysis of the Scope and Role for Gas-Fired Power Generation in South Africa'* (June 2022) report points out that while South Africa's large-scale use of gas appears to be central to current energy policy direction in South Africa, *'this rests on a 2012 vision which pre-dates dramatic*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
reductions in renewable energy costs and carbon emissions space'.[54] The report goes on to state that independent analysis of the power sector across multiple recent studies shows that South Africa's power needs can be met both now and in the future with very little use of gas, and that there is *'no evidence to support the large-scale gas envisaged in the GMP; this is uneconomical even before carbon emissions are considered'.*[55] Meridian point out that *'the assumption that gas-fired power generation would replace coal ignores the fact that other technology combinations are now better at replacing coal-fired power than gas, and it is against these technologies that gas-fired generation should actually be compared'.*[56] Meridian demonstrate that existing modelling provides no economic rationale for "big gas" in the power sector, and that *'the impact of using large volumes of gas to generate power will be borne by electricity consumers and will essentially be a subsidy provided by power consumers to otherwise unviable gas use in other sectors'.*[57] 54. The Vital Ambition Report[58] by Meridian Economics in collaboration with the Council for Scientific and Industrial Research ("CSIR") Energy Centre ("Vital Ambition Report") states that gas to power is only justified in the South African energy mix in so far as it is required for low-utilisation flexible capacity (peaker plants) for balancing the system during peak power demand. The report confirms that no investments in gas infrastructure for energy production and generation is needed now or in the near future.[59] Furthermore the

2019 IRP will likely need to be updated in the foreseeable future to align with South Africa's 2021 Nationally Determined Contribution under the Paris Agreement and to keep pace with quickly evolving science and significant reductions in price for solar and wind energy. However, even the 2019 IRP, which is rooted in an outdated and scientifically and economically unsound understanding of the necessity for any gas in the energy mix[60], only projects the collective contribution of gas and diesel to the 2030 energy mix to be 1.3% combined.[61]		
55. According to a recent report prepared by Robert W. Howarth titled "Methane emissions and climate warming risk from hydraulic fracturing and shale gas development: implications for policy"[62] the climate impacts of gas are greater than those of coal per unit of energy produced when evaluated over a 20-year timeframe, the period most relevant for climate change if humans are to avoid catastrophic run-away warming. Though gas emits less carbon dioxide per unit energy than coal, its upstream GHG emissions are more problematic for the climate, as it leaks and vents potent methane throughout its lifecycle; researchers have been able to better detect emissions across the lifecycle of gas ever more accurately thanks to new methodologies and technologies (particularly "top-down" measurements using satellite and aerial assessments).		
56. The use of fossil fuels must be phased out quickly due to the urgent need to address global warming. A recent study published in *Nature*,

the world's leading multidisciplinary science journal, discovered that "by 2050, we find that nearly 60% of oil and fossil methane gas, and 90% of coal, must remain unextracted to stay within a 1.5 °C carbon budget." According to the study, "most regions must reach peak production now or within the next decade, making many operational and planned fossil fuel projects unviable."[63] It is common practice that proposed exploration activities such as reconnaissance, only commence months and sometimes years after the need and desirability assessment is undertaken, with extraction and production only commencing years later.[64] According to one study, the world's largest oil and gas fields took an average of 5.5 years from discovery to first production and 17 years to reach peak output.[65] Chevron Corporation's (CVX) Gorgon natural gas development project off the coast of Australia took 30 years to complete, and another six years to begin producing liquefied natural gas.[66] Therefore exploration projects whose objectives are to locate gas deposits for energy companies to exploit through the construction and production of fossil fuels, run the risk of creating risks for such infrastructure to become stranded assets which invariably impacts on the development potential of South Africa in achieving its climate goals. With no economic justification for large-scale gas use in power, such a strategy would result in assets that are stranded before their first kWh of power is generated. Given this, the proposed reconnaissance

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
project in no way provides a remedy nor will address in the immediate future South Africa's current energy insecurity issues. 57. Importantly, seismic surveys to explore for oil and gas will not have any immediate impact on South Africa's energy security, as any oil and gas extracted would not belong to South Africa, but would invariably belong to the companies that extract for profit.[47] Energy companies compete for access to mineral rights granted by governments by either entering a concession agreement, meaning any discovered oil and gas are the property of the producers, or form part of a production-sharing agreement which favours the interest of the producers and ultimately diminishing the general interests of the broader South African Republic. 58. The oil and gas that will be eventually extracted by oil and gas companies is ultimately exploited for profit. It is not used to generate a benefit that results in broad based security for energy production nor does it lead to the production of energy for South Africa and its citizens. If oil and gas found following a successful reconnaissance, and that are ultimately exploited, are not used to produce energy for South Africa, this invariably undermines the sole stated goal underpinning the need and desirability of this proposed reconnaissance project—its supposed contribution to energy security for South Africa—and provides no tangible benefit for South Africans. 59. While the increased use of gas as a 'transitional fuel' is promoted by government and vested interest groups, the Green Connection and Natural Justice submit that the increased use of fossil gas (especially in electricity generation) will lead to increased emissions of climate warming GHGs, and methane (CH_4) in particular. While natural gas combustion is less carbon-intensive than that of coal, fugitive emissions arising from the production, transport, storage and use of natural gas have a much greater climate impact than CO_2. In

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
particular, over a 20-year period (which is particularly relevant since the next 20 years are a critical window for addressing the climate crisis) methane emissions, which make up approximately 70-90% of natural gas emissions, are projected to be 82.5 times as impactful as those of CO_2.[69] The desirability of using gas as a 'transitional' fuel is also questionable having regard to volatile international gas prices, as well as the potential risk of Carbon Border Taxes being introduced in the future.[70] This risk will impose restrictions on the export of products with a high carbon footprint, putting South Africa's economy at greater risk of developing gas to power rather than clean renewable alternatives. This invariably diminishes the need and desirability for promoting new gas development projects, as the negative climate impacts and financial risks undermine the potential for gas to represent a viable solution for South Africa's ambitions to address development whilst respecting universal and regional climate change obligations.		
60. The fundamental outcome of the need and desirability assessment should not be centred on the determination of whether gas technology will ensure security of supply for electricity. Instead, due to the climate crisis, this assessment should be centred on whether South Africa needs, or should rely on, gas to provide security of supply of electricity and whether alternative technologies could meet the same supply objectives with less harm and risk. Renewable energy and/or storage can replace gas to provide reliable and cost-effective generating capacity while greatly reducing the environmental and health risks associated with gas.[72]

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
61. The call for gas as part of the energy mix set forth in the 2019 IRP does not excuse the decision-maker from taking climate change impacts into account, including as part of the need and desirability assessment. The case for need and desirability must address climate impacts and cannot simply rest on the 2019 IRP as evidence of need or desirability as relied upon by the EAP in the BAR. In the judgment of the High Court in *Earthlife Africa*[71], the court expressed that with respect to a decision maker's reliance on the IRP when rendering a decision on an application for environmental authorisation, the following is important to acknowledge: (a) "Policy instruments developed by the Department of Energy cannot alter the requirements of environmental legislation for relevant climate change factors to be considered".[72] (b) Establishing the need and desirability of a proposed project, is a key objective of each stage of scoping and impact assessment and must account for South Africa's 2021 NDC under the Paris Agreement. The EAP must therefore provide a broad and robust analysis of multiple alternative literature on renewable energy resources and make a justifiable and reasonable case for a project's need and desirability having considered the available literature, without relying solely on the 2019 IRP and other policy documents. This invariably assists the decision maker to prioritise the granting of the best decision which will prioritize the integrity of the environment, and the social welfare, health and safety aspects of the socio-economic environment for present and future generations.		
Ground 2: Failure to adequately consider marine impacts. *Underwater sound from seismic surveys*	The importance of sound is clearly acknowledged in the BAR and consequently a dedicated acoustic modelling assessment was prepared as part of the BAR. EIMS appointed experienced and qualified scientists

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
62. The ocean is an acoustic world. This is because water is a dense medium, and sound travels faster and farther underwater. Marine species, from larvae to whales, utilise this efficiency and have evolved to depend on sound for essential biological functions, including feeding, breeding, communicating, navigating, and socializing.[73] 63. Sound is also a fundamental component of marine habitats. Different ocean environments have distinct acoustic signatures that comprise their acoustic habitat. These acoustic habitats are created from a combination of biological sounds (e.g., fish choruses, snapping shrimp, urchin movement, whale calls) and environmental sounds (e.g. waves crashing, rain, earthquakes). The addition of anthropogenic noise to these soundscapes disrupts the abilities of marine species to use naturally occurring acoustic cues and has detrimental effects on individual organisms, populations, and communities.[74] 64. Seismic airgun blast are the loudest human-created noises introduced into the ocean environment and they travel long distances through seawater. Studies have shown that seismic blasts are at least detectable at distances greater than 500-700 km, even up	to assess the likely impacts from seismic noise. The associated noise impacts were a key focus of the BAR and this clearly indicated in Section 9 of the BAR. It should be noted that a qualified and experienced marine ecology specialist was appointed to conduct an assessment of the likely impacts as identified and described in Section 9.3.1of the BAR. The significance rating for each impact is determined through consideration of the nature, extent, duration, magnitude and probability of each impact. Please refer to section 9.1 of the BAR for an explanation of the assessment methodology utilised. The significance of all identified impacts in the marine ecology report, which included the impacts associated with the underwater sound from the proposed seismic survey, were considered to be of low significance once mitigation has been applied. The significance of environmental impacts varies depending amongst others on the specific location, prevailing sensitivities, receptors, timing, and extent of the proposed activities. The EAP and the specialists identified and assessed potential environmental impacts (supported by inputs from the public consultation process) and has	

[73] Supporting Affidavit of Dr. Aaron N. Rice at paras. 8, *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, attached marked Annex B1; Supporting Affidavit of Dr. Douglas P. Nowacek at paras. 9 & 13, *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, attached marked Annex B2.

This appeal incorporates the expert opinions of Dr. Rice and Dr Nowacek who submitted affidavits in the matter of *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021. Both of the affidavits provide expert insight on underwater acoustics, how marine species utilize acoustic cues for biological processes, and how seismic surveys may impact different taxa. The declarations will be used to assist the court to understand general principles and processes and will not be used to support specific impacts that were associated with that case on the east coast of South Africa.

[74] Rice Supporting Affidavit at para. 12.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
to 4,000 km.[75] Other studies have detected seismic surveys at levels sufficient to mask, or obscure, baleen whale calls at distances of thousands of kilometres away from the source.[76] Airgun noise influences and degrades the acoustic habitat of marine species over a far greater area than the metres and kilometres that the EBAR considers and in fact, according to the science, can easily reach coastal areas 120 – 230 km from the survey area. 65. In addition, the noise produced by airgun arrays becomes virtually continuous at greater distances from the source creating chronic noise impacts. This is because the sounds emanating from a seismic airgun array do not behave as individual and finite sound source *in situ* but reflect off the ocean surface and seafloor as they travel, leading to a continuous increase in the sound level through reverberation. The effect has repeatedly been documented.[77] Studies have found seismic surveys causing elevated ambient noise levels by more than 25 dB (approximately a 4-fold increase in noise levels) across distances of 40 km and these sound levels remain elevated during the periods between airgun blasts.[78] Open ocean condition observations have found that the noise produced and were sustained for months at a time.[79] 66. Because of several flaws in its approach, the EAR does not fully identify and assess the risk posed to marine species and ecosystems and does not effectively mitigate the risks from the proposed the proposed surveying.	proposed management and mitigation measures. The impacts are, by virtue of the fact that the impact assessment is a predictive assessment, regarded as 'potential'. All impacts identified in the process can be reduced to a low or medium significance with the implementation of the management and mitigation measures. All impacts associated with a proposed project are considered potential impacts until the impact actually occurs. The studies undertaken internationally over the past ~70 years on the impacts of noise on marine fauna (of which some 400 peer-reviewed publications have been summarised and cited in the marine faunal specialist study) have concluded that the effects of underwater sounds vary substantially and depend on a wide variety of physical and biological factors. When writing articles on the effects of seismic acquisition on marine fauna it is therefore not difficult to bias the literature cited to either demonstrate detrimental and irreversible impacts or only very limited impacts, depending on the personal view of the author(s) and/or the targeted readership. The marine faunal assessment has made efforts to present published results objectively, and nowhere claims that acoustic surveys do not result in impacts. Injury is likely at very short range, with behavioural disturbance occurring over greater distances. The final significance ratings are determined using information from the peer-reviewed literature together with the noise modelling results (which put the threshold distances from the source array to mortality and

Harms to marine life 67. It is well established that marine seismic surveys cause serious and irreparable harms to marine life. The Biodiversity and Ecosystem Services Assessment Report[40] ("Pisces Report") prepared for the Project acknowledges the a wide range of impacts on numerous species: • Physiological injury and/or mortality; • Behavioural avoidance; • Reduced reproductive success/spawning; • Masking of environmental sounds and communication; • Collision of turtles/marine mammals with the survey and support vessels or entanglement in towed acoustic apparatus; and • Indirect impacts on piscivorous predators due to seismic effects on prey species. 68. According to the Pisces Report, the following species are present in the Project area and face the highest risk of harm from the proposed survey: • humpback whales, which migrate through the area between June and November (inclusive); • sperm whales, beaked whales and other odontocetes that frequent offshore waters; • large migratory pelagic fish and shark species that show seasonal association with Child's Bank and Tripp Seamount;	potential mortal injury into perspective), adopting the precautionary principle as is required when undertaking such impact assessments, and taking into account the sensitivity of receptors present in southern African waters. Given all of the evidence, the conclusion reached for the various assessments is that impacts are either of low or very low significance. The Noise impact on plankton is assessed in Section 9.3.1.1.7 of the BA report. The reconnaissance permit area is located far offshore (120 km at its closest point) and therefore beyond the influence of coastal upwelling, which will influence both plankton abundance and the abundance of fish species that depend on plankton as a food source. From Figures 17, 18 and 19 in the marine ecology specialist assessment it is evident that the project area lies well beyond major fish spawning and recruitment area (and therefore zooplankton and ichthyoplankton abundance). An EIA is a risk-assessment based study and is a process of evaluating the likely environmental impacts of a proposed project or development. It is not possible to provide conclusive evidence of the fact that impacts will be negligible. However, it can be stated with regards to the uncertainties and gaps in knowledge that these have specifically been taken into consideration during the assessment of the particular impacts. The confidence level of the rating has been stated and the level and type of mitigation proposed has followed the clear mitigation hierarchy presented in the Specialist reports and also the EIA Report. Accordingly, the mitigation measures proposed are deemed to be sufficient to account for the eventuality that unforeseen events or organism responses are encountered during the actual survey operations, and will ensure that there is independent oversight and feedback to ensure compliance with the EMPr.	

[40] PISCES Environmental Svcs (Pty) Ltd (for TGS Geophysical Company), *Biodiversity and Ecosystem Services Assessment Report* ("Pisces Report") (Sept. 2022).

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
• leatherback turtles which frequent offshore waters in low numbers and aggregate around seamounts to feed on jellyfish; and • various pelagic Albatross, Petrel, Storm Petrel and Shearwater species (the Pisces report indicates that pelagic seabirds are likely to be relatively frequently encountered in the offshore waters of the Reconnaissance Permit area).[41] 69. A 2022 review of peer-reviewed literature on the physiological, behavioural and ecological impacts of the 3D seismic survey activities on marine wildlife[42] ("Harris Report", attached marked Annex B3) found that the type of sound emitted during seismic surveys has been directly linked to physical damage to marine animals, including soft tissue trauma damage, emboli/ams, damage to organs used in balance and orientation, concussions, haemorrhaging, decompression sickness and both temporary and permanent threshold shifts to hearing ability. The Harris Report also found that some species display physiological stress responses and behavioural changes to seismic activities, such as moving away rapidly, diving or remaining still. These responses are likely to increase their energy consumption and energy costs, reduce their time to forage, and/or affect their vulnerability to predation, thus having negative impacts on the survival of individuals (especially young or compromised animals) as well as the overall population growth and survival of a species (especially for threatened species that are already at risk of extinction). **Acoustic Modelling**	The extent of the TGS survey area is substantively different from that applied for by Searcher in 2021 and which was the focus of the Harris (2002) review. The TGS Application Area is located further from shore and avoids many of the identified sensitive areas and sensitive times of the year. A team of similarly qualified specialists considered the proposed activity, identified and assessed potential impacts, and where applicable made recommendations to manage and mitigate the impacts. All impacts assessed can be reduced to a medium or low significance with the implementation of management and mitigation measures described in the BA report and accompanying EMPr. Please refer to Section 9.3.1 of the BA Report for the assessment of the potential impact on marine fauna (including impact on humpback whales, southern right whales, leatherback turtles, African penguin, and cape fur seal) in the context of the proposed activity. The Appellant's submission that the Acoustic Modelling, is largely a desktop assessment is correct. However, it cannot be stated that the model failed to provide meaningful information as is claimed by the Appellant. The technical noise report relies on predictive modelling to predict the noise impacts associated with the seismic survey. In order to refine and confirm this information, the underwater noise modelling study recommends that "Baseline noise measurements can provide useful information (prior to operations) when interpreting underwater noise predictions for the introduction of a new noise source. As such, it is recommended that underwater noise measurements be implemented

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
70. The Appellants submit that the underwater noise modelling was largely a desktop study rather than a meaningful examination of the acoustic harms that seismic surveying will have. 71. The acoustic modelling failed to provide meaningful information in several ways: 71.1. The model should have included in situ testing to 'ground truth' the modelling and accurately determine the potential noise impacts associated with various aspects of the proposed 3D seismic survey (sound in the ocean is affected by pressure, salinity, temperature and temperature gradients, and can travel many kilometres from the source). 71.2. The model should have assessed the impacts of noise on all species (different species have different sensitivities to noise) during the environmental impact assessment process (not ex post factor). 71.3. The assessment should include (but not be limited to) potential impacts on the migration of snoek (a species that is important to the livelihoods of small-scale fishers) and juvenile turtles (which are significant from a biodiversity perspective given their endangered status) that are in turn dependent on other species. **Heightened Legislative Requirements are Not Considered for Critical Biodiversity Areas (CBAs), Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs)** 72. The National Environmental Management: Biodiversity Act, 2004 ("NEMBA") provides for ecosystems that warrant special conservation attention. These include ecosystems identified as Critical Biodiversity Areas ("CBAs") or Ecological Support Areas ("ESAs") in a bioregional plan, biodiversity sector plan or provincial spatial biodiversity plan.	that would include the deployment of underwater sound monitoring equipment to establish an actual baseline prior to the commencement of the survey and then operational levels of noise during the survey." The migration of snoek has been described in Section 8.5.3.10 of the BA Report. Additionally, the impact of the proposed activity on juvenile turtles is described detail in Section 4.3.3 (Impacts of Seismic Noise on Turtles) of the Marine Ecological Assessment. It is also already recommended in Section 9.3.4.2 of the BA Report as well as the EMPr that TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. The NEM:BA, NEM:PAA and NEM:ICMA are all identified as key pieces of legislation applicable to the proposed project in Section 4 of the BAR. Furthermore, the BAR goes on to discuss CBAs and ESAs in Section 6.2 – CBA 1 indicates irreplaceable or near-irreplaceable sites that are required to meet biodiversity targets with limited, if any, option to meet targets elsewhere, whereas CBA 2 are "best design sites" and there are often alternative areas where feature targets can be met; however, these will be of higher cost to other sectors and / or will be larger areas. Activities within these management zones are classified into those that are "compatible", those that are "not compatible", and those that have "restricted compatibility". Non-invasive (e.g. seismic surveys) and invasive (e.g. exploration wells) exploration activities are classified as having "restricted compatibility". Activities with restricted compatibility require a detailed assessment to determine whether the recommendation is that they should be permitted (general), permitted subject to additional regulations (consent), or prohibited, depending on a variety of factors. Petroleum production is, however, classified as "not	

Initials

1968

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
73. The Appellants contend that the Minister ignored the critical importance of NEM:BA, NEM:PAA and relevant provisions of NEM:ICMA in terms of protecting and conserving the identified CBAs within the survey area, as well as the EBSAs and MPAs. At the very least, the value of these areas and the extent of potential negative impacts of exploratory activities on these areas should have been considered. The BAR failed to provide any assessments for the CBAs contained within the Application Area or the EBSAs and MPAs that are adjacent to the area. <u>CBAs</u> 74 The FBAR failed to meet even minimal standards of providing a "detailed assessment" and relevant mitigation in order to protect irreplaceable and near-irreplaceable CBAs from the intense and chronic blasts of the seismic survey. In fact, the Sound Transmission Loss Modelling report makes no reference to critical biodiversity areas 75. FBAR acknowledges that there are several CBAs within the Application Area itself: *The Application Area overlaps with areas mapped as Critical Biodiversity Area 1 (CBA 1): Natural and Critical Biodiversity Area 2: (CBA 2) Natural. Approximately 32.25 % of the proposed 3D acquisition area is covered by CBA 1 and CBA 2 Natural, 0.22% by CBA 1 and CBA 2 Restore, and 1.75% by ESA (see Figure 91).*[83] 76. CBA 1 are irreplaceable or near-irreplaceable sites that are "required to meet biodiversity targets with limited, if any options to meet targets elsewhere."[84] CBA 2 are best design sites where there may be alternative areas where biodiversity targets can be met at a higher	compatible" in CBAs, but may be compatible, subject to certain conditions, in ESAs. Seismic surveying is not only used for petroleum and natural gas exploration and development. It is also used for development of offshore wind, geothermal energy, and low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes. Therefore the CBA areas are not considered no-go areas for the purposes of seismic survey activities. In addition, the National Coastal and Marine Spatial Biodiversity Plan for the coast and ocean around the South African mainland states that petroleum production may be possible in CBAs using lateral drilling or other techniques that do not result in biodiversity impacts. According to the plan if significant petroleum resources are identified in these areas the selection of the site as a CBA could be re-evaluated, although this would require alternative CBAs to be identified to meet biodiversity targets. The potential impact on MPAs, CBA's and EBSA's is specifically noted in the BAR. A buffer of at least 5 km is recommended around MPAs, as stated in the EMPr. No buffer requirements are proposed by the marine fauna specialist for CBAs or ESBAs as the impact on these areas is expected to be low – negligible. Section 8.6 of the BAR presents the proximity of the planned activities in relation to ecologically or biologically significant areas. There is one Ecologically or Biologically Significant Marine Area (EBSA) overlapping the application area, and this was considered through the selection of the L1 point in order to gauge the effects on the Tripp Seamount to the

1969

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
cost or requiring the allocation of additional area to achieve the targets.[85] 77. The FBAR recognizes that the exploration activities, including seismic surveys, are classified as having restricted compatibility with CBAs, which require a "detailed assessment to determine whether the recommendation is that they should be permitted (general – as is the case for this assessment), permitted subject to additional regulations (consent), or prohibited, depending on a variety of factors."[86] The BAR fails to even identify the unique and irreplaceable features of the CBAs in order to be able to assess whether this activity should be permitted. 78. CBA areas have been identified and set aside, and resources have been invested, in order to protect these biologically critical habitats and the marine species that depend on them. Seismic surveys will run directly over these critical biodiversity areas designated as irreplaceable and near-irreplaceable, causing severe and potentially irreversible impacts. 79. The FBAR has failed to look in detail at the CBAs, understanding why they were identified as critical biodiversity areas, and then propose specific mitigation measures in order to make an informed assessment as to the "restricted capability." <u>EBSAs and MPAs</u> 80 The underwater Sound Transmission Loss Modelling report conducted for the BAR indicates in its introduction that the proposed survey areas are adjacent to a few Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs) including Childs Bank and Shelf Edge, and Cape Canyon and	north. A number of Marine Protected Areas (MPAs) are located adjacent to the proposed survey areas. Section 9.3.1.1.2 of the BAR identifies and assesses the potential impact on Cape Fur Seals. Figure 37 in the marine ecology specialist assessment illustrates the foraging ranges of seals on the West Coast from tracking data. From this it is evident that the survey area lies offshore of these foraging ranges. Additionally, suitable mitigation measures have been proposed to monitor for and protect the seals should they be encountered during the survey in Section 9.3.1.1.2 of the BAR. Section 9.3.1.1.1 and Appendix 3-5 of the BAR identifies and assesses the potential impact on beaked and other whales. This includes a description of the potential impact on: • Physiological injury and mortality; • Behavioural avoidance; • Masking of Sounds and Communication; and • Indirect impacts due to effects on predators or prey. Section 9.3.1.1.1 of the BAR then goes on to state that *"The potential impacts cannot be eliminated due to the nature of the seismic sound source required during surveying. The proposed mitigation measures, which are essentially designed to keep animals out of the immediate area of impact and thereby reduce the risk of deliberate injury to marine mammals would reduce the intensity of most impacts to medium, and the residual impacts will reduce to low consequence and LOW significance, except for the effects on prey which remains of VERY LOW significance."*	

[85] BAR at 162.
[86] BAR at 162

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Associated Islands, Bays and Lagoon.[87] The BAR expands that list adding important areas such as the Benguela Muds MPA, Robben Island MPA, Southeast Atlantic Seamounts MPA and additional MPAs "that fall within the broader project area."[88] The Bar also identifies and describes eight EBSAs, including transboundary relevant to the seismic survey area.[89] 81. Although these protected areas do not fall within the seismic survey area itself, the nature of seismic survey will cause impacts on the habitats and the marine species that these areas are meant to protect. These include endangered and protected species, breeding areas, sensitive and vulnerable habitat, resident whales, and many other features which make the species fragile and sometimes slow to recover, which has warranted their protection. 82. The FBAR makes no effort to identify impacts to these sensitive areas and to mitigate the potentially irreversible harms that the seismic survey will cause. As noted above, the sound from seismic surveys can travel hundreds of kilometres and will penetrate into the MPAs and EBSAs. Further, the seismic surveys will increase the ambient noise beyond the survery area. The chronic blasting every 6-20 seconds for months (70 days) will cause behavioural disturbances and possibly more damage to these sensitive areas, which the BAR did not take into account. **Cape fur seals** 83. In South Africa, since October 2021, thousands of dead and/or dying Cape fur seals, have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely	Section 9.3.1.1.5 of the BAR identifies and assesses the potential impact on pelagic fish. It was concluded that the location of the Application Area well to the west of the 'ring-fenced' area and proposed mitigation measures, which are essentially designed to keep animals out of the immediate area of impact and thereby reduce the risk of deliberate injury to fish, reduces the intensity of the impacts relating to physiological injury / mortality to medium, the residual impact will reduce to low consequence and be of LOW significance. All other impacts on fish remain of LOW significance. Avoidance effects or behavioural alterations from seismic surveys involving many fish species do not automatically imply risk factors and thus do not necessarily cause a disturbance to the fishery (McCauley et al., 2000). A recent large-scale experiment conducted by Meekan et al (2021) in Australia showed no short-term or long-term effects on the abundance or behaviour of demersal fish assemblages in response to a commercial seismic source. This suggests that seismic surveys have little impact on demersal fishes. Other studies that found no evidence of significant changes in catch rates or fish abundance include Hassel et al. 2004, Picket et al. 1994, Miller and Cripps 2013 and Thomson et al. 2014. Noise modelling was undertaken for the proposed survey and the transmission of sound at various threshold levels was taken into account. In terms of the Russell Report, inputs from the fisheries specialist points to the fact that tuna catches globally were under stress mainly from fishing effort and also due to climate variability. In fact, the data, if interrogated further, shows that the variability in catches in Namibia

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
accepted reason. Activities associated with the Project could further pressure this species by physically harming individual seals, and by disrupting the seals' food supply. 84. The Pisces Report states that Cape fur seals are unlikely to be found in the project area, citing map that shows generalized foraging areas that extend nearly exactly to the edge of the reconnaissance area.[90] However, the report also states, "[s]eals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles (~220 km) offshore,"[91] meaning a large part of the reconnaissance area is well within the foraging range of Cape fur seals. Moreover, the Based on the questionable assumption that Cape fur seals are unlikely to occur within the reconnaissance area, the Pisces Report authors deemed their sensitivity to the proposed seismic operations to be "LOW," in spite of the finding that "The potential impact of physiological injury to seals as a result of seismic noise is deemed to be of HIGH intensity."[92] **Whales and dolphins** 85. There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.[93] 86 The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the	were more associated with operational dynamics of the Namibian fleets and their licensing conditions that had reduced their effort (as South African vessels were not permitted to fish in Namibian waters). Cumulative impacts are assessed in Section 9 of the BA report. For both technical and commercial reasons, it is unlikely that concurrent seismic surveys will be undertaken in the same area during the same survey window. However, the cumulative impacts associated with multiple surveys was assessed and detailed in Section 9.3.5 of the BAR. Section 9.3.5 of the BA Report states that "three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. This relates to the large pelagic long-line sector only, and only in the event that all three surveys are undertaken simultaneously. It should be noted that the seismic industry typically avoids simultaneous surveys occurring in close proximity to each other as this has the potential to degrade the quality of the recorded survey data. Other cumulative impacts are all expected to be low after mitigation is applied – therefore overall cumulative impacts are considered low post-mitigation. It should also be noted that of the three potential surveys cited by the Appellants, the GX Technologies survey should be disregarded as the company went into liquidation in 2022. The appellants' contention that up to 30% of the revenue generated by the impacted fisheries would be lost during the 70 day period is unsubstantiated and vague for the following reasons:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.[94] **Fish** 87. The BAR downplays the impacts of seismic surveys on fish and the fisheries they support, particularly in the case of the large pelagic longline fishery and the tuna pole-line fishery. While the BAR assesses the exclusion of fishing vessels due to temporary safety zones during seismic surveys, it fails to adequately assess the actual impacts of seismic activities on the target fish species themselves, both in the short and long-term. During the seismic survey, fishing vessels would be required to maintain a safe operational distance from the survey vessel and streamer array, which may extend up to 6 nautical miles. The FBAR assessed the impact of potential exclusion for each commercial sector based on the affected area of fishing ground and the amount of catch reported within the Reconnaissance Permit area. Given the location of the Reconnaissance Permit application area, two high-value fisheries are directly impacted: the large pelagic longline fishery (targeting tuna, swordfish and shark) and the tuna pole-line fishery. 88. The FBAR concluded that the Project's activities will result in exclusion to fishing grounds for at least the large pelagic longline fishery. The FBAR states that "[t]here is a high probability that the large pelagic longline sector (targeting tuna, swordfish and shark) will experience loss of access to fishing ground over the duration of the	• The four-month window is proposed to coincide with the period of lowest activities for the fisheries that operate in the potentially affected sectors; • It should further be noted that the survey will not be undertaken over the entire tuna fisheries area or the whole application area at the same time and will thus not lead to a complete shutdown of the fishing activities in the pelagic longline sector during the 70 day period of the survey; and • The mitigation measures included in Section 9.3.2 of the BAR provide for avoidance of the peak fishing periods and, furthermore, for the establishment of clear communication channels to be established with the other users of the survey area and to ensure that the disturbance within this sector is reduced to the absolute minimum. The impact on the affected fishing sectors was assessed to be of low significance and short duration and it could thus not be stated that "The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna." Impacts of cumulative sound exposure on marine mammals are evaluated using disturbance and injury threshold, defined as temporary threshold shifts (TTS) and permanent threshold shifts (PTS) (Southall et al. 2019). The audibility of a noise pertains only to the perception or detection of a sound above background levels of ambient noise. The thresholds established by Southall et al. (2019) are internationally regarded as standard references for environmental impact assessment of underwater noise. Although the modelling report doesn't specifically reference the CBA areas, the purpose of the modelling was to model the likely sound transmission and contours. The outputs of the model were then

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
proposed 70-day survey," and that (t)he impact of exclusion is assessed to be of high magnitude."[95] 89. In terms of noise impacts to the target fish of the large pelagic longline fishery and the tuna pole-line fishery, the Pisces Report acknowledges that "(s)eismic activities have been predicted to possibly affect the migration patterns of tuna leading to substantially reduced catches of albacore and southern bluefin tuna in southern Namibia and the Great Australian Bight, respectively,"[96] yet ultimately the Report concludes that "(a)s there is currently a dearth of information on the impacts of seismic noise on truly pelagic species such as swordfish and tuna (Evans et al. 2018; Webster et al. 2016), links between changes in migration patterns and subsequent catches thus remains speculative."[97] The FBAR thus maintains that potential impact on individual fish behaviour is of MEDIUM consequence and that "the residual impact due to seismic noise is considered to be of LOW NEGATIVE significance for the large pelagic longline and tuna pole-line sectors."[98] 90. Overall, the FBAR concludes that with mitigation (timing of the surveys to avoid peak fishing periods), the following overall impact significance: Based on the combination of extent, duration and magnitude of the impact, and considering the high probability that the impact would occur, the overall significance of the impact is considered to be MEDIUM	considered and assessed by the marine ecology specialist who specifically considered the CBA areas. The Appellants' submission that mitigation measures proposed only focus on marine mammals, is not substantiated by the large number of mitigation measures as detailed in Section 9 and 11.4 of the BAR. The use of infra-red cameras was discussed during the various public meetings held during the BAR review phase and included in the Public Participation Report in Appendix 2. It should further be noted that the Appellants' commented on the lack of inclusion of infra-red cameras during the BAR review phase, and subsequently the EAP included this as a specific mitigation measure in the final BAR. It is therefore strange that the Appellant now disputes the use of this technology and lists this as a supporting factor in this grounds of appeal. The Noise impact on plankton is assessed in Section 9.3.1.1.7 of the BA report. The study by McCauley et al. (2017) generated significant public attention, but the paper has not been widely accepted by the scientific expert community as the findings are considered severely flawed. Details on the independent reviews of the paper are provided in the EnerGeo response to a publication by the Scientific Advisory Group on Emergencies (SAGE). Follow-up studies by Richardson et al (2017) failed to conclusively demonstrate discernible effects on zooplankton biomass on a regional scale and Fields et al. (2019) detected no significant behavioural differences in the copepod species *Calanus*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
NEGATIVE. Due to the low probability of the operations of the tuna pole-line sector within the Reconnaissance Permit area, the overall significance of the impact on the sector is considered to be LOW NEGATIVE. 91. The EIAR fails to adequately assess the vulnerability of the targeted fish species (including tuna and sharks) to noise impacts, and any decision based on it would be unreasonable. This is a major flaw because many of the large pelagic fish and shark species likely to occur in the offshore regions of the Orange Basin are considered globally 'Vulnerable' (e.g., bigeye tuna, blue marlin, Oceanic Whitetip shark, dusky shark, great white shark, longfin mako), 'Endangered' (e.g., shortfin mako, whale shark) and 'Critically Endangered' (Southern bluefin tuna). 92. The impact on fish assemblages is difficult to interpret, due to multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. A global review of the effect of seismic activities on fish and invertebrates acknowledged the limits of the current research due to experimental designs used or due to the focus on single species during investigations. A key concern is a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys that have been previously identified may be reflective of underestimation or overestimation and would depend on the type of interaction (synergistic, additive, or antagonistic).[39] 93. Sounds pollution from seismic surveys may have a wide range of effects on fish species. Exposure to intense sounds can result in mortal injury, but over longer distances issues are associated with sounds that are detectable by fish and which may affect their behaviour, causing them to move away from their migration routes, flee important habitats in which they feed or breed, interfere with	*finmarchicus* based on distance to the source or control vs. exposed groups. The reconnaissance permit area is located far offshore (120 km at its closest point) and therefore beyond the influence of coastal upwelling, which will influence both plankton abundance and the abundance of fish species that depend on plankton as a food source. From Figures 17, 18 and 19 in the marine ecology specialist assessment it is evident that the project area lies well beyond major fish spawning and recruitment area (and therefore zooplankton and ichthyoplankton abundance): Figure 27 shows the area in relation to Cape Gannet and African Penguin distribution; Figure 37 shows the area in relation to seal foraging areas and Figure 47 shows the area in relation to virtual turtle hatchling trajectories. The survey area in relation to various marine mammal distributions is also provided and in all cases it is evident that interaction with marine fauna in those offshore waters should be minimal. The impact assessment shows that these impacts are of a medium-low significance even before any mitigation measures are applied. Regarding the supplementation with respect to the operating hours of the PAM monitoring: This would require the survey to likely run over two (or more) seasons. This is not only not cost effective for the seismic operator, but would extend the duration of the acoustic impacts (and others) associated with surveying. Considering that the survey area is located within the major shipping lanes and that ambient sound levels (dominated by the noise of vessels) will be persistent throughout the day and night, it seems more appropriate to undertake the survey in as

1975

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
their communications, affect reproductive behaviour (where sound is used to attract mates and facilitate spawning), or prevent or mask the detection of other biologically important sounds. Because of these many-pronged effects, seismic surveys can have compounding negative impacts on marine fish. 94. In his expert affidavit filed in a recent seismic survey case,[300] Dr Alexander Claus Winkler provided testimony regarding evidence of direct, lasting behavioural effects of seismic surveys on the rhythmic behavioural foraging patterns of cod in the North Sea. Winkler points out that both hake and snoek perform rhythmic diel foraging migrations off the seafloor at night and onto the seabed during the day. Given that seismic surveys are conducted both during the day and night, it is likely that these benthic fish species will migrate higher up the water column at night, bringing them within distances that may expose them to direct injury and mortality impacts from seismic surveys. It is noted that the Pisces report indicates that species most likely to be found in the area of interest include large migratory fish (such as tuna, billfish and sharks), many of which are considered threatened by the IUCN due to overfishing.[301] 95. In addition, contrary to the **FBAR**'s conclusions that there is only **LOW NEGATIVE** significance for the large pelagic longline and tuna pole-line sectors,[302] a 2018 desktop survey of South Africa fisheries impacts from seismic surveying by Namibian fisheries expert David Russell ("Russell Report") concluded the following: (W)here there are cumulative impacts from repetitive surveys in the same area, as has occurred off Southern Namibia tuna fishing grounds, where	short a time as possible, in which case night-time operations are necessary. The studies undertaken internationally over the past ~70 years on the impacts of noise on marine fauna (of which some 400 peer-reviewed publications have been summarised and cited in the marine faunal specialist study) have concluded that the effects of underwater sounds vary substantially and depend on a wide variety of physical and biological factors. When writing articles on the effects of seismic acquisition on marine fauna it is therefore not difficult to bias the literature cited to either demonstrate detrimental and irreversible impacts or only very limited impacts, depending on the personal view of the author(s) and/or the targeted readership. The marine faunal assessment has made efforts to present published results objectively, and nowhere claims that acoustic surveys do not result in impacts. Injury is likely at very short range, with behavioural disturbance occurring over greater distances. The final significance ratings are determined using information from the peer-reviewed literature together with the noise modelling results (which put the threshold distances from the source array to mortality and potential mortal injury into perspective), adopting the precautionary principle as is required when undertaking such impact assessments, and taking into account the sensitivity of receptors present in southern African waters. Given all of the evidence, the conclusion reached for the various assessments is that impacts are either of low or very low significance. It is not disputed that MMO sightings are not 100% efficient. Various approaches have been adopted over the years to improve observer

catches have severely declined since 2011, and in 2017 dropped off to non-commercial catch rates, there is the ominous possibility that the tunas change their migration path. Environmental factors such as El Nino appear to also have contributed significantly, but combined with regular seismic surveys, the environmental signals are potentially devastating.[303] 96. There is a possibility that up to three seismic surveys (Searcher, TGS, and GX Technologies) would take place simultaneously in the area, which would further increase geographic exclusion of the fishery. If multiple 3D seismic surveys were not undertaken simultaneously, then sequential surveys in the same area would prolong the loss of access to the pelagic longline sector and duration of seismic impacts to fisheries. Yet the FBAR does not directly assess the impacts of simultaneous surveys on the fisheries. 97. The FBAR concludes, without citing any evidence, that after months of up to three simultaneous seismic surveys in the pelagic longline sector, "[o]nce completed there is not expected to be any residual impact."[304] As noted above, the Russell report identified potential long-term impacts of repeat seismic activity on Southern Namibian tuna fisheries, with implications that tuna may change their migration patterns to avoid noise pollution.[305] The BAR fails to adequately consider or mitigate impacts to the pelagic longline sector that are both short-term (potentially closing the fishery for 70 days or longer given multiple surveys in a single year) and long-term (inflicting behavioural and migration shifts).	efficiency, particularly at night, with infra-red binoculars and mast-mounted infra-red (IR) cameras being tested. These have, however, not proven as effective as initially anticipated, due to lack of detectable temperature differences, resulting in the implementation of the 24/7 PAM surveillance. From a seismic operator's perspective, it is not feasible or cost-effective to cease airgun operations at night as this would prolong the duration of the survey possibly requiring multiple seasons to complete the acquisition. This would also add substantially to the overall survey duration and cumulative impacts.

98. The sector had an estimated wholesale value of R124 Million in 2018, or 1.2% of the total value of all fisheries combined. For tuna pole-line, the fishery runs predominantly from November through June, while the large pelagic longline fishery runs highest from May to November.[106] The FBAR lists a proposed window of January – May for its 70-day 3D seismic survey, meaning a large fraction (up to 30% with an approximate wholesale value of R40 Million) of the fishery year stands to be excluded. Because its assessment did not adequately consider the longer-term residual impacts on the fisheries from seismic activity, this monetary loss stands to be much greater than that estimated from fishery exclusion alone. 99. The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna. Such changes in the fishery could have severe and lasting implications for communities dependent on this important fishery for many years to come and should have been included in the impact assessment. 100. The FBAR states that "[t]he zones of TTS [temporary threshold shift] effect for fish species with and without swim bladders are predicted to be within 3.5 km from the survey lines for the 3D survey 24-hour operation scenarios considered."[107] This predicted zone of TTS for fish both with and without swim bladders is a gross underestimation and based on minimal and non-regional specific data, including data from riverine 2D seismic activity on freshwater species (e.g. Popper et al., 2005). As the Capricorn Report admits, "(t)o date there have

been no studies focused directly on the (fish) species found locally."[108] 101. Most of the mitigation measures proposed in the BAR are designed to minimise impacts to marine mammals. As admitted in the Pisces Report, vastly less is known about how such mitigation measures alleviate sound impacts experienced by marine fish species.[109] Large pelagic fish (e.g. tuna, sunfish, or sharks) would not be detected by PAM (which would be tuned for marine mammal vocalisations) and would not likely be detected visually at night by observers or using an infrared thermal imaging camera (since cold-blooded fish, as opposed to warm-blooded mammals, do not have high enough temperature differences from the water). 102. The FBAR further fails to provide evidence that infrared thermal imaging is effective as a mitigation measure. 103. TGS takes no preventative mitigation measures to minimise impacts to marine fish species during 3D surveying and has a single and insignificant mitigation measure (7.1) to shut down seismic shooting in the case the following is observed: "mass mortalities of squid and fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO [marine mammal observer] to be as a direct result of the survey."[110] 104. Although it has been suggested that the sound energy from air guns may harm fish species with swim bladders and those without, there are very few studies directly examining the potential effects on fish physiology or behaviour, and even fewer focusing on pelagic fish species. Unknown impacts are not the same as no impacts, and the

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
precautionary principle should be invoked. There are significant knowledge gaps regarding the impact of 3D seismic surveys on marine fish species, particularly those that would be impacted by the Project. Specifically, there is currently not enough information about the fish species in the area or their response to sound to be able to make any meaningful assessment of the impacts. Therefore, the precautionary approach set out in NEMA suggests that this lack of knowledge should weigh against the proposed 3D seismic surveying in a vital and valuable offshore fishery. **Zooplankton** 105. The FBAR disregards the precautionary approach at every step in the analysis of impacts on plankton, which it concludes does not warrant mitigation measures and will have a medium pre-mitigation impact, yet a very low residual impact.[111] Yet, as demonstrated below, there is a significant concern that the BAR underestimates the impacts of seismic surveys on plankton, which form the base of the ocean food chain. 106. The FBAR does not provide actual data to demonstrate that there is not significant or even medium plankton abundance in the survey area. The BAR "expects" that plankton abundance to be low with seasonal peaks may occur associate with MPAs.[112] Yet, the surveying is meant to have temporal overlap with speak spawning products of commercially important species.[113] 107. Studies by McCauley et al. (2017) referenced in the Pisces Report indicates that seismic blasts may kill various species of zooplankton in Australia at distances of up to 1200 m from an airgun[114], and more

recent research shows lethal and behavioral impacts to zooplankton from airgun discharges.[115] Still, other studies (Fields et al., 2019), report no measured mortality or sublethal effect on copepods at distances >10 m from a seismic blast in Norwegian waters.[116] And other studies (Richardson 2017) found "substantial impact of seismic activity on zooplankton populations on a local scale within or close to the survey area."[117] While noting that zooplankton mortality can be difficult to assess in the field (in situ) and that realistic conditions are very difficult to reproduce in a laboratory setting, nevertheless these highly contradictory results suggest that effects may be variable and highly dependent on zooplankton species and/or marine geographical area. Research should be undertaken to survey the current literature on zooplankton types in the Benguela Upwelling Zone and better link this knowledge to the airgun impacts literature available. The BAR fails to take these steps, making it impossible to assess the impacts of seismic surveys to the zooplankton communities underpinning the food webs that support fish, marine mammals, and fisheries.		
108. As noted, zooplankton forms the base of many important food webs in the marine environment. Depletion of zooplankton could thus have an impact on food for their predators (such as fish) as well as impact fish eggs and larvae (ichthyoplankton) with potential local impacts on species important in fisheries. This damage to zooplankton as found by studies over 1km away (McCauley 2017) and within 15km (Richardson 2017) from the survey array raises concern

that a 500m buffer for other animals that are unable to move away from the sound, is far too small to ensure that damage is not inflicted (even if they were able to evade it).[118] **The proposed mitigation measures are inadequate to prevent unacceptable harm to marine life** Simultaneous Surveys 109. The FBAR proposes the use of a 40 km buffer between vessels during concurrent simultaneous surveys (p. 211) as a mitigation measure, relying on "advice from the US Department of Interior (2014)." The purpose of the buffer is to mitigate "the cumulative impacts of three potential surveys occurring concurrently."[119] The 40 km buffer mitigation measure, first proposed in the United States, originally purported to avoid harassment of marine mammals during simultaneous surveys. This was expected to be achieved through a distance between vessels that would provide a corridor where "airgun noise is below [harassment] thresholds and approaching ambient levels such that animals may pass through rather than go larger distances to go around the survey vessels."[120] However, the mitigation measure neither provides a corridor below harassing levels of acoustic noise for marine mammals between vessels seismic surveying, nor does it mitigate cumulative impacts as portrayed in the FBAR. In fact, the mitigation measure is not even used in the US, making the FBAR reliance upon this measure deeply flawed. 110. First, the 40 km buffer is based upon a threshold of 160 dB for harassment, a standard that the U.S. government has since abandoned as appropriate to provide adequate protections. For

example, the US government found in 2018 in reviewing harms to marine mammals during oil and gas geophysical surveys that, "[s]tudies of marine mammals in the wild and in experimental settings do not support" use of a single 160-decibel threshold and that "that an approach reflecting a more complex probabilistic function is better reflective of available scientific information," because it "takes the fundamental step of acknowledging the potential for . . . harassment at exposures to received levels below 160 [decibels]."[121] 111. Second, as noted above, scientists recognize that this 160 decibel threshold is not supported by science. In addition, in his expert declaration Dr. Nowacek noted that "seismic surveys can disrupt important behaviors in baleen whales at exposure levels far below the 160 dB threshold".[122] 112. Third, the application of a 40 km buffer as a wholesale solution for simultaneous surveys is incompatible with even the 2014 Department of Interior document that the BAR is relying upon. In fact, the US Government prohibits the use of a 40 km buffer as a general mitigation measure. It instead found that new science demonstrated that "airgun noise can be detected at great distances from the sound source, such as across ocean basins," and that therefore, the mitigation measure must be considered in the site-specific context and include any new information at the time as well as "any potential aggregate effects from existing permitted

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
surveys."[123] The BAR does none of this analysis and in fact proposes potentially reducing the buffer zone.[124] 113. This mitigation measure has been proven to be scientifically unsound and ineffective and uses an approach inapposite with the base documents upon which the BAR relies, inconsistent with the current practice of the US Government, and inconsistent with the science. Therefore, there is no basis for the BAR to conclude that a 40 km buffer will mitigate cumulative impacts of concurrent seismic surveys. Inefficacy of Proposed Mitigation Measures 114. Several of the proposed mitigation measures are ineffective to mitigate the harms related to the impacts of the seismic surveys. Consequently, the significance of the post mitigation impacts are understated, exposing marine species, in particular marine mammals and to more injury and harm than indicated in the conclusions of the BAR. 115. Soft Starts and Ramp Ups: Harris *et al.* found that the soft starts are "are likely to reduce the impact for highly mobile large animals, this is unlikely to be adequate for the many species that are prevalent in the area over the austral summer months and are unable to avoid the array or leave the area due to their lower mobility, such as smaller turtles, penguins, invertebrates, some fish species and zooplankton."[125] Moreso, Dr. Nowacek found that soft starts or ramp ups do not protect highly mobile cetaceans, finding them "inadequate to protect cetaceans present year-round or deep-diving

beaked whales."[126] Dr. Nowacek further expounded "there has been no experimental confirmation that this procedure is broadly effective at reducing overall exposure."[127] In considering a situation where soft starts or ramp ups worked perfectly, Dr. Nowacek found that "this mitigation measure would reduce only the number of injuries incurred in the vicinity of the seismic vessel and does not address at all the larger body of effects."[128] 116. Observers: Harris *et al.* explain that visual observers, although important to mitigation, have deficiencies, which brings into question the EAR's conclusions regarding the level of impacts post-mitigation: *"The finding of observer efficiency (from a scientific monitoring study conducted during the 2018/19 and 2019/2020 seasons on the humpback whales on the east coast) suggests that even with trained observers up to 44% of humpback whales in an area went undetected. This casts doubt on the effectiveness and success of Marine Mammal Observer (MMO) sightings of the largest species (humpbacks) as a mitigation measure, indicating that it is most likely that whales go undetected. Furthermore, the detection rate for smaller species, such as dolphins, seals, turtles and flightless birds (penguins), would be expected to be much lower, obviating the effectiveness of visual observations to prevent harm to these species."*[129] 117. Dr. Nowacek reiterates that the mitigation measure of visual observers is "inadequate to protect cetaceans present year-round or deep-diving beaked whales."[130] Dr. Nowacek further explains that the use of visual observers to detect whales "is imperfect at best"

because low light and other poor visibility conditions (such as fog or high-sea states) impair the ability to spot whales and, as Dr. Nowacek goes into further detail, even in ideal conditions it is very difficult to spot whales.[131] This is echoed by Harris et al. stating the "efficacy of a MMO is likely to be low due to the nature of the offshore marine environment in the survey area (frequent high swells and winds affecting surface visibility), putting species who are missed by MMOs and PAM operators at extreme risk, particularly at night or during adverse weather conditions."[132] 113. Passive Acoustic Monitoring (PAM): Harris et al. discuss how "the reliance on observers to do visual sightings to supplement the PAM monitoring during the day, as a mandated mitigation measure, necessitates questioning the acceptability of continuing with survey activities at night. If the visual observations are useful (perhaps sighting large animals around 65% of the time) in addition to PAM, then relying on PAM alone at night cannot be an effective mitigation measure. The authors express the opinion that surveys should not occur between sunset and sunrise each day if a real attempt of maximum avoidance of cetaceans is the objective of this mitigation measure."[133] 114. Dr. Nowacek discusses as well the limited benefit of PAM. With PAM, "whales will not be detected even when present if they are quiet or not vocalizing or if background noise is too high." Dr. Nowacek also noted that "studies show that baleen whales cease vocalizing in the presence of even low levels of seismic survey noise."[134]

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
120. The FBAR's attempts to address this shortcoming in mitigation by equipping MMOs "with infra-red cameras in order to observe mammals at night."[135] However, this is an undeveloped technology for spotting cetaceans. It is not reliable, so much so that it is not typically used by scientists as part of their surveys. Further, there are questions with the scope of view, range/distance, as well as the impact of conditions on the ability to use the technology. In short, it is encouraging to bring new technologies to the table, however it requires more testing and improvement before it could be considered suitably reliable and certainly before it could be factored into the the mitigation of harms to cetaceans. **Lack of baseline noise assessment** 121. The FBAR fails to establish an acoustic baseline assessment of the area, and furthermore fails to present a plan to conduct an adequate baseline noise assessment. As part of its recommendations to minimise impacts to marine fauna, the BAR lists: Baseline noise measurements can provide useful information (prior to operations) when interpreting underwater noise predictions for the introduction of a new noise source. As such, it is recommended that underwater noise measurements be implemented that would include the deployment of underwater sound monitoring equipment to establish an actual baseline prior to the commencement of the survey and then operational levels of noise during the survey.[136] 122. The FBAR provides no guidance for the recommended baseline noise measurement, including the duration of monitoring period, or a

range or frequency for detection. This lack of detail means it remains impossible to assess if this mitigation step would meet best practice standards such as those put forward by the Marine Mammal Observers Association. 123. The current lack of a baseline assessment means that the ambient background noise considered in the noise modelling falls short of best practices. Best practice acoustical modelling entails collecting site-specific data to calibrate acoustic models that can then be applied to characterize acoustic exposure of marine fauna in a given study area.[137] **Chronic Noise Impacts** 124. The seismic survey's airguns consist of 24 active airguns that will blast sound loud enough to penetrate the seabed floor every 6-20 seconds, 24 hours a day, for 70 days. Each acute blast will create direct harms to marine species. In addition, besides the direct harm that the pulse will create, the repetitive blasting will increase ambient noise, even at a distance of 100 kilometres.[138] These two factors expose marine species to chronic noise impacts over a large distance, as the sound travels hundreds and even thousands of kilometres.[139] The FBAR fails to take into account the increased stress and behavioural impacts that this chronic noise will cause on marine species in the area of seismic surveying and beyond

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Ground 3: Failure to adequately assess cumulative impacts 125. Below is a map detailing the updated categories of Oil and Gas concessions along the entire coastline of South Africa:  Information received from Petroleum Agency SA, in line with a PAIA Request submitted by the Legal Resources Centre on 12 October 2022 126. In addition to the abovementioned map, it is noted that the BAR acknowledges that should other seismic survey campaigns be undertaken concurrently with TGS's proposed survey programme, cumulative impacts may be likely and there would be a need for alignment in planning of such concurrent operations to reduce	It is understood that ION GXT has been declared bankrupt and have ceased operations - as such, the ION GXT Reconnaissance Permit is considered to be defunct. Section 9.3.5 of the BA Report states that "three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. This relates to the large pelagic long-line sector only, and only in the event that all three surveys are undertaken simultaneously. It should be noted that the seismic industry typically avoids simultaneous surveys occurring in close proximity to each other as this has the potential to degrade the quality of the recorded survey data. Other cumulative impacts are all expected to be low after mitigation is applied – therefore overall cumulative impacts are considered low post-mitigation. The marine faunal assessment has made efforts to present published results objectively, and nowhere claims that acoustic surveys do not result in impacts. The inference is that, for these whale populations, there is no direct evidence to link the long-term negative change to population size directly to seismic survey activities. The statement is only one regarding the "lack of evidence" with respect to certain whale populations and seismic surveys. The marine fauna report recommends planning seismic surveys to avoid sensitive areas and periods for some marine fauna: Movement of migratory cetaceans (particularly baleen whales) from their southern feeding grounds into low latitude waters (June/July and late October/November), and their aggregation on the summer feeding grounds between St Helena Bay and Dassen Island from late October to late December and ensure that migration paths are not blocked by seismic operations. If possible, the survey should be undertaken from	

Initials

1989

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
cumulative noise impacts to an acceptable significance.[140] The draft BAR notes that there are two current pending applications with PASA (Searcher Geodata and GX Technology Corporation) which both overlap the proposed TGS 3D seismic survey area, as depicted in the diagram below:	North to South to avoid these feeding aggregations. A discussion of the migration of various cetaceans is provided in Section 8.4.3.6 of the BA Report. It is unlikely that concurrent seismic surveys will be undertaken in the same area during the same survey window however the cumulative impacts associated with multiple surveys needs to be, and was, assessed. The decision-making authority did elaborate on the decision regarding whether concurrent surveys can take place. The proposed seismic activity will not automatically lead to further exploration, production, and utilisation of petroleum resources. The information to be obtained through the seismic survey will provide information as to whether they may be exploitable resources. The climate change impacts of any potential future exploration or production activities would have to be assessed as part of the associated and required Environmental Authorisation applications submitted for those projects, with due consideration of the other climate affecting activities proposed or in place at the time.

1991

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
concurrently needs to be considered. The FBAR thus includes a cumulative assessment which assumes that the three surveys (Searcher, TGS and GX Technologies) occur simultaneously during the summer survey window in 2022/23. In this event, the draft BAR indicates that: 128. Associated impacts to marine fauna would be of high intensity and extend regionally, over the short-term (assuming they take place over the same summer survey window). The impact consequence for cumulative surveys is therefore considered medium. 129. Concurrent activities could also add to the cumulative impact on fisheries. Simultaneous survey operations would result in an increase in the extent and magnitude of the impact on the large pelagic longline sector. The impact duration would remain unchanged. Three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of **medium negative significance** on the large pelagic longline sector, both with and without the application of mitigation measures. 130. Curiously, the BAR impact table[141] combines cumulative impacts on marine fauna and fisheries and rates the pre-mitigation environmental significance as 'medium' and the post-mitigation impact as 'low'. This does not reconcile with the preceding paragraphs which indicate with regard to cumulative impacts of three concurrent seismic surveys, an impact of medium negative		

[141] At p236.

Initials

1992

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
significance on the large pelagic sector could be expected 'both with and without the application of mitigation measures. 131. The Final BAR states regarding confounding and cumulative effects that the assessments of impacts of seismic sounds provided in the scientific literature usually consider short-term responses at the level of individual animals only, as the understanding of how such short-term effects relate to adverse residual effects at the population level is limited. The report goes on to state that data on behavioural reactions to seismic noise acquired over the short-term could, however, easily be misinterpreted as being less significant than the cumulative effects over the long-term (i.e. what is initially interpreted as an impact not having a detrimental effect and thus being of low significance, may turn out to result in a long-term decline in the population, particularly when combined with other stressors such as temperature, competition for food, and shipping noise). The report notes that confounding effects are, however, difficult to separate from those due to seismic surveys.[142] 132. The report also states that the potential cumulative impacts on individuals and populations as a result of other seismic surveys undertaken either previously, concurrently or subsequently are difficult to assess. The report indicates that a significant adverse residual environmental effect is considered one that affects marine biota by causing a decline in abundance or change in distribution of a population(s) over more than one generation within an area. The report makes reference to numerous 2D and 3D seismic surveys having been undertaken off the West Coast over the past 17 years, and relies on reported increases in the southern right whale and humpback whale populations over a time when seismic surveying frequency has increased as *'suggesting that, for these populations at*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPELANT	COMMENTS BY THE DMRE/PASA
least, there is no evidence of long-term negative change to population size as a direct result of seismic survey activities'.[143] The assumption made that an increase in whale populations suggests that there is no evidence of long-term negative change to population sizes as a direct result of seismic activities, is questionable. This is an assumption that cannot be inferred from the facts (the increase could be as a result of any number of other external factors). 133. It cannot simply be assumed that the lack of evidence of long-term negative population changes as a direct result of seismic survey activities means that there are no negative impacts (including potentially significant impacts). In their report relating to the TOSACO EIA appeal, Harris *et al* point out that although the humpback whale population is increasing, there is evidence to suggest that cetaceans in South African waters are being affected by changes in their ecosystem and it is not well understood yet what is driving these changes and what the long terms effects could potentially be to populations.[144] Concerns noted in the report include an observed decrease in southern right whale calving success of the South African population and a strong link between foraging success and reproduction.[145] They suggest an investigation into possible decreases and/or spatial or temporal shifts in their prey availability at higher latitudes due to environmental variability. They also highlight a concern of the continued low numbers of unaccompanied adults

along the South African coast which could potentially have serious consequences for cow-calf pairs in relation to the country's whale-watching industry in the future. 134. The BAR states that in the 'unlikely' event that multiple surveys would take place at the same time within the same survey area, 'the risk of cumulative noise impact must be considered and is suggested to be managed'. The BAR suggests that mitigation should include maintaining a distance of at least 40 km between survey vessels 'until sufficient objective evidence is obtained that a reduced buffer distance is acceptable'. Where this 40 km buffer distance cannot be maintained, the FBAR suggests that each of the additional activities to those described in the technical noise report should be modelled or otherwise considered in terms of the cumulative noise level and with reference to the criteria described in the report.[345] 135. However, as referred above at paragraphs 109-1113, the US Government prohibits the use of a 40 km buffer as a general mitigation measure and therefore, the mitigation measure must be considered in the site-specific content and include any new information at the time as well as "any potential aggregate effects from existing permitted surveys. This mitigation measure has been proven to be scientifically unsound and ineffective and uses an approach inapposite with the base documents upon which the BAR relies. Therefore, there is no basis for the BAR to conclude that a 40 km buffer will mitigate cumulative impacts of concurrent seismic surveys.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
136. Given the lack of certainty regarding cumulative impacts of concurrent 3D seismic survey areas, a risk averse and cautious approach should be applied by not authorising concurrent surveys and suggests that should the decision-maker ought to have refused granting the environmental authorisation. 137. In addition, the FBAR does not consider the cumulative impacts of other proposed offshore oil and gas seismic surveys, exploration and production in other Blocks within South Africa's exclusive economic zone. Having regard to the global Climate Emergency[147] and South Africa's international commitment[148] to *'working with others to ensure temperature increases are kept well below 2°C above pre-industrial levels, which could include a further revision of the temperature goal to below 1.5°C in light of emerging science'*[149] by reducing greenhouse gas (GHG) emissions, TGS's proposed 3D seismic survey would, if additional commercially viable resources are identified and developed through to production phase, inevitably add to South Africa's overall GHG emissions (South Africa's energy sector currently contributes an estimated 84% percent to the country's overall GHG emissions).[150] As a reasonably foreseeable future impact that may become more significant, especially in combination with impacts arising from similar offshore oil and gas exploration and

production activities, it is submitted that the cumulative impacts[151] of such GHG emissions need to be identified and assessed.		
Ground 4: Failure to conduct meaningful consultation with communities and local people (and in particular small-scale fishers), within the public participation process, including the Social Impact Assessment process 138. It is one of the foundational principles of NEMA that the participation of all interested and affected parties must be promoted and the participation of disadvantaged people must be ensured.[152] Section 24(4)(a)(v) of NEMA provides that interested and affected parties must be given a reasonable opportunity to participate in the environmental impact assessment process. Regulation 41(6) provides that the public participation process must be facilitated in a manner that provides all potential interest and affected parties a reasonable opportunity to comment on the proposed project. Regulation 41(2) of the EIA Regulations requires that the public participation process take into account the relevant guidelines. The 2017 Public Participation Guidelines provide that: 137.1. The level of public participation must be informed by the characteristics of the potentially affected parties.[153] 137.2. The method of communication must be an effective method that will easily reach the intended audiences.[154]	It is our opinion that the Public Participation Process was conducted in line with and exceeded the requirements of the Environmental Impact Assessment (EIA) Regulations (2014), as amended, and that the process followed was reasonable. With reference to Section 7 and Appendix 2 of the BA Report, EIMS has undertaken the public participation and consultation processes in accordance with the requirements of the NEMA EIA Regulations. This process included notification and communication in three different languages, via Radio and Newspaper advertisements, site notices, posters, and direct notification; as well as public and focus group meetings within the potentially affected communities. Opportunity was provided to review and comment on the BA Report and associated documentation to be submitted to the decision maker. It should further be noted that detailed consultations with community members and leadership were conducted by the Social and Heritage Specialists to obtain the views of project affected communities and the potential social and heritage impacts of the proposed project. The applicant is not aware of any additional requests received from I&APs for further avenues or opportunities for	

[151] 'Cumulative impact' is defined in the NEMA EIA Regulations as follows: "in relation to an activity, means the past, current and reasonably foreseeable future impact of an activity, considered together with the impact of activities associated with that activity, that in itself may not be significant, but may become significant when added to the existing and reasonably foreseeable impacts eventuating from similar or diverse activities.

[152] NEMA, section 2(4)(f).

137.3. The language used must provide all potential interested and affected parties a reasonable opportunity to comment without unnecessary difficulty.[155] 139. The court in *Sustaining the Wild Coast NPC*[156] has upheld this and stated: "Meaningful consultation entails providing communities with the necessary information on the proposed activities and affording them an opportunity to make informed representations"[157] 140. Coastal communities and the general public have been overwhelmed with the number of offshore oil and gas related applications running in parallel processes, particularly those which may impact the south-west and west coast of South Africa. In the month of May, I&APs have been called upon to respond to no less than four offshore oil and gas EIA processes, without taking into account legislative public participation processes for the Upstream Petroleum Resources Development Bill and the draft Marine Spatial Plans during a similar period. The EAP in the current application, SLR, has been appointed to conduct three of these parallel EIAs. 141. The table below sets out the various EIA processes, in which it is clear that multiple public meetings and submission dates are running during similar time periods:	participation. The public participation requirements and obligations of the NEMA EIA Regulations has been complied with. With Reference to the table presented in point 141 above, it should be noted that EIMS was the EAP and it is unclear whether this comment relates to this application. However, it should be stated that it is clear that the TGS process did not conflict with other concurrent processes and it is anticipated that I&APs had sufficient time to attend the extensive public consultations undertaken during the initial call to register phase, as well as the BAR Review period. Please refer to the Public Participation Report in Appendix 2 of the BAR for further details on the public consultations undertaken. It should be noted that the Ms Mostert was specifically identified as a key Interested and Affected Party (I&AP) and included in the Public Participation throughout the Basic Assessment Process. Ms Mostert's comments were captured in the minutes of the meetings included in Appendix 2-6 and 2-9 of the BAR. As requested during the public meetings, the final BAR was also made available on the EIMS website (and the datafree version thereof) post submission of the final report to the Competent Authority for adjudication and was available throughout the appeal notification period. The EAP therefore, utilized the reasonable and requested methods of communication and transparency and did not receive requests for alternative methods. It is also important to consider that the findings of the BAR were that there is unlikely to be significant adverse impacts. With reference to Section 7 and Appendix 2 of the BA Report, EIMS has undertaken the public participation and consultation processes in

Project	**EAP**	**Public Participation Meeting Dates**	**Comment/Appeal Due Dates**	accordance with the requirements of the NEMA EIA Regulations. This process included notification and communication in three different languages, via Radio and Newspaper advertisements, site notices, posters, and direct notification; as well as public and focus group meetings within the potentially affected communities. Opportunity was provided to review and comment on the EA Report and associated documentation to be submitted to the decision maker. It should further be noted that detailed consultations with community members and leadership were conducted by the Social and Heritage Specialists to obtain the views of project affected communities and the potential social and heritage impacts of the proposed project. The public participation requirements and obligations of the NEMA EIA Regulations has been complied with. The recommendation of the SIA is that, should the project be approved a representative from TGS must consult with leadership of the community to determine how the communities should be consulted with in future – that is, what is the way the community members prefer to be consulted with for provision of commencement notification and/or daily updates to advise on survey schedules, communication in respect of the proposed research outcomes, etc. The recommendation to include further consultation as part of the conditions of authorisation intends to ensure that the consultation process goes further than just the EIA process, but is continued throughout the entire process, regardless of the outcome. This will assist communities and people on the ground to make informed decisions about technical matters. The intention of the recommendation is not for this condition to be suspensive or determinant on the ultimate decision but rather to function as an additional management/ mitigation measure to be implemented post approval to reduce the significance of the identified impacts and further enhance the community engagements

Karpowership Saldanha. power generation from gas	Triplo4 Sustainable Solutions	October / November 2022	13 December 2022	during implementation, should the project be implemented. The SIA specialist has made a reasoned opinion that the project can be approved on the basis of the outcomes of the consultations already undertaken. Communities are diverse and there are community members who are supportive of this type of development, as much as there are community members against the development. Communities were asked to suggest mitigation measures that the specialists should consider, and this influenced some of the recommendations made in the SIA. All perspectives were considered during the EIA process and the social impact analysis.	

142. Many members of the public will be confused by the various applications, with different processes, slightly different due dates, slightly different applicants all being branded the same with the same EAPs conducting similar EIA processes. It is inconceivable that affected coastal communities are able to respond to each of these processes in a meaningful way. This means that fishers must fish for a living, requiring them to be out at sea daily or for extended periods of time. Even if they wish to do so, they do not have the time or resources to attend multiple public meetings, engage with voluminous technical information, provide comments, ascertain whether their comments have been addressed in comments and response reports, and thereafter proceed to draft appeals. The result, even if unintended, is that those who have less resources, who are required to be out at sea to make their livelihoods, and/or who are unable to fully understand the different proposals and processes, are not able participate and engage meaningfully. The chilling effect is that they are significantly prejudiced by the onslaught of applications

143. There are many people, particularly those such as small-scale fishing communities and co-operatives who will be impacted by the project, who do not have access to the resources and expertise required to access, consider and comment on the records relating to the project, which are voluminous and technical in nature. The current estimate is

The SIA report makes detailed recommendations about further engagement with the communities, and other mitigation and management measures. The mitigation and management measures should be considered in its entirety within the context of the report. Efficient engagement with a community involves more than merely setting up a meeting and inviting people. In many communities there is an expectation that outsiders should enter the community via the leadership before a community meeting can take place. TGS needs to determine what the most appropriate way would be to interact, and this may differ between communities, in order to engage with the individuals and communities in a decolonised way. Once this is done, TGS can proceed with engaging with the communities as a whole in an appropriate way. Education is suggested as a mitigation measure to empower community members to make informed decisions where they are in a position to weigh up the pros and cons for themselves, as was requested by community members during the public meetings. The updated conditions (omissions) referred to were included for clarity.

The Appellants assertion that the voices of the communities have not been heard by virtue of the inclusion of conditions requiring that ongoing engagements, education and collaboration is unfounded. The purpose of these measures was to ensure that there were ongoing

that around 136 unitary entities could be defined as 'communities' under the proposed community based rights allocation system. In the Western Cape and Northern Cape in particular, these settlements can seldom be described as 'communities' in the sense of small, spatially defined geographic units with a homogenous social structure and shared norms.[154] This is not recognised nor considered in the BAR or SIA in that the reports appear to limit their analysis by failing to consider the intricate social structures and norms within these "communities" thereby considering these communities as homogenous and disregarding their unique characteristics. 144. We attach hereto a letter from Carmelita Mostert, marked **Annex B5**, which was also separately sent to the Appeals Authority, which clearly sets out opposition to the seismic surveys based on the impact on fisheries, and points out their difficulties associated with having to find hardcopy reports and with having to consider how her community's comments have been considered by the EAP. 145. To ensure access to a reasonable, adequate and fair public participation process, TGS and their appointed EAP should have used reasonably distinctive and appropriate alternative methods to inform and educate affected communities and small-scale fishers of the significant adverse impacts that this project could have on them. Running a public participation process during time period could not achieve meaningful and effective consultation.	interaction, communication and feedback regarding the operational aspects. The EAP has conducted the impact assessment on the basis of the activities proposed by the applicant. Any subsequent authorisation would be restricted to these specifically assessed activities. Should the applicant or other applicants wish to undertake any additional exploration activities which are not addressed in the current Environmental Authorisation (EA) application, there would be a consequent need to apply for the relevant permissions. These would include a formal application for an Exploration or Production Right as well as a new EA. The impacts of such proposed activities would consequently require specific assessment and public consultation prior to approval. It is premature to assess the likely impacts of further invasive exploration activities or production activities as the extent, duration, location, and magnitude applicable to these activities are unknown at this stage. The NEMA EIA Regulations make a clear distinction between the reconnaissance, exploration, and production activities in that these are listed as distinct and separate listed activities. There is provision in law for these activities to be assessed on their merits as and when they are proposed.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
146. The BAR included a Social Impact Assessment (SIA) that noted[159] that communities feel that there were significant gaps in the available data, and that from a social perspective the non-technical or social risks can potentially cause significant impacts. The report highlighted that potential social impacts identified included: • Uncertainty; • Further marginalisation of vulnerable groups; • Concerns about cumulative impacts; • Impact on livelihoods; • Impacts on sense and spirit of place; • Impacts on social license to operate; • Stakeholder fatigue and disillusionment; • Community expectations; and • Social unrest. 147. These impacts are rated in the final BAR as being of high or medium significance prior to mitigation, and as being medium significance post-mitigation.[160] 148. The report further pointed out that seismic reconnaissance projects are controversial in South Africa, and that while for many stakeholders it is an emotional matter, for others the potential of

impacting on their livelihoods is the biggest fear. The report indicates that some stakeholders feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change, while other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. The expert describes this as a 'complex and wicked problem'.[161] 149. The report went on to state that from a social perspective, it is clear that the communities and the majority of local people are opposed to the project, and that because the project does not happen in a social vacuum, the social environment is much wider than the footprint of the project. The report states further that: *If the social risks and potential damage to cultural and indigenous rights are considered the impact on the social fabric of already vulnerable communities may be significant. At this stage communities feel that they cannot make informed decisions.*[162] *(emphasis added)* 150. Curiously, while this TGS SIA is almost identical to the SIA submitted in the Searcher draft BAR (ref. 1518), the TGS version omits the following sentence from the above paragraph:		

[161] Ibid, p8. In a footnote to the TGS final BAR, a 'wicked problem' is indicated as *'a problem that is difficult or impossible to solve because of incomplete, and changing requirements that are often difficult to recognise'*.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
154. The Appellants submitted in their comments on the draft BAR that recommending that the project proceed subject to meaningful consultation being undertaken – and included as a mitigation measure in the environmental authorisation and implemented prior to the commencement of the 'actual survey' – is highly irregular within the context of an environmental impact assessment.[146] There is no legal basis for meaningful consultation to be undertaken after an environmental authorisation is granted, and including such a recommendation as a condition of authorisation undermines the regulatory scheme for prior impact assessment that is subjected to public consultation. 155. Notwithstanding the above mentioned submissions, the environmental authorisation ("EA") approves the BAR and EMPr, and indicates that it is mandatory for the holder to implement all the recommendations and management measures stipulated in the EMPr throughout all phases of the proposed activities.[147] The EA also stipulates as a specific condition that a community engagement protocol that is based on the San Code of Research Ethics be developed, in consultation with the affected communities and must include a community strategy and grievance mechanism.[148] The EMPr in turn includes as mitigation measures various recommendations under the heading 'Socio-Economic Considerations', all of which are indicated as to be implemented 'Prior to Operation and ongoing'.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
156. The Appellants submit that notwithstanding the public participation processes conducted during the BAR and the SIA processes (which the appellants submitted in paragraphs 115- 121 above, were not adequate or meaningful), it is clear from the SIA that communities and the majority of local people are opposed to the project and that seismic survey companies do not have a 'social license to operate'. The SIA indicates that *'If TGS...wants to proceed with the project, they will need to engage in meaningful conversation with the communities and try to restore relationships. From a community and social risk perspective this is not negotiable'.*[169] The inclusion of mitigation measures in the EMPr (and by reference the EA) fails to adequately take into account the needs and values of the communities (and small scale fishers) who are opposed to the seismic survey.[170] Their voices in opposition to the seismic survey remain unheard in the final BAR and EA. Furthermore, it is submitted that the mitigation measure that TGS should (prior to the operation and on an ongoing basis) *'consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in the future'*[171] cannot be a substitute for meaningful consultation with communities and local people during the EIA process. It is submitted further that such an approach violates the principles of fair administrative decision-making and the right of interested and affected communities to be meaningfully consulted prior to a decision on authorisation being made, and is inconsistent with section 2(4)(f) of NEMA, which stipulates that the participation of all interested and affected parties in environmental governance must be promoted, and all people must have the opportunity to develop the		

[169] TGS SIA, p107.

[170] Section 2(4)(g) of NEMA requires that decisions must take into account the interests, needs and values of all interested and affected parties, and this includes recognising all forms of knowledge, including traditional and ordinary knowledge.

understanding, skills and capacity necessary for achieving equitable and effective participation, and participation by vulnerable and disadvantaged persons must be ensured. 157. The Appellants also note that the SIA states further that the seismic survey industry should reassess their position and social license to operate as an industry in the South African context and should conduct a strategic environmental assessment of the impact of the industry.[172] Notwithstanding this, the report makes a one-sided assumption that the discovery of commercially exploitable fossil oil or gas resources would be beneficial to the economic development of South Africa: *'Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed'*.[173] The Green Connection and Natural Justice submit that the SIA should have reflected the many negative socio-economic impacts that could or are likely to manifest should commercially exploitable reserves be found and developed through to production and use (including but not limited to the socio-economic costs of climate change[174]). 158. In light of the above, the Appellants submit that the public participation process, including the SIA conducted, did not constitute meaningful consultation with communities and local people (and in particular small-scale fishers), and that the mitigation measures requiring further consultation after the EIA has been conducted and a

decision on authorisation made (but prior to the operation and ongoing thereafter) does not cure this flaw in the EIA process. As a consequence, it is submitted that the EA should be overturned on appeal.		
Ground 5. The FEAR does not contain a proper and objective assessment of the negative impacts of the project on people's human rights 159. Small-scale or subsistence fishers in coastal communities heavily rely on local fish populations for their livelihood and cultural practices. If seismic surveys lead to a reduction in fish stocks, it can have negative consequences for these fishers. They may experience reduced catch rates, economic losses, and disruptions to their traditional fishing practices. Furthermore, the cultural and heritage aspects tied to fishing may be undermined if fish populations decline significantly, as it can impact the intergenerational transmission of traditional knowledge and practices. 160. To better understand the correlation and potential impacts, comprehensive scientific studies and assessments are necessary. These studies would need to evaluate the specific local conditions, fish populations, and cultural contexts of the coastal communities in question. 161. Mitigation measures that are proposed within the EMPr, the specialist acoustic studies, socio-economic impact studies and	Section 9.3.3.1 of the BAR in dealing with the cultural heritage impacts, details the following: "The cultural heritage and living heritage related to the communities linked to fisheries and ocean subsistence and further identifying as indigenous communities can potentially be impacted by the proposed project. This impact is indirect and is in the community perceived to be primarily linked to their economic existence as a result in the loss of fishing yield." The Marine Ecological Assessment and the fisheries impact Assessment did not find that there would be a significant impact fishing activities as a result of the proposed seismic survey. As a result, the assumption by the Appellant that there would necessarily be an impact on the cultural practices, is questioned. It should further be noted that the specific local conditions, fish populations, and cultural contexts of the coastal communities in question were considered as part of the BAR as detailed in the Section 8 and 9 and Appendix 3 of the BAR. It is not disputed that the "small-scale or subsistence fishers in coastal communities often have deep cultural and heritage associations with fish and the marine environment. Their practices, traditions, and identity are intertwined with these resources." The impacts identified and the mitigation measures proposed in the Cultural Heritage Assessment and Social Impact Assessment, made it clear that the direct impact on fish populations was considered in detail and highlighted the cultural and heritage significance of fishing. Based on the findings of these studies and as detailed in the BAR, it was the	

Initials

2008

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
heritage impact studies such as adjusting survey timing and locations, implementing exclusion zones, and using sound mitigation technologies, can help reduce the potential negative impacts of seismic surveys on marine life. However, when it comes to the cultural and heritage associations of fish and the broader marine environment, proposing the above mentioned mitigation measures which solely focus on reducing direct impacts on fish populations, may fail to address the complex nuances and broader concerns.[175] 162. Small-scale or subsistence fishers in coastal communities often have deep cultural and heritage associations with fish and the marine environment. Their practices, traditions, and identity are intertwined with these resources. Simply mitigating the direct impact on fish populations may not adequately address the cultural and heritage significance of fishing. Preserving cultural practices, traditional knowledge, and the social fabric of coastal communities requires a more holistic approach that recognizes and respects their unique relationships with the marine environment. 163. Small-scale or subsistence fishers in coastal communities understand through their indigenous knowledge of fishing, that the marine ecosystem is capable of sensitivity to outside interferences. As fishers, they have observed that even the slightest interference with the sensitive marine ecosystem will have an impact on every fish in the ocean, and as a result their livelihoods. Plankton, for example, are the most sensitive to any interferences which indirectly have implications for the larger fish species that feed on plankton. Scientific experts have confirmed in their expert assessments that it is likely that the sound blasting in the ocean caused by seismic	opinion of the specialists and the EAP, that the there are no environmental fatal flaws that should prevent the proposed project from proceeding, provided that the recommended mitigation and management measures are implemented. Based on the nature and extent of the proposed project, the local level of disturbance predicted as a result of the reconnaissance activities, the findings of the specialist studies, and the understanding of the significance level of potential environmental impacts, it is the opinion of the EIA project team and the EAP that the significance levels of the majority of identified negative impacts can generally be reduced to an acceptable level by implementing the recommended mitigation measures and the project should be authorized. Consequently, and with due consideration of the mitigation measures recommended by the Cultural Heritage and Social Impact Assessments, it was the opinion of the Applicant and the EAP that the proposed survey will not detrimentally affect cultural practices, traditional knowledge, and the social fabric of coastal communities. Specific mitigation measures that point to the robust consideration of the human rights aspects identified in the BAR include the following: • TGS should develop a community engagement protocol that is based on the San Code of Research Ethics. This should be done in consultation with the affected communities. This should include a communication strategy and grievance mechanism. • TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. • Consult with communities on potential ways in which to make a positive contribution to the communities.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
surveys will impact on the behaviour of plankton decreasing the number of plankton in the water.[176] Furthermore experts are of the opinion that seismic testing will have a significant adverse impact on numerous species of marine fauna, including endangered and vulnerable species located in the exploration area, and zooplankton.[177] 164. Mitigation measures that solely focus on addressing direct impacts on fish populations may not be appropriate for effectively addressing the indirect and cumulative effects on the broader ecosystem/ecocentric based cultural and heritage rights associated with fishing. Eco-centric based cultural and heritage rights are rights that can be defined as rights that acknowledge that ecosystems, species, and natural elements have their own rights and should be respected and preserved for their inherent worth, beyond their instrumental value to humans. Within this framework, cultural and heritage rights are understood in relation to the natural environment. Ensuring the protection of eco-centric based cultural and heritage rights involves recognizing and safeguarding the cultural practices, knowledge systems, traditions, and spiritual beliefs of indigenous and local small-scale or traditional fishing communities and other groups that have a close relationship with their surrounding ecosystems. These rights encompass the right to maintain and protect cultural landscapes, sacred sites, traditional	• A representative from TGS should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist with adjusting the relationship between TGS and the traditional communities. Given the socio-political environment, opposition to the project and associated non-technical risks, further meaningful engagement with the leadership and communities are critical from a social perspective. The above mitigation measures demonstrate that there is an onus on the applicant to further engage and develop a deeper understanding of the cultural and social aspects and practices within these communities. The nuances associated with potential disruption of fish behaviour, altered migration patterns, and changes to the ecological dynamics that are crucial to the cultural and heritage aspects tied to fishing, was assessed in detail in the Marine Ecological Assessment and included in Section 9 of the BAR for each of the organism groups. The impacts associated with each of these groups were found to be of LOW significance and fully reversable. It should further be noted that in terms of the fishing, the fisheries assessment was duly cognisant of the relationship between the small scale fishers and the application area, as well as the TEK, which some of the community member referred to during the public meetings, and was duly considered by the specialists. This is evidenced by the following extract from Section 8.5.3.10 of the BAR: *"Small-scale fishermen along the Northern Cape and Western Cape coastlines are*

ecological knowledge, and sustainable resource management practices.[178] 165. The examples of proposed mitigation measures formulated by the EMPr inadequately acknowledge the substantial impact on ecosystem/ecocentric based cultural and heritage rights resulting from the broader indirect and cumulative consequences on fishing populations. 165.1. Implementing exclusion zones to minimize direct impacts on fish populations and sensitive habitats does not sufficiently address the broader ecosystem/ecosystem based cultural and heritage associations of fishing. While exclusion zones can help protect specific areas from immediate harm, they may not consider the holistic connections between fish populations, migration routes, and the cultural practices of coastal communities that extend beyond specific locations. 165.2. Using sound mitigation technologies, such as acoustic deterrent devices, can help reduce the direct impacts of seismic surveys on marine life. However, these measures may not fully address the indirect and cumulative effects on cultural and heritage rights. They primarily focus on	*unlikely to range beyond 20 km from the coastline; thus, inshore of the Reconnaissance Permit area (refer to Figure 83). This assessment is however cognisant of the ongoing issues related to the perceived areas fished and species targeted by SSF off the West Coast of South Africa e.g. that cultural practice of SSF may occur to 55 km offshore. While SSF regulations clearly specify that fishing is required to take place "nearshore" the actual differentiation between SSF and other fishing operations that might include SSF, such as the commercial "traditional linefish" and "pole and line" and the extent to which these commercial fisheries might include SSF, remains unclear. As such the offshore extent to which SSF may operate requires a precautionary approach in this assessment and consideration that the possibility exists (albeit a remote possibility that cannot be verified through the information made available on these fisheries), that SSF may have occurred historically and potentially in the future further offshore than suggested by the information made available for this assessment i.e. there is a remote possibility that some SSF may have targeted certain species (of which tuna and snoek are the main candidate species) further offshore than 20 km. The distance fished offshore by SSF and the associated risks determined in this assessment further necessarily considers practical aspects, notably that bottom fishing is impractical in waters deeper than 100 m and as such any bottom fishing, whether SSF or commercial, is highly unlikely beyond a precautionary depth being the 100 m depth contour. Further, in regard to migratory species, such as longfin tuna and snoek, economic and regulatory aspects relating to distances fished offshore is pertinent (i.e. such as the requirements of the South African Maritime Safety Authority (SAMSA)) in particular that most SSF are not likely to be "B" class certified (i.e. can operate up to 40 nm offshore and*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
reducing noise levels and immediate physical harm, but do not consider the potential disruption of fish behavior, altered migration patterns, or changes to the ecological dynamics that are crucial to the cultural and heritage aspects tied to fishing. 165.3. Temporal restrictions, such as conducting seismic surveys during specific seasons or avoiding critical reproductive periods, may help reduce direct impacts on fish populations. However, these restrictions may not fully address the indirect and cumulative effects on the cultural and heritage rights associated with fishing. Cultural practices and traditional knowledge often extend beyond specific seasons and reproductive periods, and the long-term sustainability of fishing traditions and associated rights may depend on the availability of fish populations throughout the year. 165.4. Implementing measures specifically focused on protecting certain fish species or habitats may not comprehensively address the broader cultural and heritage rights tied to fishing. While protecting specific species or habitats is important for biodiversity conservation, cultural and heritage associations with fishing often encompass a diverse range of species, ecosystems, and traditional practices that go beyond the conservation of individual components.	*are longer than 9 m) are likely limited to "C" class being mainly vessels of <9 m21 permitted to only operate < 15 nm offshore."* It should be noted that the ecosystem level impact and interrelationships are described in section 4.3.8 of the Marine Ecological Assessment. The recommendation of the SIA is that, should the project be approved a representative from TGS must consult with leadership of the community to determine how the communities should be consulted with in future – that is, what is the way the community members prefer to be consulted with for provision of commencement notification and/or daily updates to advise on survey schedules, communication in respect of the proposed research outcomes, etc. The recommendation to include further consultation as part of the conditions of authorisation intends to ensure that the consultation process goes further than just the EIA process, but is continued throughout the entire process, regardless of the outcome. This will assist communities and people on the ground to make informed decisions about technical matters. The intention of the recommendation is not for this condition to be suspensive or determinant on the ultimate decision but rather to function as an additional management/ mitigation measure to be implemented post approval to reduce the significance of the identified impacts and further enhance the community engagements during implementation, should the project be implemented. The SIA specialist has made a reasoned opinion that the project can be approved on the basis of the outcomes of the consultations already undertaken. Communities are diverse and there are community members who are supportive of this type of development, as much as there are community members against the development. Communities were asked to suggest mitigation measures that the specialists should consider, and this influenced some of the recommendations made in

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
166. To effectively address the indirect and cumulative effects on ecosystem/ecocentric based cultural and heritage rights associated with fishing, mitigation measures should take a more holistic and inclusive approach that consider and incorporate the following aspects: 166.1. Incorporating the perspectives and insights of coastal communities into decision-making processes, ensuring their meaningful participation in the development and implementation of mitigation measures. 166.2. Recognizing and preserving cultural and heritage practices by considering the broader socio-cultural contexts, intergenerational knowledge transfer, and the long-term sustainability of traditional fishing practices. 166.3. Integrating traditional ecological knowledge with scientific research to inform mitigation strategies and ensure that they address the interconnectedness of fish populations, ecosystems, and cultural and heritage rights. 167. While the mitigation measures may focus on reducing direct impacts, there can be indirect and cumulative effects that are not fully addressed. Seismic surveys, even with mitigation, can still cause disturbances, alter fish behavior, or disrupt migration patterns, which may have cascading effects on the broader ecosystem. 168. Given the ecosystem impacts, seismic testing will likely result in a trophic cascade affecting all levels of the food chain and therefore indirectly impacting on small-scale fishing communities. The Fisheries Specialist failed to assess the potential impact of the seismic surveys on zooplankton in and around the survey area, as well as the knock-on effects that zooplankton die-off would have on the fish species on	the SIA. All perspectives were considered during the EIA process and the social impact analysis.	

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
which small-scale and subsistence fishers rely for their sustenance and livelihood.[179] These indirect knock on and cascading effects on the dynamic and interconnected ecosystem could potentially affect not only food security for local small-scale fishing communities, but could also impact on the ecosystem/ecocentric based cultural and heritage rights associated with fishing. Counter to the requirements of NEMA and the NEM:ICMA, the BAR and the competent authority's decision does not consider impacts from an ecosystem perspective, and as a consequence, the "downstream" impacts have not been adequately assessed and presented to the DG. 169. Additionally, the cumulative impacts of multiple surveys or other anthropogenic activities in the area need to be weighed together. These indirect and cumulative impacts can have implications for cultural and heritage associations, as they may disrupt traditional practices and the functioning balance of the marine ecosystem. 170. Given the absence of a socio-economic impact assessment which adopts an ecocentric and ecosystem approach to the assessment of impacts, and which should have evaluated the cascading impacts on food webs, and how this will impact on the right to access of sufficient food as well as the associated connections of heritage and cultural rights to the practices of fishing, relevant information was not placed before the decision-maker. In the absence of that information, a precautionary approach should have been adopted. This omission is material – the right to food and culture and heritage are constitutionally enshrined – and consequently the authorisation should not have been granted.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
171. Small-scale fishers often possess traditional ecological knowledge ("TEK"), which includes their understanding of fish behavior, spawning grounds, and the dynamics of the marine environment. This knowledge is often based on observations passed down through generations and is deeply connected to their cultural heritage. Proposing mitigation measures without considering and incorporating TEK may overlook valuable insights and alternative approaches that could better protect both the fish populations and the ecosystem/ecocentric based cultural and heritage rights of coastal fishing communities. 172. Given the above, it is submitted that the proposed and authorised mitigation measures are inadequate. The mitigation measures set out in the EMPr are designed to re-assess impacts post-project.[187] This is flawed for a number of reasons, including: 172.1. The proposed measures are aimed at providing "resources and support for communities to develop and undertake safeguarding measures or plans to enhance the mitigation capacity of their intangible cultural heritage by fostering dialogue, mutual understanding and reconciliation between and within communities" which in no way holds TGS accountable for any impacts caused by the 3D seismic surveys activities. 172.2. The proposed mitigation measures fail to comprehend and mitigate any of the economic or		

[187] Page 30 of the EMPr

Initials:

2015

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
other harms to livelihoods, and cultural and heritage practices and identity. 173. The pre-mitigation significance given to the socio economic and cultural and heritage impacts are rated as Medium, and then Low post mitigation. If mitigation does not actually change the impacts, then it is implausible that the rating can change significantly as well. There is no rational connection between the results of the arbitrary, and somewhat absurd, mitigation measures and any change in significance with regards to the impacts caused by the reconnaissance activities on coastal communities. 174. The Social Impact Assessment (SIA) and Heritage Impact Assessment urges the need for dialogue and engagement with communities prior to the commencement of these activities as the Expert confirms that the oil and gas companies do not have a social license to continue currently.[161] However, there is evidence of any further dialogue with these communities with regards to addressing issues specifically relating to the indirect and cumulative effects on cultural and heritage rights associated with fishing. 175. Therefore, engaging and involving coastal communities in the decision-making process is crucial. Meaningful consultation and participation allow communities to express their concerns, share their knowledge, and contribute to the development of effective mitigation measures. Failure to include the perspectives and needs of these communities can result in measures that do not adequately		

[161] Page 109-110 of the SIA, and page 56, 58 of HIA.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
address their cultural and heritage associations and may lead to further marginalization. 176. Despite the apparent expert knowledge and the level of understanding expressed in the report recommendations regarding the potential effects of the seismic survey proceeding on the communities' identity, sense of place, and spiritual, cultural, and indigenous rights, and that decisions must consider the interests, needs, and values (our emphasis) of all interested and affected parties, including acknowledging all forms of knowledge, including traditional and ordinary knowledge,[182] it is clear that necessary deep conversations with coastal communities were not conducted. Consequently, insufficient information was placed before the decision-maker, and he/she neglected to afford sufficient weight to the indigenous and cultural rights of coastal communities.		
Ground 6: Failure to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008 177. Section 63(1) of NEM:ICMA requires a competent authority to take account of specific factors when deciding whether or not to grant an environmental authorisation under NEMA for "coastal activities". By virtue of this section, the decision maker ought to have appreciated that in deciding whether to grant an environmental authorisation or not, he or she was required to consider additional	Section 4 of the EAR does list the Integrated Coastal Management Act (ICMA) and the Marine Living Resources Act. The decision-making authority was required to consider the principles and obligations of the ICMA in the decision making process. The marine fauna study assesses the potential impacts of the survey on the marine environment. The proposed survey activities to be undertaken by TGS are expected to result in impacts on marine invertebrate fauna in the Orange Basin, ranging from negligible to very low significance. Only in the case of potential impacts to turtles and marine mammals are impacts of low significance expected. If all

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
factors specified in section 63 of NEM:ICMA[183] and whether or not the proposed project "would be contrary to the interests of the whole community". This required an eco-centric consideration of the impacts of the proposed project in an area that must be afforded a particularly high standard of protection given the natural functioning of the dynamic coastal processes. 178. Section 12 and 21 set out the State's obligation in relation to the management of the coastal zone, which must be taken into account in taking a decision in respect of this zone. 179. The Director-General's decision makes no mention of section 63 of NEM:ICMA, and the ESIA contains no evidence that the factors set out in section 63 was considered or assessed. Whilst the BARidentifies that section 63 of NEM:ICMA is applicable, it does not assess each of the factors set out in section 63. 180. Read together, this means that there was no factual investigation as required by section 63 of the NEM:ICMA, including a determination of whether the coastal public property and the coastal protection zone would be impacted, and if so, to what extent the proposed activity is consistent with the goal of establishing or protecting those areas.[184]The management plans that are relevant in these areas, like the Coastal Management Programme for the	environmental guidelines, and appropriate mitigation measures recommended in this report are implemented, there is no reason why the proposed seismic survey programme should not proceed. With respect to the management and conservation of protected areas noted in the ICMA and MLRA, this is discussed in Section 8.6 of the BA Report. In terms of protected areas, Child's Bank and Tripp Seamount lie outside of the proposed 3D survey area, and any demersal species associated with these important fishing banks would receive the seismic noise within the far field range, and outside of distances at which physiological injury or avoidance would be expected. Despite the current lack of knowledge of the community structure and endemicity of South African macroinfauna off the edge of the continental shelf, the marine component of the 2018 National Biodiversity Assessment, rated the South Atlantic bathyal and abyssal unconsolidated habitat types that characterise depths beyond 500 m, as being of 'Least concern', with only those communities occurring along the shelf edge (-500 m) being considered 'Vulnerable'. This primarily reflects the great extent of these habitats in the EEZ. Numerous sanctuaries, marine protected area (MPA) exist offshore and along the coastline of the Western Cape, although none of them overlap with the Reconnaissance Permit Area. Seismic surveying is not only used for petroleum and natural gas exploration and development. In addition, the National Coastal and Marine Spatial Biodiversity Plan for the coast and ocean around the South African mainland states that petroleum production may be possible in CBAs using lateral drilling or other techniques that do not result in biodiversity impacts. According	

[183] S 63(1)(c), s 63(1)(h)(i), s 63(1)(h)(iv) and s 63(1)(i) of NEM:ICMA.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Western Cape Province,[185] have also not been taken into consideration. 181 The BAR does not, at any point, consider the interests of the affected human and non-human communities in any collective way. Consequently, the interests of the whole community[186] have not been presented to the decision-maker in the BAR, and without evidence of specific consideration of these interests in the Reasons for the Decision, the decision-maker has not evaluated these interests in their decision to grant environmental authorisation. 182. As set out elsewhere in this appeal, the impacts associated with seismic surveys could have significant impacts on marine life and coastal communities. Oceans play a critical role in regulating the climate and mitigating global warming by absorbing carbon dioxide. Seismic surveys pose a significant threat to functioning marine ecosystems, to living organisms in South Africa's coastal waters, and	to the plan if significant petroleum resources are identified in these areas the selection of the site as a CBA could be re-evaluated, although this would require alternative CBAs to be identified to meet biodiversity targets. No MPAs are located within the proposed survey area. Zero no-go areas within the proposed survey area have been identified in any of the specialist studies conducted. It should further be noted that the interests of the whole community (from and intra- and inter-generational perspective, as well as having regard to potential impacts on living organisms in South Africa's coastal waters) was indeed assessed in the assessing of the marine ecology, the impact on the fishing industry, the detailed social and cultural heritage assessments, and the public consultation undertaken. With regards to the requirements of Section 63 of the NEM:ICMA, the Competent Authority thus had sufficient information at their disposal in order to reach an informed decision regarding the proposed activity.	

[185] Western Cape Coastal Management Programme: 2016 available at https://cer.org.za/wp-content/uploads/2009/12/Western-Cape.pdf
Draft Western Cape Coastal management Programme 2022 – 2027 available at https://www.westerncape.gov.za/eadp/files/atoms/files/DRAFT%20Western%20Cape%20Provincial%20Coastal%20Management%20Programme%202022-2027.pdf.

[186] In terms of the National Environmental Management: Integrated Coastal Management Act 24 of 2008 (NEM:ICMA), the 'interests of the whole community' is defined as meaning the collective interests of the community determined by:

(a) prioritising the collective interests in coastal public property of all persons living in the Republic over the interests of a particular group or sector of society;

(b) adopting a long-term perspective that takes into account the interests of future generations in inheriting coastal public property and a coastal environment characterised by healthy and productive ecosystems and economic activities that are ecologically and socially sustainable; and

taking into account the interests of other living organisms that are dependent on the coastal environment.

Initials:

2019

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
to communities that depend upon the oceans for their livelihoods. Small-scale fishers and fishing-dependent communities are particularly vulnerable to the negative impacts on fish stocks upon which they depend for their livelihoods. 183. The Appellants submit that it is not in the interests of the whole community (from and intra- and inter-generational perspective, as well as having regard to potential impacts on living organisms in South Africa's coastal waters) to expose our oceans and coasts to the increased risks associated with seismic surveys, or associated with further intended exploratory drilling and/or production activities.		
<u>Ground 7</u> *Failure to provide adequate reasons for the decision* 184. The reasons for the DG's decision, as described in Appendix 1 of the Environmental Authorisation ("the EA"), sets out that the following were 'key findings' that resulted in the decision to approve TGS's application for environmental authorisation: 185. The decision concludes as follows: *In view of the above, and having taken into consideration environmental management principles as set out in section 2 of NEMA, this Department is satisfied that the proposed activity will not be in conflict with the objectives of Integrated Environmental Management set out in Chapter 5*	It is the opinion of the Applicant that the Competent Authority thus had sufficient information at their disposal in order to reach an informed decision regarding the proposed activity.	

Initials:

2020

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
of [NEMA] and will not result to any detrimental risks to the environment and public. The environmental authorisation is accordingly granted. 186. These reasons, and the conclusion arising from these reasons are generic and unsubstantiated. The reasons are almost verbatim the same reasons provided by the DG in other oil and gas related applications, such as those contained in the Environmental Authorisations for Searcher Geodata UK Limited and TotalEnergies EP South Africa Block 567 (Pty) Ltd . The EA itself further fails to deal substantively with any of the main issues raised by the Appellants and other I&APs. 187. On the reasons provided, it is impossible to conclude that the DG took all relevant considerations into account, including the submissions made by the Appellants and other interested and affected parties. To the contrary, it appears that the DG failed to consider all relevant information, for the reasons set out elsewhere in this appeal		
Ground 8. Decision to grant authorisation contravenes NEMA Principles, the Constitution and PAIA 190. Section 33 of the Constitution recognises that everyone has the right to administrative action that is lawful, reasonable and procedurally fair. PAIA seeks to give effect to this right.	It is the opinion of the Applicant that the Competent Authority thus had sufficient information at their disposal in order to reach an informed decision regarding the proposed activity.	

Initials

2021

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
191. From what is set out above, it is clear that the decision to grant authorisation to TGS runs contrary to at least the following NEMA principles: 191.1 Decision-makers must apply the precautionary principle when there is uncertainty or lack of scientific consensus regarding potential environmental harm. This principle requires taking preventive action to avoid serious or irreversible environmental damage, even in the absence of full scientific certainty. 191.2. Decision-making should promote equity and fairness in the distribution of environmental benefits and burdens. This principle recognizes the rights of all individuals, particularly disadvantaged and vulnerable groups, to a healthy environment and seeks to avoid disproportionately negative impacts on these groups. 191.3. Decision-makers must protect and conserve ecosystems, biodiversity, and ecological processes. This principle recognizes the intrinsic value of ecosystems and the critical role they play in supporting life and maintaining ecological balance. 192. It is further submitted that 192.1. irrelevant considerations were taken into account or relevant considerations were not considered;		

Initial/s

2022

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
192.2. the action itself contravenes a law or is not authorised by an empowering provision; 192.3. the action itself is not rationally connected to the information before the administrator; and 192.4. the exercise of the power or the performance of the function authorised by the empowering provision, in pursuance of which administrative action was purportedly taken, is so unreasonable that no reasonable person could have so exercised the power or performed the function. 193. The decision is consequently reviewable under section 6(2) of PAJA. CONCLUSION 194. The Appellants have sent out in this appeal a number of grounds on which the decision to grant environmental authorisation to TGS was fatally flawed. The decision to authorise the project is consequently unlawful, in that it failed to comply with, inter alia, the Constitution and NEMA.

REPORT ON SCIENTIFIC BASIS FOR CONCERNS OF SIGNIFICANT HARM INFLICTED TO MARINE WILDLIFE BY 2D and 3D SEISMIC SURVEYS ON THE SOUTH AND WEST COASTS OF SOUTH AFRICA

Harris JM, Olbers JM, Wright K

14 January 2022

This report provides a summary of key findings in peer-reviewed literature on the physiological and ecological impacts of seismic survey activities on marine wildlife, with specific attention to the relevance of the information to the context of the Reconnaissance Permit Area (~297 089 km^2) applied for by Searcher Geodata UK Limited, located offshore between the South African/Namibian border and Cape Agulhas, as well as with regards to vulnerable and endangered species known to occur in this area, with consideration of the proposed timing of the seismic survey operations being during the austral summer months. Having carefully considered the available information it is our opinion that seismic surveys do cause harm to both species and ecosystems, and that significant direct harm to individual animals and harm to populations of endangered species is the most likely scenario in the case of the seismic surveys off the south and west coasts of South Africa. Of specific concern is the impact on humpback whales and southern right whales which are still frequenting the west coast during the summer months (December – February), the impact on critically endangered (leatherback) turtles (migration routes in the area), the critically endangered African Penguin (changes in foraging behaviour and impacts on fitness) and the Cape fur seal (and consideration of current mass die-offs). We conclude that these seismic surveys are inadvisable in austral summer months due to the presence of these species in the area, the increasing anthropogenic

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
INTRODUCTION 1. This is an appeal to the Honourable Minister of Forestry, Fisheries and the Environment ("Appeal" to the "Minister"), directed to the Director: Appeals and Legal Review of the Department of Forestry, Fisheries and the Environment ("DFFE"), to set aside the decision of the Director-General of the Department of Mineral Resources and Energy (as "DG" or "DMRE") dated 17 April 2023 granting environmental authorisation to TGS Geophysical Company (UK) (as "Third Respondent") allowing for a 3D seismic survey off the West Coast of South Africa. 2. The Minister should set aside the decision to grant authorization because the Environmental Basic Assessment Report (FBAR) did not comply with NEMA in several ways. The decision to grant authorization violates various provisions of NEMA, including the requirements for granting environmental authorizations and the National Environmental Management Principles. The FBAR and the decision-maker failed to establish the need and desirability of the Project, failed to adequately consider marine impacts, and neglected to assess the cumulative impacts of the Project. The Second and Third Respondent also failed to engage in meaningful consultation, violating principles of fair administrative decision-making and the right of affected communities to be consulted. This failure to consult is inconsistent with NEMA's requirement to promote participation and take into account the interests of all parties. Moreover, the decision-maker disregarded NEMA Principles, including the precautionary principle and the principle of sustainable development, as well as the constitutional right to a non-harmful environment. The decision therefore to issue the authorization and the reasons provided are deemed irrational and unreasonable. 3. The Appellant submit this appeal on the following grounds:	For the reasons provided in the responses below it is the opinion of TGS Geophysical Company (UK) (TGS) that the Environmental Authorisation (EA) should remain valid, since the Basic Assessment Process was conducted in line with the requirements of the Environmental Impact Assessment (EIA) Regulations, 2014, as amended. This included amongst others that: • The Need and Desirability of the Project was adequately addressed and assessed – Refer to Section 5 of the Basic Assessment Report (BAR)); • Marine and cumulative impacts were considered in detail in the BAR – refer to Section 9 of the BAR; • The EAP appointed for the project conducted an extensive Public Consultation Process, which resulted in meaningful consultation – Refer to Section 7 and Appendix 2 of the BAR; • As stated in Section 11.3 of the BAR, The findings of the specialist studies conclude that there are no environmental fatal flaws that should prevent the proposed project from proceeding, provided that the recommended mitigation and management measures are implemented. Based on the nature and extent of the proposed project, the local level of disturbance predicted as a result of the reconnaissance activities, the findings of the specialist studies, and the understanding of the significance level of potential environmental impacts, it is the opinion of the EIA project team and the EAP that the significance levels of the majority of identified negative impacts can generally be reduced to an acceptable level by implementing the recommended mitigation measures and the project should be authorized.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
6. In accordance with the requirements of Regulation 4(2)(a) of the Appeal Regulations: 6.1. this Appeal is submitted in writing in the form obtained from the Appeal Administrator, and accompanied by this more detailed appeal document, being a statement setting out the grounds of appeal ("the Grounds of Appeal"). The Appellants are entitled to also submit these more detailed Grounds of Appeal as the Appeal submission. This submission must be taken into account by the Minister in making a decision on the Appeal; 6.2. to the extent possible, the Appeal is accompanied by relevant supporting documentation which is referred to in this Appeal submission - attached as Annexure B; and 6.3. we confirm, in compliance with Regulation 4(1) of the Appeal Regulations, that this Appeal is submitted within 20 days[1] from the date of notification to I&APs to the Appeal Administrator. A copy of the Appeal will be provided to the Applicant and to those registered I&APs, and organs of state with an interest in the matter, insofar as possible and within time and cost constraints. The statement regarding compliance with Regulation 4(1) is contained in the cover letter to which these Grounds of Appeal are attached. In any event, we confirm compliance with Regulation 4(1). 7. The Appellants further submit that there are grounds for judicial review under the Promotion of Administrative Justice Act, 2000 ("PAJA") because the Authorisation comprises administrative action that *inter alia*.		

[1] The Appellants submit that the process provided for in the Appeal Regulations, in particular the requirement to submit an appeal in 20 days of the notification, severely prejudices the Appellants and infringes on their rights to a fair process. The Appellants continue to assert that the unreasonably short timeframes and onerous notification requirements of regulation 4(1), among others, render the Appeal Regulations a violation of the rights to just administrative action, and are thus unconstitutional.

seismic survey is a large under-explored area with potential for both oil and gas. 13. On the 25th of November 2022, the Applicants submitted comments on the draft Basic Assessment Report prepared as part of the Environmental Impact Assessment (EIA) process. As mentioned above, the DG granted the Project an Environmental Authorisation on 17 April 2023, and the Appellants received notification of the decision on 26 April 2022. 14. The Reasons for the Decision are set out in Annexure 1 to the Authorisation. GROUNDS OF APPEAL 15. The decision to grant the Authorisation should be set aside by the Minister because the final Environmental Basic Assessment Report ("FBAR") failed to comply with NEMA in various respects; and the Director General's decision to grant the Authorisation contravenes various provisions of NEMA, including the requirements for granting environmental authorisations, the requirements of the National Environmental Management Act and the National Environmental Management Principles (section 2 of NEMA) ("NEMA Principles"), in that: 15.1. the need and desirability of the Project has not been established, as required by regulation 18 of the EIA Regulations read with regulation 23(3) and Appendix 3 to the EIA Regulations. 15.2. the FBAR and the DG failed to adequately consider the marine impacts and therefore have failed to meet the requirements of, inter alia, section 240(1) NEMA to account for all relevant factors,[20] in particular those regarding the pollution,		

[20] NEMA, section 2401(b).

Initial/Sign

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
environmental impacts or environmental degradation *"likely to be caused if the application is approved"*,[11] as well as any guidelines, departmental policies, and environmental management instruments and any other information in the possession of the competent authority relevant to the Application.[12] This is also in contravention of the NEMA requirement to ensure that the activity's potential environmental impacts are properly assessed;[13] 15.3. The FBAR and DG have failed to adequately assess and consider the cumulative impacts of the Project, as required by the NEMA EIA Regulations, Appendix 3 section 3(j)(ii). 15.4. TGS, and its appointed Environmental Assessment Practitioner ("EAP", has failed to engage in meaningful consultation in violation of the principles of fair administrative decision-making and the right of interested and affected communities to be meaningfully consulted prior to a decision on authorisation being made, and in violation of section 2(4)(f) of NEMA, which stipulates that the participation of all interested and affected parties in environmental governance must be promoted, and all people must have the opportunity to develop the understanding, skills and capacity necessary for achieving equitable and effective participation, and participation by vulnerable and disadvantaged persons must be ensured. It is also inconsistent with section 2(4)(g) of NEMA, which requires that decisions must take into account the interests, needs and values of all interested and affected parties, and this includes		

[11] NEMA, section 24O1(b)(i).
[12] NEMA, section 24O1(b)(viii).

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
recognising all forms of knowledge, including traditional and ordinary knowledge. 15.5. the DG failed to consider and/or give effect to: the NEMA Principles, including the precautionary principle and the principle that requires development to be environmentally, socially and economically sustainable; and the Constitutional rights to an environment that is not harmful to health or wellbeing – as enshrined in section 24 of the Constitution of the Republic of South Africa, 1996 ("the Constitution"). The decision to issue the Authorisation and the reasons provided therefore are, furthermore irrational and unreasonable, and thus in contravention of PAJA. 15.6. The DG failed to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008. 15.7. Ground 7: The DG failed to provide adequate reasons for the decision.		
Ground 1: A flawed and misguided need and desirability assessment 16 The NEMA EIA Regulations stipulate that a basic assessment report must include a motivation for the need and desirability for the proposed development, including the need and desirability of the activity in the context of the preferred location.[14] 17. Section 5 of the FBAR includes a motivation of need and desirability for the proposed 3D seismic survey. Unsurprisingly, the FBAR	The EAP has conducted the impact assessment on the basis of the activities proposed by the applicant. Any subsequent authorisation would be restricted to these specifically assessed activities. Should the applicant or other applicants wish to undertake any additional exploration activities which are not addressed in the current Environmental Authorisation (EA) application, there would be a consequent need to apply for the relevant permissions. These would include a formal application for an Exploration or Production Right as	

[14] NEMA EIA Regulations, Appendix 1, section 2(c). With regard to need and desirability, a distinction is drawn between the 'general purpose and requirements' of the proposed activity and 'need and desirability'. The 2017 Guideline on Need and Desirability states as follows (at p10):

Initials:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
focuses on justifying the 'need and desirability' of the proposed project and fails to reflect views critical to 3D seismic surveys and offshore oil and gas exploration (and ultimately production). As a consequence, the 'need and desirability' assessment provided in the FBAR follows the pattern of previous seismic survey EIAs by (among other things) limiting the assessment of potential impacts to the proposed 3D seismic survey, with no assessment of the need and desirability of exploring for (and ultimately producing and using) new oil and gas reserves (including in the context of the climate change crisis and the right to food). The assessment also includes a section motivating the 'need' for seismic data. 18. It is noted that the FBAR Needs and Desirability analysis indicates that the proposed project '*aims to identify oil and gas resources to be used in... energy production and/or processing or manufacturing of materials*'.[15] The FBAR also claims in passing that "seismic surveying is not only used for petroleum and natural gas exploration and development, it can in certain instances also be used for	well as a new EA. The impacts of such proposed activities would consequently require specific assessment and public consultation prior to approval. It is premature to assess the likely impacts of further invasive exploration activities or production activities as the extent, duration, location, and magnitude applicable to these activities are unknown at this stage. The NEMA EIA Regulations make a clear distinction between the reconnaissance, exploration, and production activities in that these are listed as distinct and separate listed activities. There is provision in law for these activities to be assessed on their merits as and when they are proposed. Please refer to Section 5 of the BA Report in regard to the need and desirability for the proposed activities. According to the Integrated Resource Plan 2019 (IRP 2019), which is the country's electricity planning strategy, there is a need for gas in South Africa's energy mix in the future. This need is driven in part by the expectation that natural gas may act as a transition fuel, whilst other greener technologies mature. According to the National Department of Forestry, Fisheries	

In order to properly interpret the EIA Regulations' requirement to consider "need and desirability", it is necessary to turn to the principles contained in NEMA, which serve as a guide for the interpretation, administration and implementation of NEMA and the EIA Regulations. With regard to the issue of "need", it is important to note that this "need" is not the same as the "general purpose and requirements" of the activity. While the "general purpose and requirements" of the activity might to some extent relate to the specific requirements, intentions and reasons that the applicant has for proposing the specific activity, the "need" relates to the interests and needs of the broader public.

...

The consideration of "need and desirability" in EIA decision-making therefore requires the consideration of the strategic context of the development proposal along with the broader societal needs and the public interest. The government decision-makers, together with the environmental assessment practitioners and planners, are therefore accountable to the public and must serve their social, economic and ecological needs equitably. Ultimately development must not exceed ecological limits in order to secure ecological integrity, while the proposed actions of individuals must be measured against the short-term and long-term public interest in order to promote justifiable social and economic development – i.e. ensuring the simultaneous achievement of the triple bottom-line. Considering the merits of a specific application in terms of the need and desirability considerations, it must be decided which alternatives represent the 'most practicable environmental option', which in terms of the definition in NEMA and the purpose of the EIA Regulations are that option that provides the most benefit and causes the least damage to the environment as a whole, at a cost acceptable to society, in the long-term as well as in the short-term. (emphasis added)

The Guideline requires need and desirability assessments to address the impact of planned activities on global and international responsibilities relating to the environment, including climate change (at p11).

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
development of offshore wind, geothermal energy, and low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes." This statement about other uses is misguided and irrelevant. These other purposes of the projects surveying results are speculative at best, and have far less impacts on the ocean than oil and gas surveying.[16] It is also abundantly clear from the FBAR that the main purpose of this project is to survey for oil and gas deposits. 19. The FBAR concludes that *'[a]s a result of the fact that this project entails only survey activities, it is anticipated that this project will not lead to a significant impact on the receiving environment'*.[17] In line with this, the FBAR does not consider or assess the potential climate and other negative impacts of subsequent oil and gas exploration, production and use. In other words, it fails to consider the lifecycle impacts associated with exploring for and exploiting oil and gas resources. Yet, at the same time, it does consider the positive impacts should oil and gas be eventually produced, such as the claim that it will provide energy security to South Africa. This self-serving analysis is not only deceiving, it is unlawful. ***Climate change impacts***	and the Environment (DFFE), targets have been determined to achieve our national GHG emissions commitments. These targets consider the likely GHG emissions outcome of the implementation of current South African policies including the IRP. The proposed seismic activities may be used to determine whether a viable gas or oil resource is present. The outcomes of this could provide insight into potential alternative supply options to inform the future energy planning and policy for South Africa. Considering this, and other new information on supply options, as well as the rapid technological advancements in the energy sector (and specifically in the low carbon alternatives), it is crucial that the energy planning for South Africa is continually reassessed and revised to ensure that the most suitable and sustainable strategy is defined. The 2021 NDC's are aligned with the IRP 2019. The GHG emissions and associated climate change impacts associated with the seismic survey itself would be negligible. There are no significant GHG emissions directly related to the proposed activity nor significant climate change vulnerability risks. As such, the life-cycle of the project would be limited to the Reconnaissance activities only (i.e. identification only – and does not necessarily imply actual exploration or further production of oil and gas resources) and	

[16] For example, the offshore wind industry does not use airguns, and instead relies on High Resolution Geophysical (HRG) surveys to map the ocean bottom and its shallow geological features. That technology, such as echosounders, sidescan sonar, and sparkers, uses considerably less power as compared to seismic airguns and also tends to operate at higher frequencies. Not only do higher frequency sounds dissipate more quickly in the ocean but they also tend to fall outside of the general hearing range of baleen whales, such as humpbacks and right whales. The use of seismic surveying to develop offshore wind is the equivalent of using a hammer when a feather could do the job. The area that is being surveyed is also 120 – 230 km offshore and includes deep to ultradeep depths between 1,500 – 4,000m. It would not be feasible to install a fixed nor floating turbines at those depths, as they are more suitable for depths of less than 50m and 50 to 1,000m, respectively Lastly, a World Bank analysis does not find the area TGS is surveying to be ideal for offshore wind generation. ESMAP. 2019. Going Global: Expanding Offshore Wind to Emerging Markets at p. 20-21. Washington, DC: World Bank ("fixed foundation is considered technically viable in areas with water depth less than 50 m and average wind speeds over 7 m/s. Floating wind is considered technically viable with water depths from 50 m up to 1,000 m.").

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
20. The FBAR states that from a climate change perspective, it is '*not currently possible to accurately assess the risks associated with oil and gas activities, given that the specific details of these potential future activities are not known and therefore climate change impacts would need to be assessed in detail during any subsequent Scoping and EIA processes for any potential subsequent oil and gas production projects*'.[18] As a result, the FBAR does not conduct any climate change impact assessment, even in broad terms. 21. It is relevant to note that the issue of whether the decision-maker properly considered climate change impacts was referred to in the judgment of the full bench of the Makhanda High Court in the Shell Wild Coast seismic survey case.[19] The court stated in its judgement that the intervening parties' contention that the decision-maker gave no proper consideration to climate change impacts of the decision to grant the exploration right is an important factor to be considered in the process of granting an exploration right. The court referred to expert testimony relied upon to support this contention, which showed that '*most of the discovered reserves of oil and gas cannot be burnt if we are to stay on the pathway to keep global average temperature increases below 1.5 degrees Celsius. Authorising new oil and gas exploration, with its goal of finding exploitable oil and/or gas reserves and consequently leading to production, is not consistent with South Africa complying with its international climate change commitments*'.[20] 22 The court noted that according to the respondents in that case, climate change considerations are irrelevant when considering an	this has been specified and defined in the Need and Desirability, and the associated impacts identified and assessed. The statement made by the Appellent that the Need and Desirability is misleading and unlawful in that it considers "*positive impacts should oil and gas be eventually produced, such as the claim that it will provide energy security to South Africa*" is in itself misleading and inaccurate. In fact, the Need and Desirability clearly states that "*The proposed project aims to identify oil and gas resources and will not, at this stage, involve the use of the natural resources identified as part of the proposed survey project*" and furthermore makes no claims of any significant positive impacts and states on numerous occasions that "*The proposed activities are anticipated to have low negative ecological impacts. Refer to the impact assessment in Section 9 in this report.*" Also noted is that TGS is a seismic data acquisition company and is in the business of data acquisition, and are not an Oil & Gas Exploration or Production company. Data from TGS' seismic libraries are not only used for petroleum and natural gas exploration and development, data may also be used for development of offshore wind, geothermal energy, low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
application for an exploration right, and these considerations are premature because they fall to be considered at a much later stage. 23. The court pointed out that on the authority of the *Save the Vaal* case,[21] the '*processes are discrete stages in a single process that culminates in the production and combustion of oil and gas, and the emission of greenhouse gases that will exacerbate the climate crisis and impact communities' livelihoods and access to food*'.[22] The court went on to state that the respondent's thesis does not find support in *Earthlife Africa Johannesburg v Minister of Environmental Affairs and Others* either, and referred approvingly to the following passage in Murphy J's judgement: The absence of express provision in the statute requiring a climate change impact assessment does not entail that there is no legal duty to consider climate change as a relevant consideration and does not answer the interpretative question of whether such a duty exists in administrative law. Allowing for the respondents' argument that no empowering vision in NEMA or the regulations explicitly prescribes a mandatory procedure or condition to conduct a formal climate change assessment, the climate change impacts are undoubtedly a relevant consideration as contemplated by section 240 of NEMA for the reasons already discussed. A formal expert report on climate change impacts will be the best evidentiary means of establishing that this relevant factor in its multifaceted dimensions was indeed considered, while the absence of one will be symptomatic of the fact that it was not.[23] 24. The court in the Shell Wild Coast seismic survey case went on to state the following:	The Earthlife Africa case referred to relates to the EA issued to construct and operate a new coal fired power station which bears no resemblance to seismic survey data acquisition. It is agreed that pending the outcome of an appraisal on the viability of extracting any oil or gas resource, which this seismic survey is likely to inform, due caution will need to be taken to avoid overcommitments and stranded assets. In terms of the "Need for Seismic Data", the main aim of the Needs and Desirability Section of the BA Report is to determine the need for the activity, and it is argued for that the survey is desirable given the current energy planning of the country, amongst other factors. It is agreed, considering the rapid technological advancements in the energy sector, that there is a need to continually reassess and revise where relevant the energy planning and policy for South Africa. Pending the outcome of an appraisal on the viability of extracting any oil or gas resource, which this seismic survey is likely to inform, due caution will need to be taken to avoid overcommitments and stranded assets associated with the timing of South Africa's prevailing climate change commitments. The potential for methane leaks during resource extraction, processing, and utilisation will need to be assessed as and when such is proposed. It should further be noted that the acquisition of seismic survey data is considered important with respect to understanding the potential for future oil and gas production as part of the energy mix of the country

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
It seems clear from the aforegoing, even taking into account the contentions raised by the respondents, that, had the decision-maker had the benefit of considering a comprehensive assessment of the need and desirability of exploring for new oil and gas reserves for climate change and the right to food perspective, the decision-maker may well have concluded that the exploration is neither needed nor desirable.[24] (emphasis added) 25. The Green Connection and Natural Justice submit that the FBAR is deficient, and the Needs and Desirability analysis incomplete, without at the very least a broad assessment of the climate change impacts should commercially exploitable oil and gas resources be identified through the proposed seismic survey (and should these resources be produced and utilised). It would be pointless to authorise this (and other) 3D seismic surveys should such an assessment conclude that the development of new oil and gas fields is incompatible with South Africa's climate change commitments. ***The 'climate crisis'*** 26 The need and desirability (from a climate change perspective) of conducting a 3D seismic survey (which – as mentioned above – the FBAR aims to identify oil and gas resources to be used in energy production and/or processing or manufacturing of materials) is particularly important given that climate change has been acknowledged as a 'crisis' with human-induced climate change impacts being experienced in every region. It is also recognised that the climate change 'crisis' requires immediate, rapid and large-scale reductions in greenhouse gas (GHG) emissions to limit global warming to 1.5°C (including accelerated action in this decade to reduce global carbon dioxide emissions by 45 per cent by 2030 relative to the 2010 level and to net-zero around mid-century). In	going forward. The seismic data will provide information with which future decisions can be made. The South African legislation requires the payment of royalties and taxes to the South African government associated with the extraction of resources. There are further obligations on holders of mineral and petroleum rights to contribute to local economic development. The Draft Upstream Petroleum Resources Development Bill also provides for the state to receive a 20% carried interest in exploration and production rights. According to the specialist investigations undertaken, there is unlikely to be a significant impact on the marine environment and therefore there is not anticipated to be a consequent impact on the right to food. It should further be noted that, in the recent Presidential Climate Commission (PCC) recommendations on the electricity system which also specifically considered many local and international studies (including some of those cited by the appellant), the PCC expects a policy adjusted IRP to promote approximately 50 to 60 GW of variable renewable energy by 2050, supported by co-located storage, and between 3 and 5 GW of peaking support (for example gas, running at low utilisations). Therefore, although the PCC doesn't advocate for large scale new coal or gas the PCC does recommend the inclusion of up to 5GW of peaking support (typically to be provided in part by gas). In summary, the re-evaluation of South Africa's energy planning and policy falls beyond the scope of this assessment. The current policy provides for a portion of the electricity mix to be provided by gas, and that such has been accounted for and included in the countries climate change commitments (NDC's). The source of the gas to meet this need would either be imported of produced locally. The feasibility of the later can only be defined once the extent if the resources have been defined.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRS/PASA
support of these submissions, some of the recent developments relating to the climate crisis are discussed briefly below. 27. In August 2021, the Intergovernmental Panel on Climate Change (IPCC) (an international body for assessing the science related to climate change) released its 6th Assessment Report (AR6).[25] In its summary for policymakers, the IPCC indicates (among other things) that: 27.1. it is unequivocal that human influence has warmed the atmosphere, ocean and land, and that widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred;[26] 27.2. the scale of recent changes across the climate system as a whole – and the present state of many aspects of the climate system – are unprecedented over many centuries to many thousands of years;[27] 27.3. human-induced climate change is already affecting many weather and climate extremes in every region across the globe. Evidence of observed changes in extremes such as heatwaves, heavy precipitation, droughts, and tropical cyclones, and, in particular, their attribution to human influence, has strengthened since AR5;[28] 27.4. global surface temperature will continue to increase until at least mid-century under all emissions scenarios considered, and that global warming of 1.5°C and 2°C will be exceeded during	Thereafter a decision can be taken as to whether the resource should be extracted or produced. This EA was issued for seismic survey only and does not result in any stranded assets, but aims to provide information on potential resources. Assessment and analysis of the data acquired by this survey will help inform the Government's decisions on the viability and impact of producing any located assets compared to importing equivalent energy resources.

the 21st century unless deep reductions in CO_2 and other GHG emissions occur in the coming decades;[29] 27.5. Many changes in the climate system become larger in direct relation to increasing global warming. They include increases in the frequency and intensity of hot extremes, marine heatwaves, heavy precipitation, and, in some regions, agricultural and ecological droughts; an increase in the proportion of intense tropical cyclones; and reductions in Arctic sea ice, snow cover and permafrost;[30] 27.6. Continued global warming is projected to further intensify the global water cycle, including its variability, global monsoon precipitation and the severity of wet and dry events;[31] 27.7. Many changes due to past and future GHG emissions are irreversible for centuries to millennia, especially changes in the ocean, ice sheets and global sea level;[32] 27.8. From a physical science perspective, limiting human-induced global warming to a specific level requires limiting cumulative CO_2 emissions, reaching at least net zero CO_2 emissions, along with strong reductions in other GHG emissions. Strong, rapid and sustained reductions in CH_4 emissions would also limit the warming effect resulting from declining aerosol pollution and would improve air quality.[33] 28. On 9 August 2021, the IPCC issued a press release relating to its AR6 report. It states that the report provides new estimates of the

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
chances of crossing the global warming level of 1.5°C in the next decades, and finds that unless there are immediate, rapid and large-scale reductions in GHG emissions, limiting warming to close to 1.5°C or even 2°C will be beyond reach.[34] 29. Also on 9 August 2021, UN Secretary-General António Guterres described the AR6 report as nothing less than "*a code red for humanity. The alarm bells are deafening, and the evidence is irrefutable*". (emphasis added) 30. Guterres is reported as noting that the internationally agreed threshold of 1.5 degrees above pre-industrial levels of global heating was perilously close, and that we are at imminent risk of hitting this threshold in the near term. Guterres is indicated as advising that the only way to prevent exceeding this threshold, is by urgently stepping up our efforts, and pursuing the most ambitious path. Guterres is reported as stating that solutions are clear: "*inclusive and green economies, prosperity, cleaner air and better health are possible for all, if we respond to this crisis with solidarity and courage*". Ahead of the COP26 climate conference in Glasgow in November 2021, Guterres stated that all nations needed to join the net zero emissions coalition, and reinforce their promises on slowing down and reversing global heating "*with credible, concrete, and enhanced Nationally Determined Contributions (NDCs)*" that lay out detailed steps. 31. In April 2022, Guterres tweeted that *'[c]limate activists are sometimes depicted as dangerous radicals. But the truly dangerous radicals are the countries that are increasing the production of fossil fuels. Investing in new fossil fuels infrastructure is moral and economic madness'.*[35] Addressing graduate students in May 2022, Guterres expressed the view that investing in fossil fuels is now "*a*

dead end - economically and environmentally. No amount of greenwashing or spin can change that. So, we must put them on notice: Accountability is coming for those who liquidate our future."[36] 32. The 26th Conference of the Parties of the UNFCCC (COP26) was held in Glasgow in the last quarter of 2021. Recognition of the climate 'crisis', as well as the urgent need to increase effort and to accelerate action to address climate change (including by developing nations), are reflected in the outcome of COP26 and recorded in the Glasgow Climate Pact. The Glasgow Climate Pact (among other things): 32.1. Expresses alarm and utmost concern that human activities have caused around 1.1°C of global warming to date and that impacts are already being felt in every region; 32.2. Reaffirms the long-term global goal to hold the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change; 32.3. Recognizes that the impacts of climate change will be much lower at the temperature increase of 1.5°C compared with 2°C and resolves to pursue efforts to limit the temperature increase to 1.5°C; 32.4. Recognizes that limiting global warming to 1.5°C requires rapid, deep and sustained reductions in global GHG emissions, including reducing global carbon dioxide emissions by 45 per cent by 2030 relative to the 2010 level and to net zero around mid-century as well as deep reductions in other GHGs;

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
32.5. Also recognizes that this requires accelerated action in this critical decade, on the basis of the best available scientific knowledge and equity, reflecting common but differentiated responsibilities and respective capabilities and in the context of sustainable development and efforts to eradicate poverty; 32.6. Invites Parties to consider further actions to reduce by 2030 non-carbon dioxide GHG emissions, including methane which has been identified as a driver of climate change and the main polluting emission from natural gas; 32.7. Calls upon Parties to accelerate the development, deployment and dissemination of technologies, and the adoption of policies, to transition towards low-emission energy systems, including by rapidly scaling up the deployment of clean power generation and energy efficiency measures, including accelerating efforts towards the phasedown of unabated coal power and phase-out of inefficient fossil fuel subsidies, while providing targeted support to the poorest and most vulnerable in line with national circumstances and recognizing the need for support towards a just transition; 32.8. Emphasizes the importance of protecting, conserving and restoring nature and ecosystems, including forests and other terrestrial and marine ecosystems, to achieve the long-term global goal of the Convention by acting as sinks and reservoirs of GHGs and protecting biodiversity, while ensuring social and environmental safeguards. 33. The climate 'crisis' is also recognised by the International Energy Agency (IEA), of which South Africa is an IEA associated country. During or about July 2021, the IEA published its *Net Zero by 2050 – A Roadmap for the Global Energy Sector* report. In the foreword to this report, the Executive Director of the IEA states (among other things) as follows:		

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE OMRE/PASA
We are approaching a decisive moment for international efforts to tackle the climate crisis – a great challenge of our times. The number of countries that have pledged to reach net-zero emissions by mid-century or soon after continues to grow, but so do global greenhouse gas emissions. This gap between rhetoric and action needs to close if we are to have a fighting chance of reaching net zero by 2050 and limiting the rise in global temperatures to 1.5 °C. Doing so requires nothing short of a total transformation of the energy systems that underpin our economies. Despite the current gap between rhetoric and reality on emissions, our Roadmap shows that there are still pathways to reach net zero by 2050. The one on which we focus is – in our analysis – the most technically feasible, cost-effective and socially acceptable. Even so, that pathway remains narrow and extremely challenging, requiring all stakeholders – governments, businesses, investors and citizens – to take action this year and every year after so that the goal does not slip out of reach. This report sets out clear milestones – more than 400 in total, spanning all sectors and technologies – for what needs to happen, and when, to transform the global economy from one dominated by fossil fuels into one powered predominantly by renewable energy like solar and wind. Our pathway requires vast amounts of investment, innovation, skilful policy design and implementation, technology deployment, infrastructure building, international co-operation and efforts across many other areas. Since the IEA's founding in 1974, one of its core missions has been to promote secure and affordable energy supplies to foster economic growth. This has remained a key concern of our Roadmap, drawing on special analysis carried out with the International Monetary Fund and the International Institute for Applied Systems Analysis. It shows that the enormous challenge of transforming our energy system is also a huge opportunity for our economies, with the potential to create millions of new jobs and boost economic growth.		

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Another guiding principle of the Roadmap is that clean energy transitions must be fair and inclusive, leaving nobody behind. We have to ensure that developing economies receive the financing and technological know-how they need to continue building their energy systems to meet the needs of their expanding populations and economies in a sustainable way. It is a moral imperative to bring electricity to the hundreds of millions of people who currently re deprived of access to it, the majority in of them in Africa... 34. On fossil fuels used in energy production, the report states that: ***There is no need for investment in new fossil fuel supply in our net zero pathway.*** Beyond projects already committed as of 2021, there are no new oil and gas fields approved for development in our pathway, and no new coal mines or mine extensions are required. 35. When natural gas is burned for energy, it releases carbon dioxide into the atmosphere. More importantly, the extraction, processing, transport and use of natural gas cause significant amounts of methane to be released into the atmosphere too. *According to the United Nations, methane is a 84-86 times more potent greenhouse gas than carbon dioxide over a 20-year period, and 28-34 times more potent over 100-year period.*[37] More research is also showing that methane often leaks during the production, transport and use of natural gas. Therefore, its contribution to climate change is significantly unaccounted for.[38] Drones, laser absorption spectroscopy, and satellites, among other new methane monitoring technologies, have improved the identification and quantification of emissions across the gas lifecycle, leading researchers to conclude		

[37] International Energy Agency, Global Methane Tracker 2022- Overview, https://www.iea.org/reports/global-methane-tracker-2022/overview. See also International Energy Agency, Global Energy Review: CO2 Emissions in 2021,(2022), https://iea.blob.core.windows.net/assets/c3086240-732b-4f6a-89d7-db01be018f5e/GlobalEnergyReviewCO2EmissionsIn2021.pdf.

[38] South Africa is likely among those that are underreporting because the Technical Guidelines for GHG reporting uses outdated emission factors from the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines

Initials

2048

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
that national governments have almost universally underestimated these emissions.[39] 36. If 3,000 megawatts of new gas-to-power plants were built to meet South Africa's 2019 Integrated Resource Plan for Electricity, and the plants were fuelled by imported LNG, the annual emissions from this fuel use would be more than 2.5 million tonnes of CO2e (carbon dioxide equivalent) if the plants ran at 75% capacity. This is the equivalent of driving over half a million gasoline-powered vehicles for a year.[40] For gas or any other fossil fuel, a life-cycle analysis is therefore necessary to quantify the total amounts of GHG emissions (predominantly carbon dioxide and methane) that result from every step in the energy production process: from extracting the fossil fuel at the well or mine to burning it at a power plant or other facility. This is therefore important because all these processes are linked and should not be viewed in isolation. ***South Africa's international climate change commitments*** 37. South Africa is a Party to the United Nations Framework Convention on Climate Change (UNFCCC), which enjoins State Parties to take precautionary measures to anticipate, prevent or minimize the causes of climate change (Article 3.3). 38. South Africa, as a Party to the UNFCCC that ratified the Kyoto Protocol and adopted the Paris Agreement, has committed to *'working with others to ensure temperature increases are kept well below 2°C above pre-industrial levels, which could include a further revision of the temperature goal to below 1.5°C in light of emerging*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
science' by reducing GHG emissions. South Africa has also committed (among other things) to: 38.1. Preparing, communicating and maintaining Nationally Determined Contributions (NDCs) that it intends to achieve reach global peaking of GHG emissions as soon as possible, and to undertake rapid reductions thereafter;[41] and 38.2. Striving to formulate and communicate long-term GHG emission development strategies.[42] 39. There have been various Conferences of the Parties and meetings since, with decisions related to Nationally Determined Contributions (NDCs) contained in decisions 4/CMA.1 and 18/CMA.1 and their annexes. 40. South Africa submitted its first intended Nationally Determined Contribution under the Paris Agreement on 25 September 2015, which became the country's first NDC on 1 November 2016. Subsequently, South Africa revised its first NDC in 2021:[43]\ [illegible]

[41] Paris Agreement, Article 4.1 – 4.3.

[42] Paris Agreement, Article 4.19

[43] Available online at: https://www.dffe.gov.za/sites/default/files/reports/draftnationallydeterminedcontributions_2021updated.pdf#:~:text=South%20Africa%E2%80%99s%20intended%20nationally%20determined%20contribution%20%28INDC%29%28RSA%2C%20n.d.%29,Agreement.%20The%20INDC%20and%20first%20NDC%20are%20identical. This revised NDC is indicated as an enhancement and update of South Africa's NDC under the Paris Agreement, 'meeting its obligation under Article 4.9 to communicate NDC's every 5 years, and responding to requests in paragraphs 23 to 25 of decision 1/CP.21'. South Africa's second (next) NDC is intended to be communicated in 2025.

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
41. South Africa's energy sector is estimated at contributing about 84% percent to the country's overall GHG emissions (including Carbon Dioxide and Methane).[44] 42. In February 2020, South Africa submitted to the UNFCCC its first long-term low GHG emission development strategy titled *South Africa's Low Emission Development Strategy 2050*. It is indicated in the executive summary of this strategy that South Africa, as one of the top 20 global GHG emitters and with a high dependency on fossil fuels, will need to make substantial emission cuts to contribute its fair share to global GHG emission reductions.[45] 43. The FBAR does not provide any indication (or estimation) of how future GHG emissions (resulting from future exploitation of oil and gas that may be discovered through the exploration drilling project) would impact on South Africa's ability to achieve its GHG emissions targets (as set out in South Africa's NDC) or its updated GHG emissions targets (as set out in South Africa's revised NDC). This is particularly relevant given that the emissions targets for the 2026-2030 period are lower than the targets for the 2021-2025 period, while offshore oil and gas developments could take at least a decade to reach the production stage. This could result in offshore oil and gas investments (as well as associated gas infrastructure developments) in the future becoming unneeded 'stranded assets' and a burden on future generations. There is also a risk that in the future tariffs will be levied on various goods exported by fossil-fuel dependent countries – the European Union is reported to be

gradually phasing in its Border Adjustment Mechanism as part of the EU's Green Deal.[45] *Need for seismic data* 44. Under the sub-heading 'Need for seismic data', the FBAR states that a discussion of the needs and desirability of the project '*would not be complete without understanding the need for acquisition of the seismic data and possible oil and gas exploration and production that could potentially take place in the future as a result of the survey*'.[47] 45. Ironically, the FBAR then quickly goes on to state that '*It cannot be said with absolute certainty that exploration drilling, let alone production activities, will be undertaken in the future. As such, it is not currently possible to accurately assess the risks associated with these activities, given that the specific details of these potential future activities are not known. While it is acknowledged that the risks mentioned would need assessment, such assessment falls outside of the scope of the current application and would need to be assessed in detail during subsequent Scoping and EIA processes, should exploration drilling or production be proposed. The environmental consequences applicable to the planned survey activities have been identified and assessed in this BA Report*'.[48] The views of the Makhanda High Court in this regard (in the context of future production, climate change and the right to food) have been traversed earlier in the Green Connection and Natural Justice's comments (see paragraphs 27 to 30 above) and are not repeated here. The Green Connection and Natural Justice stands by their view that at the very least a broad assessment of the impacts and risks

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
associated with future invasive exploration activities, production activities and use of any discovered oil reserves should be included in the BAR. 46. The FBAR report then proceeds with a glowing (and one-sided) endorsement of the use of natural gas: **The fastest growing sector for the use of natural gas is for the generation of electric power. Natural gas power plants usually generate electricity in gas turbines, directly using the hot exhaust gases from the combustion of the gas.. Of the three fossil fuels used for electric power generation (coal, oil and natural gas), natural gas emits the least carbon dioxide per unit of energy produced. Natural gas emits 30% and 45% less carbon dioxide than burning oil and coal, respectively. Burning natural gas also releases lower amounts of nitrogen oxides, sulphur dioxide, particulates and mercury when compared to coal and oil.** **The increased use of natural gas can, in the short term, serve as a transition fuel on the path to the carbon-neutral goal of the Paris Agreement. In addition to gas as a key transitional fuel reducing reliance on coal, the benefits of oil and gas could include significant amount of job creation, especially if local beneficiation takes place. An increase in domestic natural gas reserves would enable South Africa to take steps to secure the countries' energy supply (through diversification), assist in reducing the emissions of greenhouse gases (by reducing the country's reliance on coal for electricity generation) and reduce the need for the importation of gas. As such, exploration for additional domestic hydrocarbon reserves is considered important and supported by national policy, and any discoveries would be well received by the local market and are consistent with the objectives stated in the 2019 IRP. Natural gas emits 30% and 45% less carbon dioxide than burning oil and coal, respectively, and 65% less carbon dioxide than coal when the increased efficiency of Combined Cycle Gas Turbines versus coal fired power stations is considered. Eskom produces over 200MtCO2/yr, over 40% of South Africa's total. South Africa also has SASOL's Secunda coal to liquids**		

2053

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
plant, the biggest single source of CO2 in the world at 57MtCO2/yr (~12.5% of South Africa's total) to produce 160k barrels of products per day. Supplying these products from conventional oil production and refining would generate approximately 10% of those emissions, 5 to 6MtCO2/yr. According to the 2019 IRP the availability of gas in the short to medium term is a risk as South Africa does not currently have gas resources. There is also a supply and foreign exchange risk associated with likely increase in gas volumes depending on the energy mix adopted post 2030 when a large number of coal fired power stations are decommissioned. South Africa's economic growth is dependent on the availability of energy, ensuring a sustainable and reliable supply of electricity with sufficient capacity is a key aspect to growing the economy of South Africa in the future. The electricity shortages experienced in South Africa over the past decade are a contributing factor to the significant slowdown in economic growth rate. To enable economic growth within the target rate of between 6% and 8% to be achieved, it will be necessary for Government to continue increasing electricity generating capacity in the country. The use of natural gas for electricity generation is identified in national policy, together with renewable energy technologies, as an alternative in diversifying the domestic energy supply away from its current reliance on coal. Gas is identified in the draft Integrated Resources Plan as significant contributor to South Africa's energy mix in the period up to 2050. Availability of gas also provides an opportunity to convert to Combined Cycle Gas Turbine and run open-cycle gas turbine plants at Ankerlig (Saldanha Bay), Gourikwa (Mossel Bay), Avon (Outside Durban) and Dedisa (Coega IDZ) on gas (IRP 2019).[49] 47. Perhaps concerned that it is making the case that seismic surveys are indeed the 'thin edge of the wedge' that will lead to increased fossil fuel extraction, production and use (with associated climate change		

[49] Ibid.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
impacts), the BAR steps back from its natural gas endorsement to repeat the point that *'[f]rom a climate change perspective, it is not currently possible to accurately assess the risks associated with oil and gas activities, given that the specific details of these potential future activities are not known and therefore climate change impacts would need to be assessed in detail during any subsequent Scoping and EIA processes for any potential subsequent oil and gas production projects'.*[50] 48. The FBAR then proceeds to argue that: The feasibility of using natural gas for domestic power generation is considered to be dependent on the extent of available domestic reserves of natural gas, as well as the financial cost of importing natural gas should those reserves be insufficient. The acquisition of seismic survey data is therefore considered important with respect to understanding the potential for future oil and gas production as part of the energy mix of the country going forward and the need and desirability of the project is therefore supported from an energy security perspective.[51] 49. We note here that despite reliance on the IRP to motivate for the project, the FBAR fails to assess whether the amount of gas called for in the IRP would in any event require the exploitation of the resources sought by TGS. 50. Two recent independent studies (among others) challenge the view that fossil gas is necessary for electricity generation and as a transition fuel. 51. The International Institute for Sustainable Development's (IISD) *Gas Pressure: Exploring the case for gas-fired power in South Africa* (March 2022) report points out that while there used to be a rational view that fossil gas would be necessary either during a transition to		

[50] Ibid.
[51] Ibid.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
low-carbon energy or as part of the long-term energy mix for electricity production: "...revolutions first in renewable energy costs and then in battery storage costs have upended this view. Analysis of the South African electricity system shows that gas supply is not technically necessary until at least 2035, if ever. In the last few years, either the risks associated with gas have increased, or the understanding of existing risks has increased. Consequently, South Africa may see significant negative outcomes from developing a large gas-to-power system now... the trend toward decarbonization, coupled with cost reductions for renewable energy and storage, creates risks for gas investment. Investment in gas can reasonably be expected to lead to higher costs for consumers, just transition challenges for workers, and losses for investors."[52] 52. The ISSD report highlights some of the risks associated with gas-to-power investment in South Africa. These risks include significant contributions to climate change (as a consequence of CO_2 and methane emissions when gas is burned), increasing international pressure to move away from gas due to climate impacts, financial risks linked with gas-to-power, the risk of reduced security of affordable gas supply, the risk of stranded assets, and the risk of creating an additional just transition burden (future gas workers and communities face a repeat of the transition hardships currently faced by the coal sector).[53] 53. Meridian Economics' *'Hot Air about Gas – An Economic Analysis of the Scope and Role for Gas-Fired Power Generation in South Africa'* (June 2022) report points out that while South Africa's large-scale use of gas appears to be central to current energy policy direction in South Africa, *'this rests on a 2012 vision which pre-dates dramatic*		

[52] ISSD report, p iv. Available online at: https://www.iisd.org/publications/report/south-africa-no-need-for-gas

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
reductions in renewable energy costs and carbon emissions space'.[54] The report goes on to state that independent analysis of the power sector across multiple recent studies shows that South Africa's power needs can be met both now and in the future with very little use of gas, and that there is *'no evidence to support the large-scale gas envisaged in the GMP; this is uneconomical even before carbon emissions are considered'.*[55] Meridian point out that *'the assumption that gas-fired power generation would replace coal ignores the fact that other technology combinations are now better at replacing coal-fired power than gas, and it is against these technologies that gas-fired generation should actually be compared'.*[56] Meridian demonstrate that existing modelling provides no economic rationale for "big gas" in the power sector, and that *'the impact of using large volumes of gas to generate power will be borne by electricity consumers and will essentially be a subsidy provided by power consumers to otherwise enviable gas use in other sectors'.*[57] 54. The Vital Ambition Report[58] by Meridian Economics in collaboration with the Council for Scientific and Industrial Research ("CSIR") Energy Centre ("Vital Ambition Report") states that gas to power is only justified in the South African energy mix in so far as it is required for low-utilisation flexible capacity (peaker plants) for balancing the system during peak power demand. The report confirms that no investments in gas infrastructure for energy production and generation is needed now or in the near future.[59] Furthermore the

[59] Gas and peaking resources contribute just 1.1% of total electricity generation in 2025, and 2.4% by 2035 according to the same Meridian report.

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
2019 IRP will likely need to be updated in the foreseeable future to align with South Africa's 2021 Nationally Determined Contribution under the Paris Agreement and to keep pace with quickly evolving science and significant reductions in price for solar and wind energy. However, even the 2019 IRP, which is rooted in an outdated and scientifically and economically unsound understanding of the necessity for any gas in the energy mix[60], only projects the collective contribution of gas and diesel to the 2030 energy mix to be 1.3% combined.[61] 55. According to a recent report prepared by Robert W. Howarth titled "Methane emissions and climate warming risk from hydraulic fracturing and shale gas development: implications for policy"[62] the climate impacts of gas are greater than those of coal per unit of energy produced when evaluated over a 20-year timeframe, the period most relevant for climate change if humans are to avoid catastrophic run-away warming. Though gas emits less carbon dioxide per unit energy than coal, its upstream GHG emissions are more problematic for the climate, as it leaks and vents potent methane throughout its lifecycle; researchers have been able to better detect emissions across the lifecycle of gas ever more accurately thanks to new methodologies and technologies (particularly "top-down" measurements using satellite and aerial assessments). 56. The use of fossil fuels must be phased out quickly due to the urgent need to address global warming. A recent study published in *Nature*,

the world's leading multidisciplinary science journal, discovered that "by 2050, we find that nearly 60% of oil and fossil methane gas, and 90% of coal, must remain unextracted to stay within a 1.5 °C carbon budget." According to the study, "most regions must reach peak production now or within the next decade, making many operational and planned fossil fuel projects unviable."[63] It is common practice that proposed exploration activities such as reconnaissance, only commence months and sometimes years after the need and desirability assessment is undertaken, with extraction and production only commencing years later.[64] According to one study, the world's largest oil and gas fields took an average of 5.5 years from discovery to first production and 17 years to reach peak output.[65] Chevron Corporation's (CVX) Gorgon natural gas development project off the coast of Australia took 30 years to complete, and another six years to begin producing liquefied natural gas.[66] Therefore exploration projects whose objectives are to locate gas deposits for energy companies to exploit through the construction and production of fossil fuels, run the risk of creating risks for such infrastructure to become stranded assets which invariably impacts on the development potential of South Africa in achieving its climate goals. With no economic justification for large-scale gas use in power, such a strategy would result in assets that are stranded before their first kWh of power is generated. Given this, the proposed reconnaissance

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
project in no way provides a remedy nor will address in the immediate future South Africa's current energy insecurity issues. 57. Importantly, seismic surveys to explore for oil and gas will not have any immediate impact on South Africa's energy security, as any oil and gas extracted would not belong to South Africa, but would invariably belong to the companies that extract for profit.[57] Energy companies compete for access to mineral rights granted by governments by either entering a concession agreement, meaning any discovered oil and gas are the property of the producers, or form part of a production-sharing agreement which favours the interest of the producers and ultimately diminishing the general interests of the broader South African Republic. 58. The oil and gas that will be eventually extracted by oil and gas companies is ultimately exploited for profit. It is not used to generate a benefit that results in broad based security for energy production nor does it lead to the production of energy for South Africa and its citizens. If oil and gas found following a successful reconnaissance, and that are ultimately exploited, are not used to produce energy for South Africa, this invariably undermines the sole stated goal underpinning the need and desirability of this proposed reconnaissance project—its supposed contribution to energy security for South Africa—and provides no tangible benefit for South Africans. 59. While the increased use of gas as a 'transitional fuel' is promoted by government and vested interest groups, the Green Connection and Natural Justice submit that the increased use of fossil gas (especially in electricity generation) will lead to increased emissions of climate warming GHGs, and methane (CH_4) in particular. While natural gas combustion is less carbon-intensive than that of coal, fugitive emissions arising from the production, transport, storage and use of natural gas have a much greater climate impact than CO_2. In

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
particular, over a 20-year period (which is particularly relevant since the next 20 years are a critical window for addressing the climate crisis) methane emissions, which make up approximately 70-90% of natural gas emissions, are projected to be 82.5 times as impactful as those of CO_2.[68] The desirability of using gas as a 'transitional' fuel is also questionable having regard to volatile international gas prices, as well as the potential risk of Carbon Border Taxes being introduced in the future.[69] This risk will impose restrictions on the export of products with a high carbon footprint, putting South Africa's economy at greater risk of developing gas to power rather than clean renewable alternatives. This invariably diminishes the need and desirability for promoting new gas development projects, as the negative climate impacts and financial risks undermine the potential for gas to represent a viable solution for South Africa's ambitions to address development whilst respecting universal and regional climate change obligations. 60. The fundamental outcome of the need and desirability assessment should not be centred on the determination of whether gas technology will ensure security of supply for electricity. Instead, due to the climate crisis, this assessment should be centred on whether South Africa needs, or should rely on, gas to provide security of supply of electricity and whether alternative technologies could meet the same supply objectives with less harm and risk. Renewable energy and/or storage can replace gas to provide reliable and cost-effective generating capacity while greatly reducing the environmental and health risks associated with gas.[70]

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
61. The call for gas as part of the energy mix set forth in the 2019 IRP does not excuse the decision-maker from taking climate change impacts into account, including as part of the need and desirability assessment. The case for need and desirability must address climate impacts and cannot simply rest on the 2019 IRP as evidence of need or desirability as relied upon by the EAP in the BAR. In the judgment of the High Court in *Earthlife Africa*[71], the court expressed that with respect to a decision maker's reliance on the IRP when rendering a decision on an application for environmental authorisation, the following is important to acknowledge: (a) "Policy instruments developed by the Department of Energy cannot alter the requirements of environmental legislation for relevant climate change factors to be considered".[72] (b) Establishing the need and desirability of a proposed project, is a key objective of each stage of scoping and impact assessment and must account for South Africa's 2021 NDC under the Paris Agreement. The EAP must therefore provide a broad and robust analysis of multiple alternative literature on renewable energy resources and make a justifiable and reasonable case for a project's need and desirability having considered the available literature, without relying solely on the 2019 IRP and other policy documents. This invariably assists the decision maker to prioritise the granting of the best decision which will prioritize the integrity of the environment, and the social welfare, health and safety aspects of the socio-economic environment for present and future generations.		
Ground 2: Failure to adequately consider marine impacts. *Underwater sound from seismic surveys*	The importance of sound is clearly acknowledged in the BAR and consequently a dedicated acoustic modelling assessment was prepared as part of the BAR. EIMS appointed experienced and qualified scientists

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
62. The ocean is an acoustic world. This is because water is a dense medium, and sound travels faster and farther underwater. Marine species, from larvae to whales, utilise this efficiency and have evolved to depend on sound for essential biological functions, including feeding, breeding, communicating, navigating, and socializing.[73] 63. Sound is also a fundamental component of marine habitats. Different ocean environments have distinct acoustic signatures that comprise their acoustic habitat. These acoustic habitats are created from a combination of biological sounds (e.g., fish choruses, snapping shrimp, urchin movement, whale calls) and environmental sounds (e.g. waves crashing, rain, earthquakes). The addition of anthropogenic noise to these soundscapes disrupts the abilities of marine species to use naturally occurring acoustic cues and has detrimental effects on individual organisms, populations, and communities.[74] 64. Seismic airgun blast are the loudest human-created noises introduced into the ocean environment and they travel long distances through seawater. Studies have shown that seismic blasts are at least detectable at distances greater than 500-700 km, even up	to assess the likely impacts from seismic noise. The associated noise impacts were a key focus of the BAR and this clearly indicated in Section 9 of the BAR. It should be noted that a qualified and experienced marine ecology specialist was appointed to conduct an assessment of the likely impacts as identified and described in Section 9.3.1of the BAR. The significance rating for each impact is determined through consideration of the nature, extent, duration, magnitude and probability of each impact. Please refer to section 9.1 of the BAR for an explanation of the assessment methodology utilised. The significance of all identified impacts in the marine ecology report, which included the impacts associated with the underwater sound from the proposed seismic survey, were considered to be of low significance once mitigation has been applied. The significance of environmental impacts varies depending amongst others on the specific location, prevailing sensitivities, receptors, timing, and extent of the proposed activities. The EAP and the specialists identified and assessed potential environmental impacts (supported by inputs from the public consultation process) and has	

[73] Supporting Affidavit of Dr. Aaron N. Rice at paras. 8, *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, attached marked **Annex B1**; Supporting Affidavit of Dr. Douglas P. Nowacek at paras. 9 & 13, *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, attached marked **Annex B2**.

This appeal incorporates the expert opinions of Dr. Rice and Dr. Nowacek who submitted affidavits in the matter of *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021. Both of the affidavits provide expert insight on underwater acoustics, how marine species utilize acoustic cues for biological processes, and how seismic surveys may impact different taxa. The declarations will be used to assist the court to understand general principles and processes and will not be used to support specific impacts that were associated with that case on the east coast of South Africa.

[74] Rice Supporting Affidavit at para. 12.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
to 4,000 km.[75] Other studies have detected seismic surveys at levels sufficient to mask, or obscure, baleen whale calls at distances of thousands of kilometres away from the source.[76] Airgun noise influences and degrades the acoustic habitat of marine species over a far greater area than the metres and kilometres that the EBAR considers and in fact, according to the science, can easily reach coastal areas 120 – 230 km from the survey area. 65. In addition, the noise produced by airgun arrays becomes virtually continuous at greater distances from the source creating chronic noise impacts. This is because the sounds emanating from a seismic airgun array do not behave as individual and finite sound source *in situ* but reflect off the ocean surface and seafloor as they travel, leading to a continuous increase in the sound level through reverberation. The effect has repeatedly been documented.[77] Studies have found seismic surveys causing elevated ambient noise levels by more than 25 dB (approximately a 4-fold increase in noise levels) across distances of 40 km and these sound levels remain elevated during the periods between airgun blasts.[78] Open ocean condition observations have found that the noise produced and were sustained for months at a time.[79] 66. Because of several flaws in its approach, the BAR does not fully identify and assess the risk posed to marine species and ecosystems and does not effectively mitigate the risks from the proposed the proposed surveying.	proposed management and mitigation measures. The impacts are, by virtue of the fact that the impact assessment is a predictive assessment, regarded as 'potential'. All impacts identified in the process can be reduced to a low or medium significance with the implementation of the management and mitigation measures. All impacts associated with a proposed project are considered potential impacts until the impact actually occurs. The studies undertaken internationally over the past ~70 years on the impacts of noise on marine fauna (of which some 400 peer-reviewed publications have been summarised and cited in the marine faunal specialist study) have concluded that the effects of underwater sounds vary substantially and depend on a wide variety of physical and biological factors. When writing articles on the effects of seismic acquisition on marine fauna it is therefore not difficult to bias the literature cited to either demonstrate detrimental and irreversible impacts or only very limited impacts, depending on the personal view of the author(s) and/or the targeted readership. The marine faunal assessment has made efforts to present published results objectively, and nowhere claims that acoustic surveys do not result in impacts. Injury is likely at very short range, with behavioural disturbance occurring over greater distances. The final significance ratings are determined using information from the peer-reviewed literature together with the noise modelling results (which put the threshold distances from the source array to mortality and

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Harms to marine life 67. It is well established that marine seismic surveys cause serious and irreparable harms to marine life. The Biodiversity and Ecosystem Services Assessment Report[24] ("Pisces Report") prepared for the Project acknowledges the a wide range of impacts on numerous species: • Physiological injury and/or mortality; • Behavioural avoidance; • Reduced reproductive success/spawning; • Masking of environmental sounds and communication; • Collision of turtles/marine mammals with the survey and support vessels or entanglement in towed acoustic apparatus; and • Indirect impacts on piscivorous predators due to seismic effects on prey species 68. According to the Pisces Report, the following species are present in the Project area and face the highest risk of harm from the proposed survey: • humpback whales, which migrate through the area between June and November (inclusive); • sperm whales, beaked whales and other odontocetes that frequent offshore waters; • large migratory pelagic fish and shark species that show seasonal association with Child's Bank and Tripp Seamount;	potential mortal injury into perspective), adopting the precautionary principle as is required when undertaking such impact assessments, and taking into account the sensitivity of receptors present in southern African waters. Given all of the evidence, the conclusion reached for the various assessments is that impacts are either of low or very low significance. The Noise impact on plankton is assessed in Section 9.3.1.1.7 of the BA report. The reconnaissance permit area is located far offshore (120 km at its closest point) and therefore beyond the influence of coastal upwelling, which will influence both plankton abundance and the abundance of fish species that depend on plankton as a food source. From Figures 17, 18 and 19 in the marine ecology specialist assessment it is evident that the project area lies well beyond major fish spawning and recruitment area (and therefore zooplankton and ichthyoplankton abundance). An EIA is a risk-assessment based study and is a process of evaluating the likely environmental impacts of a proposed project or development. It is not possible to provide conclusive evidence of the fact that impacts will be negligible. However, it can be stated with regards to the uncertainties and gaps in knowledge that these have specifically been taken into consideration during the assessment of the particular impacts. The confidence level of the rating has been stated and the level and type of mitigation proposed has followed the clear mitigation hierarchy presented in the Specialist reports and also the EIA Report. Accordingly, the mitigation measures proposed are deemed to be sufficient to account for the eventuality that unforeseen events or organism responses are encountered during the actual survey operations, and will ensure that there is independent oversight and feedback to ensure compliance with the EMPr.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
• leatherback turtles which frequent offshore waters in low numbers and aggregate around seamounts to feed on jellyfish; and • various pelagic Albatross, Petrel, Storm Petrel and Shearwater species (the Pisces report indicates that pelagic seabirds are likely to be relatively frequently encountered in the offshore waters of the Reconnaissance Permit area).[81] 69. A 2022 review of peer-reviewed literature on the physiological, behavioural and ecological impacts of the 3D seismic survey activities on marine wildlife[82] ("Harris Report", attached marked Annex B3) found that the type of sound emitted during seismic surveys has been directly linked to physical damage to marine animals, including soft tissue trauma damage, emboliems, damage to organs used in balance and orientation, concussions, haemorrhaging, decompression sickness and both temporary and permanent threshold shifts to hearing ability. The Harris Report also found that some species display physiological stress responses and behavioural changes to seismic activities, such as moving away rapidly, diving or remaining still. These responses are likely to increase their energy consumption and energy costs, reduce their time to forage, and/or affect their vulnerability to predation, thus having negative impacts on the survival of individuals (especially young or compromised animals) as well as the overall population growth and survival of a species (especially for threatened species that are already at risk of extinction). **Acoustic Modelling**	The extent of the TGS survey area is substantively different from that applied for by Searcher in 2021 and which was the focus of the Harris (2002) review. The TGS Application Area is located further from shore and avoids many of the identified sensitive areas and sensitive times of the year. A team of similarly qualified specialists considered the proposed activity, identified and assessed potential impacts, and where applicable made recommendations to manage and mitigate the impacts. All impacts assessed can be reduced to a medium or low significance with the implementation of management and mitigation measures described in the BA report and accompanying EMPr. Please refer to Section 9.3.1 of the BA Report for the assessment of the potential impact on marine fauna (including impact on humpback whales, southern right whales, leatherback turtles, African penguin, and cape fur seal) in the context of the proposed activity. The Appellant's submission that the Acoustic Modelling, is largely a desktop assessment is correct. However, it cannot be stated that the model failed to provide meaningful information as is claimed by the Appellant. The technical noise report relies on predictive modelling to predict the noise impacts associated with the seismic survey. In order to refine and confirm this information, the underwater noise modelling study recommends that "Baseline noise measurements can provide useful information (prior to operations) when interpreting underwater noise predictions for the introduction of a new noise source. As such, it is recommended that underwater noise measurements be implemented

[82] Harris, Olbers & Wright, *Report on Scientific Basis for concerns of significant harm inflicted to marine wildlife by 2D and 3D seismic surveys on the South and West Coasts of South Africa* (14 January 2022).

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
70. The Appellants submit that the underwater noise modelling was largely a desktop study rather than a meaningful examination of the acoustic harms that seismic surveying will have. 71. The acoustic modelling failed to provide meaningful information in several ways: 71.1. The model should have included in situ testing to 'ground truth' the modelling and accurately determine the potential noise impacts associated with various aspects of the proposed 3D seismic survey (sound in the ocean is affected by pressure, salinity, temperature and temperature gradients, and can travel many kilometres from the source). 71.2. The model should have assessed the impacts of noise on all species (different species have different sensitivities to noise) during the environmental impact assessment process (not ex post factor). 71.3. The assessment should include (but not be limited to) potential impacts on the migration of snoek (a species that is important to the livelihoods of small-scale fishers) and juvenile turtles (which are significant from a biodiversity perspective given their endangered status) that are in turn dependent on other species. **Heightened Legislative Requirements are Not Considered for Critical Biodiversity Areas (CBAs), Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs)** 72. The National Environmental Management: Biodiversity Act, 2004 ("NEMBA") provides for ecosystems that warrant special conservation attention. These include ecosystems identified as Critical Biodiversity Areas ("CBAs") or Ecological Support Areas ("ESAs") in a bioregional plan, biodiversity sector plan or provincial spatial biodiversity plan.	that would include the deployment of underwater sound monitoring equipment to establish an actual baseline prior to the commencement of the survey and then operational levels of noise during the survey." The migration of snoek has been described in Section 8.5.3.10 of the BA Report. Additionally, the impact of the proposed activity on juvenile turtles is described detail in Section 4.3.3 (Impacts of Seismic Noise on Turtles) of the Marine Ecological Assessment. It is also already recommended in Section 9.3.4.2 of the BA Report as well as the EMPr that TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. The NEM:BA, NEM:PAA and NEM:ICMA are all identified as key pieces of legislation applicable to the proposed project in Section 4 of the BAR. Furthermore, the BAR goes on to discuss CBAs and ESAs in Section 6.2 – CBA 1 indicates irreplaceable or near-irreplaceable sites that are required to meet biodiversity targets with limited, if any, option to meet targets elsewhere, whereas CBA 2 are "best design sites" and there are often alternative areas where feature targets can be met; however, these will be of higher cost to other sectors and / or will be larger areas. Activities within these management zones are classified into those that are "compatible", those that are "not compatible", and those that have "restricted compatibility". Non-invasive (e.g. seismic surveys) and invasive (e.g. exploration wells) exploration activities are classified as having "restricted compatibility". Activities with restricted compatibility require a detailed assessment to determine whether the recommendation is that they should be permitted (general), permitted subject to additional regulations (consent), or prohibited, depending on a variety of factors. Petroleum production is, however, classified as "not	

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
73. The Appellants contend that the Minister ignored the critical importance of NEMBA, NEM:PAA and relevant provisions of NEM:ICMA in terms of protecting and conserving the identified CBAs within the survey area, as well as the EBSAs and MPAs. At the very least, the value of these areas and the extent of potential negative impacts of exploratory activities on these areas should have been considered. The BAR failed to provide any assessments for the CBAs contained within the Application Area or the EBSAs and MPAs that are adjacent to the area. CBAs 74. The FBAR failed to meet even minimal standards of providing a "detailed assessment" and relevant mitigation in order to protect irreplaceable and near-irreplaceable CBAs from the intense and chronic blasts of the seismic survey. In fact, the Sound Transmission Loss Modelling report makes no reference to critical biodiversity areas. 75. FBAR acknowledges that there are several CBAs within the Application Area itself: *The Application Area overlaps with areas mapped as Critical Biodiversity Area 1 (CBA 1): Natural and Critical Biodiversity Area 2: (CBA 2) Natural. Approximately 32.25 % of the proposed 3D acquisition area is covered by CBA 1 and CBA 2 Natural, 0.22% by CBA 1 and CBA 2 Restore, and 1.75% by ESA (see Figure 91).*[83] 76. CBA 1 are irreplaceable or near-irreplaceable sites that are "required to meet biodiversity targets with limited, if any options to meet targets elsewhere."[84] CBA 2 are best design sites where there may be alternative areas where biodiversity targets can be met at a higher	compatible" in CBAs, but may be compatible, subject to certain conditions, in ESAs. Seismic surveying is not only used for petroleum and natural gas exploration and development. It is also used for development of offshore wind, geothermal energy, and low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes. Therefore the CBA areas are not considered no-go areas for the purposes of seismic survey activities. In addition, the National Coastal and Marine Spatial Biodiversity Plan for the coast and ocean around the South African mainland states that petroleum production may be possible in CBAs using lateral drilling or other techniques that do not result in biodiversity impacts. According to the plan if significant petroleum resources are identified in these areas the selection of the site as a CBA could be re-evaluated, although this would require alternative CBAs to be identified to meet biodiversity targets. The potential impact on MPAs, CBA's and EBSA's is specifically noted in the BAR. A buffer of at least 5 km is recommended around MPAs, as stated in the EMPr. No buffer requirements are proposed by the marine fauna specialist for CBAs or ESBAs as the impact on these areas is expected to be low – negligible. Section 8.6 of the BAR presents the proximity of the planned activities in relation to ecologically or biologically significant areas. There is one Ecologically or Biologically Significant Marine Area (EBSA) overlapping the application area, and this was considered through the selection of the L1 point in order to gauge the effects on the Tripp Seamount to the

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
cost or requiring the allocation of additional area to achieve the targets.[85] 77. The FBAR recognizes that the exploration activities, including seismic surveys, are classified as having restricted compatibility with CBAs, which require a "detailed assessment to determine whether the recommendation is that they should be permitted (general – as is the case for this assessment), permitted subject to additional regulations (consent), or prohibited, depending on a variety of factors."[86] The BAR fails to even identify the unique and irreplaceable features of the CBAs in order to be able to assess whether this activity should be permitted. 78. CBA areas have been identified and set aside, and resources have been invested, in order to protect these biologically critical habitats and the marine species that depend on them. Seismic surveys will run directly over these critical biodiversity areas designated as irreplaceable and near-irreplaceable, causing severe and potentially irreversible impacts. 79. The FBAR has failed to look in detail at the CBAs, understanding why they were identified as critical biodiversity areas, and then propose specific mitigation measures in order to make an informed assessment as to the "restricted capability." <u>EBSAs and MPAs</u> 80. The underwater Sound Transmission Loss Modelling report conducted for the BAR indicates in its introduction that the proposed survey areas are adjacent to a few Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs) including Childs Bank and Shelf Edge, and Cape Canyon and	north. A number of Marine Protected Areas (MPAs) are located adjacent to the proposed survey areas. Section 9.3.1.1.2 of the BAR identifies and assesses the potential impact on Cape Fur Seals. Figure 37 in the marine ecology specialist assessment illustrates the foraging ranges of seals on the West Coast from tracking data. From this it is evident that the survey area lies offshore of these foraging ranges. Additionally, suitable mitigation measures have been proposed to monitor for and protect the seals should they be encountered during the survey in Section 9.3.1.1.2 of the BAR. Section 9.3.1.1.1 and Appendix 3-5 of the BAR identifies and assesses the potential impact on beaked and other whales. This includes a description of the potential impact on: • Physiological injury and mortality; • Behavioural avoidance; • Masking of Sounds and Communication; and • Indirect impacts due to effects on predators or prey. Section 9.3.1.1.1 of the BAR then goes on to state that *"The potential impacts cannot be eliminated due to the nature of the seismic sound source required during surveying. The proposed mitigation measures, which are essentially designed to keep animals out of the immediate area of impact and thereby reduce the risk of deliberate injury to marine mammals would reduce the intensity of most impacts to medium, and the residual impacts will reduce to low consequence and LOW significance, except for the effects on prey which remains of VERY LOW significance."*	

[85] BAR at 162.
[86] BAR at 162.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Associated Islands, Bays and Lagoon.[37] The BAR expands that list adding important areas such as the Benguela Muds MPA, Robben Island MPA, Southeast Atlantic Seamounts MPA and additional MPAs "that fall within the broader project area."[38] The Bar also identifies and describes eight EBSAs, including transboundary relevant to the seismic survey area.[39] 81. Although these protected areas do not fall within the seismic survey area itself, the nature of seismic survey will cause impacts on the habitats and the marine species that these areas are meant to protect. These include endangered and protected species, breeding areas, sensitive and vulnerable habitat, resident whales, and many other features which make the spaces fragile and sometimes slow to recover, which has warranted their protection. 82. The FBAR makes no effort to identify impacts to these sensitive areas and to mitigate the potentially irreversible harms that the seismic survey will cause. As noted above, the sound from seismic surveys can travel hundreds of kilometres and will penetrate into the MPAs and EBSAs. Further, the seismic surveys will increase the ambient noise beyond the survery area. The chronic blasting every 6-20 seconds for months (70 days) will cause behavioural disturbances and possibly more damage to these sensitive areas, which the BAR did not take into account. **Cape fur seals** 83. In South Africa, since October 2021, thousands of dead and/or dying Cape fur seals, have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely	Section 9.3.1.1.5 of the BAR identifies and assesses the potential impact on pelagic fish. It was concluded that the location of the Application Area well to the west of the 'ring-fenced' area and proposed mitigation measures, which are essentially designed to keep animals out of the immediate area of impact and thereby reduce the risk of deliberate injury to fish, reduces the intensity of the impacts relating to physiological injury / mortality to medium, the residual impact will reduce to low consequence and be of LOW significance. All other impacts on fish remain of LOW significance. Avoidance effects or behavioural alterations from seismic surveys involving many fish species do not automatically imply risk factors and thus do not necessarily cause a disturbance to the fishery (McCauley et al., 2000). A recent large-scale experiment conducted by Meekan et al. (2021) in Australia showed no short-term or long-term effects on the abundance or behaviour of demersal fish assemblages in response to a commercial seismic source. This suggests that seismic surveys have little impact on demersal fishes. Other studies that found no evidence of significant changes in catch rates or fish abundance include Hassel et al. 2004, Picket et al. 1994, Miller and Cripps 2013 and Thomson et al. 2014. Noise modelling was undertaken for the proposed survey and the transmission of sound at various threshold levels was taken into account. In terms of the Russell Report, inputs from the fisheries specialist points to the fact that tuna catches globally were under stress mainly from fishing effort and also due to climate variability. In fact, the data, if interrogated further, shows that the variability in catches in Namibia

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
accepted reason. Activities associated with the Project could further pressure this species by physically harming individual seals, and by disrupting the seals' food supply. 84. The Pisces Report states that Cape fur seals are unlikely to be found in the project area, citing map that shows generalized foraging areas that extend nearly exactly to the edge of the reconnaissance area.[90] However, the report also states, "[s]eals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles (~220 km) offshore,"[91] meaning a large part of the reconnaissance area is well within the foraging range of Cape fur seals. Moreover, the Based on the questionable assumption that Cape fur seals are unlikely to occur within the reconnaissance area, the Pisces Report authors deemed their sensitivity to the proposed seismic operations to be "LOW," in spite of the finding that "The potential impact of physiological injury to seals as a result of seismic noise is deemed to be of HIGH intensity."[92] **Whales and dolphins** 85. There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.[93] 86. The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the	were more associated with operational dynamics of the Namibian fleets and their licensing conditions that had reduced their effort (as South African vessels were not permitted to fish in Namibian waters). Cumulative impacts are assessed in Section 9 of the EA report. For both technical and commercial reasons, it is unlikely that concurrent seismic surveys will be undertaken in the same area during the same survey window. However, the cumulative impacts associated with multiple surveys was assessed and detailed in Section 9.3.5 of the EAR. Section 9.3.5 of the EA Report states that "three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. This relates to the large pelagic long-line sector only, and only in the event that all three surveys are undertaken simultaneously. It should be noted that the seismic industry typically avoids simultaneous surveys occurring in close proximity to each other as this has the potential to degrade the quality of the recorded survey data. Other cumulative impacts are all expected to be low after mitigation is applied – therefore overall cumulative impacts are considered low post-mitigation. It should also be noted that of the three potential surveys cited by the Appellants, the GX Technologies survey should be disregarded as the company went into liquidation in 2022. The appellants' contention that up to 30% of the revenue generated by the impacted fisheries would be lost during the 70 day period is unsubstantiated and vague for the following reasons:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.[34] **Fish** 87. The BAR downplays the impacts of seismic surveys on fish and the fisheries they support, particularly in the case of the large pelagic longline fishery and the tuna pole-line fishery. While the BAR assesses the exclusion of fishing vessels due to temporary safety zones during seismic surveys, it fails to adequately assess the actual impacts of seismic activities on the target fish species themselves, both in the short and long-term. During the seismic survey, fishing vessels would be required to maintain a safe operational distance from the survey vessel and streamer array, which may extend up to 6 nautical miles. The FBAR assessed the impact of potential exclusion for each commercial sector based on the affected area of fishing ground and the amount of catch reported within the Reconnaissance Permit area. Given the location of the Reconnaissance Permit application area, two high-value fisheries are directly impacted: the large pelagic longline fishery (targeting tuna, swordfish and shark) and the tuna pole-line fishery. 88. The FBAR concluded that the Project's activities will result in exclusion to fishing grounds for at least the large pelagic longline fishery. The FBAR states that "[t]here is a high probability that the large pelagic longline sector (targeting tuna, swordfish and shark) will experience loss of access to fishing ground over the duration of the	• The four-month window is proposed to coincide with the period of lowest activities for the fisheries that operate in the potentially affected sectors; • It should further be noted that the survey will not be undertaken over the entire tuna fisheries area or the whole application area at the same time and will thus not lead to a complete shutdown of the fishing activities in the pelagic longline sector during the 70 day period of the survey; and • The mitigation measures included in Section 9.3.2 of the BAR provide for avoidance of the peak fishing periods and, furthermore, for the establishment of clear communication channels to be established with the other users of the survey area and to ensure that the disturbance within this sector is reduced to the absolute minimum. The impact on the affected fishing sectors was assessed to be of low significance and short duration and it could thus not be stated that "The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna." Impacts of cumulative sound exposure on marine mammals are evaluated using disturbance and injury threshold, defined as temporary threshold shifts (TTS) and permanent threshold shifts (PTS) (Southall et al. 2019). The audibility of a noise pertains only to the perception or detection of a sound above background levels of ambient noise. The thresholds established by Southall et al. (2019) are internationally regarded as standard references for environmental impact assessment of underwater noise. Although the modelling report doesn't specifically reference the CBA areas, the purpose of the modelling was to model the likely sound transmission and contours. The outputs of the model were then

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
proposed 70-day survey," and that [t]he impact of exclusion is assessed to be of high magnitude."[95] 89. In terms of noise impacts to the target fish of the large pelagic longline fishery and the tuna pole-line fishery, the Pisces Report acknowledges that "[s]eismic activities have been predicted to possibly affect the migration patterns of tuna leading to substantially reduced catches of albacore and southern bluefin tuna in southern Namibia and the Great Australian Bight, respectively,"[96] yet ultimately the Report concludes that "[a]s there is currently a dearth of information on the impacts of seismic noise on truly pelagic species such as swordfish and tuna (Evans et al. 2018; Webster et al. 2018), links between changes in migration patterns and subsequent catches thus remains speculative."[97] The FBAR thus maintains that potential impact on individual fish behaviour is of MEDIUM consequence and that "the residual impact due to seismic noise is considered to be of LOW NEGATIVE significance for the large pelagic longline and tuna pole-line sectors."[98] 90. Overall, the FBAR concludes that with mitigation (timing of the surveys to avoid peak fishing periods), the following overall impact significance: Based on the combination of extent, duration and magnitude of the impact, and considering the high probability that the impact would occur, the overall significance of the impact is considered to be MEDIUM	considered and assessed by the marine ecology specialist who specifically considered the CBA areas. The Appellants' submission that mitigation measures proposed only focus on marine mammals, is not substantiated by the large number of mitigation measures as detailed in Section 9 and 11.4 of the BAR. The use of infra-red cameras was discussed during the various public meetings held during the BAR review phase and included in the Public Participation Report in Appendix 2. It should further be noted that the Appellants' commented on the lack of inclusion of infra-red cameras during the BAR review phase, and subsequently the EAP included this as a specific mitigation measure in the final BAR. It is therefore strange that the Appellant now disputes the use of this technology and lists this as a supporting factor in this grounds of appeal. The Noise impact on plankton is assessed in Section 9.3.1.1.7 of the BA report. The study by McCauley et al. (2017) generated significant public attention, but the paper has not been widely accepted by the scientific expert community as the findings are considered severely flawed. Details on the independent reviews of the paper are provided in the EnerGeo response to a publication by the Scientific Advisory Group on Emergencies (SAGE). Follow-up studies by Richardson et al (2017) failed to conclusively demonstrate discernible effects on zooplankton biomass on a regional scale and Fields et al. (2019) detected no significant behavioural differences in the copepod species *Calanus*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
NEGATIVE. Due to the low probability of the operations of the tuna pole-line sector within the Reconnaissance Permit area, the overall significance of the impact on the sector is considered to be LOW NEGATIVE. 91. The EBAR fails to adequately assess the vulnerability of the targeted fish species (including tuna and sharks) to noise impacts, and any decision based on it would be unreasonable. This is a major flaw because many of the large pelagic fish and shark species likely to occur in the offshore regions of the Orange Basin are considered globally 'Vulnerable' (e.g., bigeye tuna, blue marlin, Oceanic Whitetip shark, dusky shark, great white shark, longfin mako), 'Endangered' (e.g., shortfin mako, whale shark) and 'Critically Endangered' (Southern bluefin tuna). 92. The impact on fish assemblages is difficult to interpret, due to multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. A global review of the effect of seismic activities on fish and invertebrates acknowledged the limits of the current research due to experimental designs used or due to the focus on single species during investigations. A key concern is a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys that have been previously identified may be reflective of underestimation or overestimation and would depend on the type of interaction (synergistic, additive, or antagonistic).[99] 93. Sounds pollution from seismic surveys may have a wide range of effects on fish species. Exposure to intense sounds can result in mortal injury, but over longer distances issues are associated with sounds that are detectable by fish and which may affect their behaviour, causing them to move away from their migration routes, flee important habitats in which they feed or breed, interfere with	*fimmanchilus* based on distance to the source or control vs. exposed groups. The reconnaissance permit area is located far offshore (120 km at its closest point) and therefore beyond the influence of coastal upwelling, which will influence both plankton abundance and the abundance of fish species that depend on plankton as a food source. From Figures 17, 18 and 19 in the marine ecology specialist assessment it is evident that the project area lies well beyond major fish spawning and recruitment area (and therefore zooplankton and ichthyoplankton abundance); Figure 27 shows the area in relation to Cape Gannet and African Penguin distribution; Figure 37 shows the area in relation to seal foraging areas and Figure 47 shows the area in relation to virtual turtle hatchling trajectories. The survey area in relation to various marine mammal distributions is also provided and in all cases it is evident that interaction with marine fauna in those offshore waters should be minimal. The impact assessment shows that these impacts are of a medium-low significance even before any mitigation measures are applied. Regarding the supplementation with respect to the operating hours of the PAM monitoring: This would require the survey to likely run over two (or more) seasons. This is not only not cost effective for the seismic operator, but would extend the duration of the acoustic impacts (and others) associated with surveying. Considering that the survey area is located within the major shipping lanes and that ambient sound levels (dominated by the noise of vessels) will be persistent throughout the day and night, it seems more appropriate to undertake the survey in as

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
their communications, affect reproductive behaviour (where sound is used to attract mates and facilitate spawning), or prevent or mask the detection of other biologically important sounds. Because of these many-pronged affects, seismic surveys can have compounding negative impacts on marine fish. 94. In his expert affidavit filed in a recent seismic survey case,[100] Dr Alexander Claus Winkler provided testimony regarding evidence of direct, lasting behavioural effects of seismic surveys on the rhythmic behavioural foraging patterns of cod in the North Sea. Winkler points out that both hake and snoek perform rhythmic diel foraging migrations off the seafloor at night and onto the seabed during the day. Given that seismic surveys are conducted both during the day and night, it is likely that these benthic fish species will migrate higher up the water column at night, bringing them within distances that may expose them to direct injury and mortality impacts from seismic surveys. It is noted that the Pisces report indicates that species most likely to be found in the area of interest include large migratory fish (such as tuna, billfish and sharks), many of which are considered threatened by the IUCN due to overfishing.[101] 95. In addition, contrary to the EBAR's conclusions that there is only LOW NEGATIVE significance for the large pelagic longline and tuna pole-line sectors,[102] a 2018 desktop survey of South Africa fisheries impacts from seismic surveying by Namibian fisheries expert David Russell ("Russell Report") concluded the following: [W]here there are cumulative impacts from repetitive surveys in the same area, as has occurred off Southern Namibia tuna fishing grounds, where	short a time as possible, in which case night-time operations are necessary. The studies undertaken internationally over the past ~70 years on the impacts of noise on marine fauna (of which some 400 peer-reviewed publications have been summarised and cited in the marine faunal specialist study) have concluded that the effects of underwater sounds vary substantially and depend on a wide variety of physical and biological factors. When writing articles on the effects of seismic acquisition on marine fauna it is therefore not difficult to bias the literature cited to either demonstrate detrimental and irreversible impacts or only very limited impacts, depending on the personal view of the author(s) and/or the targeted readership. The marine faunal assessment has made efforts to present published results objectively, and nowhere claims that acoustic surveys do not result in impacts. Injury is likely at very short range, with behavioural disturbance occurring over greater distances. The final significance ratings are determined using information from the peer-reviewed literature together with the noise modelling results (which put the threshold distances from the source array to mortality and potential mortal injury into perspective), adopting the precautionary principle as is required when undertaking such impact assessments, and taking into account the sensitivity of receptors present in southern African waters. Given all of the evidence, the conclusion reached for the various assessments is that impacts are either of low or very low significance. It is not disputed that MMO sightings are not 100% efficient. Various approaches have been adopted over the years to improve observer

catches have severely declined since 2011, and in 2017 dropped off to non-commercial catch rates, there is the ominous possibility that the tunas change their migration path. Environmental factors such as El Nino appear to also have contributed significantly, but combined with regular seismic surveys, the environmental signals are potentially devastating.[103] 96. There is a possibility that up to three seismic surveys (Searcher, TGS, and GX Technologies) would take place simultaneously in the area, which would further increase geographic exclusion of the fishery. If multiple 3D seismic surveys were not undertaken simultaneously, then sequential surveys in the same area would prolong the loss of access to the pelagic longline sector and duration of seismic impacts to fisheries. Yet the FBAR does not directly assess the impacts of simultaneous surveys on the fisheries. 97. The FBAR concludes, without citing any evidence, that after months of up to three simultaneous seismic surveys in the pelagic longline sector, "[o]nce completed there is not expected to be any residual impact."[104] As noted above, the Russell report identified potential long-term impacts of repeat seismic activity on Southern Namibian tuna fisheries, with implications that tuna may change their migration patterns to avoid noise pollution.[105] The BAR fails to adequately consider or mitigate impacts to the pelagic longline sector that are both short-term (potentially closing the fishery for 70 days or longer given multiple surveys in a single year) and long-term (inflicting behavioural and migration shifts).	efficiency, particularly at night, with infra-red binoculars and mast-mounted infra-red (IR) cameras being tested. These have, however, not proven as effective as initially anticipated, due to lack of detectable temperature differences, resulting in the implementation of the 24/7 PAM surveillance. From a seismic operator's perspective, it is not feasible or cost-effective to cease airgun operations at night as this would prolong the duration of the survey possibly requiring multiple seasons to complete the acquisition. This would also add substantially to the overall survey duration and cumulative impacts.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
98. The sector had an estimated wholesale value of R124 Million in 2018, or 1.2% of the total value of all fisheries combined. For tuna pole-line, the fishery runs predominantly from November through June, while the large pelagic longline fishery runs highest from May to November.[196] The FBAR lists a proposed window of January – May for its 70-day 3D seismic survey, meaning a large fraction (up to 30% with an approximate wholesale value of R40 Million) of the fishery year stands to be excluded. Because its assessment did not adequately consider the longer-term residual impacts on the fisheries from seismic activity, this monetary loss stands to be much greater than that estimated from fishery exclusion alone. 99. The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna. Such changes in the fishery could have severe and lasting implications for communities dependent on this important fishery for many years to come and should have been included in the impact assessment. 100. The FBAR states that "[t]he zones of TTS [temporary threshold shift] effect for fish species with and without swim bladders are predicted to be within 3.5 km from the survey lines for the 3D survey 24-hour operation scenarios considered."[197] This predicted zone of TTS for fish both with and without swim bladders is a gross underestimation and based on minimal and non-regional specific data, including data from riverine 2D seismic activity on freshwater species (e.g. Popper et al., 2006). As the Capricorn Report admits, "[t]o date there have

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
been no studies focused directly on the [fish] species found locally."[108]		
101. Most of the mitigation measures proposed in the BAR are designed to minimise impacts to marine mammals. As admitted in the Pisces Report, vastly less is known about how such mitigation measures alleviate sound impacts experienced by marine fish species.[109] Large pelagic fish (e.g. tuna, sunfish, or sharks) would not be detected by PAM (which would be tuned for marine mammal vocalisations) and would not likely be detected visually at night by observers or using an infrared thermal imaging camera (since cold-blooded fish, as opposed to warm-blooded mammals, do not have high enough temperature differences from the water).		
102. The FBAR further fails to provide evidence that infrared thermal imaging is effective as a mitigation measure.		
103. TGS takes no preventative mitigation measures to minimise impacts to marine fish species during 3D surveying and has a single and insignificant mitigation measure (7.1) to shut down seismic shooting in the case the following is observed: "mass mortalities of squid and fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO (marine mammal observer) to be as a direct result of the survey."[110]		
104. Although it has been suggested that the sound energy from air guns may harm fish species with swim bladders and those without, there are very few studies directly examining the potential effects on fish physiology or behaviour, and even fewer focusing on pelagic fish species. Unknown impacts are not the same as no impacts, and the

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
precautionary principle should be invoked. There are significant knowledge gaps regarding the impact of 3D seismic surveys on marine fish species, particularly those that would be impacted by the Project. Specifically, there is currently not enough information about the fish species in the area or their response to sound to be able to make any meaningful assessment of the impacts. Therefore, the precautionary approach set out in NEMA suggests that this lack of knowledge should weigh against the proposed 3D seismic surveying in a vital and valuable offshore fishery. **Zooplankton** 105. The FBAR disregards the precautionary approach at every step in the analysis of impacts on plankton, which it concludes does not warrant mitigation measures and will have a medium pre-mitigation impact, yet a very low residual impact.[111] Yet, as demonstrated below, there is a significant concern that the BAR underestimates the impacts of seismic surveys on plankton, which form the base of the ocean food chain. 106. The FBAR does not provide actual data to demonstrate that there is not significant or even medium plankton abundance in the survey area. The BAR "expects" that plankton abundance to be low with seasonal peaks may occur associate with MPAs.[112] Yet, the surveying is meant to have temporal overlap with speak spawning products of commercially important species.[113] 107. Studies by McCauley et al. (2017) referenced in the Pisces Report indicates that seismic blasts may kill various species of zooplankton in Australia at distances of up to 1200 m from an airgun[114], and more

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
recent research shows lethal and behavioral impacts to zooplankton from airgun discharges.[115] Still, other studies (Fields et al., 2019), report no measured mortality or sublethal effect on copepods at distances >10 m from a seismic blast in Norwegian waters.[116] And other studies (Richardson 2017) found "substantial impact of seismic activity on zooplankton populations on a local scale within or close to the survey area."[117] While noting that zooplankton mortality can be difficult to assess in the field (in situ) and that realistic conditions are very difficult to reproduce in a laboratory setting, nevertheless these highly contradictory results suggest that effects may be variable and highly dependent on zooplankton species and/or marine geographical area. Research should be undertaken to survey the current literature on zooplankton types in the Benguela Upwelling Zone and better link this knowledge to the airgun impacts literature available. The BAR fails to take these steps, making it impossible to assess the impacts of seismic surveys to the zooplankton communities underpinning the food webs that support fish, marine mammals, and fisheries. 108. As noted, zooplankton forms the base of many important food webs in the marine environment. Depletion of zooplankton could thus have an impact on food for their predators (such as fish) as well as impact fish eggs and larvae (ichthyoplankton) with potential local impacts on species important in fisheries. This damage to zooplankton as found by studies over 1km away (McCauley 2017) and within 15km (Richardson 2017) from the survey array raises concern

[117] Rice Supporting Expert Affidavit at para. 29 (restating the conclusion from the study's authors: "We found there was substantial impact of seismic activity on zooplankton populations on a local scale within or close to the survey area, with a maximum decline of 22% in zooplankton populations in the survey area, 14% within 15 km of the survey area.").

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
that a 500m buffer for other animals that are unable to move away from the sound, is far too small to ensure that damage is not inflicted (even if they were able to evade it).[118] **The proposed mitigation measures are inadequate to prevent unacceptable harm to marine life** Simultaneous Surveys 109. The FBAR proposes the use of a 40 km buffer between vessels during concurrent simultaneous surveys (p. 211) as a mitigation measure, relying on "advice from the US Department of Interior (2014)." The purpose of the buffer is to mitigate "the cumulative impacts of three potential surveys occurring concurrently."[119] The 40 km buffer mitigation measure, first proposed in the United States, originally purported to avoid harassment of marine mammals during simultaneous surveys. This was expected to be achieved through a distance between vessels that would provide a corridor where "airgun noise is below [harassment] thresholds and approaching ambient levels such that animals may pass through rather than go larger distances to go around the survey vessels."[120] However, the mitigation measure neither provides a corridor below harassing levels of acoustic noise for marine mammals between vessels seismic surveying, nor does it mitigate cumulative impacts as portrayed in the FBAR. In fact, the mitigation measure is not even used in the US, making the FBAR reliance upon this measure deeply flawed. 110. First, the 40 km buffer is based upon a threshold of 160 dB for harassment, a standard that the U.S. government has since abandoned as appropriate to provide adequate protections. For

example, the US government found in 2018 in reviewing harms to marine mammals during oil and gas geophysical surveys that, "[s]tudies of marine mammals in the wild and in experimental settings do not support" use of a single 160-decibel threshold and that "that an approach reflecting a more complex probabilistic function is better reflective of available scientific information," because it "takes the fundamental step of acknowledging the potential for . . . harassment at exposures to received levels below 160 [decibels]."[121] 111. Second, as noted above, scientists recognize that this 160 decibel threshold is not supported by science. In addition, in his expert declaration Dr. Nowacek noted that "seismic surveys can disrupt important behaviors in baleen whales at exposure levels far below the 160 dB threshold".[122] 112. Third, the application of a 40 km buffer as a wholesale solution for simultaneous surveys is incompatible with even the 2014 Department of Interior document that the BAR is relying upon. In fact, the US Government prohibits the use of a 40 km buffer as a general mitigation measure. It instead found that new science demonstrated that "airgun noise can be detected at great distances from the sound source, such as across ocean basins," and that therefore, the mitigation measure must be considered in the site-specific context and include any new information at the time as well as "any potential aggregate effects from existing permitted		

[121] See Taking and Importing Marine Mammals; Taking Marine Mammals Incidental to Geophysical Surveys Related to Oil and Gas Activities in the Gulf of Mexico, 83 Fed. Reg. 29,212, 29,247-48 (June 22, 2018).

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
surveys."[123] The BAR does none of this analysis and in fact proposes potentially reducing the buffer zone.[124] 113. This mitigation measure has been proven to be scientifically unsound and ineffective and uses an approach inapposite with the base documents upon which the BAR relies, inconsistent with the current practice of the US Government, and inconsistent with the science. Therefore, there is no basis for the BAR to conclude that a 40 km buffer will mitigate cumulative impacts of concurrent seismic surveys. <u>Inefficacy of Proposed Mitigation Measures</u> 114. Several of the proposed mitigation measures are ineffective to mitigate the harms related to the impacts of the seismic surveys. Consequently, the significance of the post mitigation impacts are understated, exposing marine species, in particular marine mammals and to more injury and harm than indicated in the conclusions of the BAR. 115. Soft Starts and Ramp Ups: Harris *et al.* found that the soft starts are "are likely to reduce the impact for highly mobile large animals, this is unlikely to be adequate for the many species that are prevalent in the area over the austral summer months and are unable to avoid the array or leave the area due to their lower mobility, such as smaller turtles, penguins, invertebrates, some fish species and zooplankton."[125] Moreso, Dr. Nowacek found that soft starts or ramp ups do not protect highly mobile cetaceans, finding them "inadequate to protect cetaceans present year-round or deep-diving

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
beaked whales."[126] Dr. Nowacek further expounded "there has been no experimental confirmation that this procedure is broadly effective at reducing overall exposure."[127] In considering a situation where soft starts or ramp ups worked perfectly, Dr. Nowacek found that "this mitigation measure would reduce only the number of injuries incurred in the vicinity of the seismic vessel and does not address at all the larger body of effects."[128] 116. Observers: Harris *et al*. explain that visual observers, although important to mitigation, have deficiencies, which brings into question the SAR's conclusions regarding the level of impacts post-mitigation: *"The finding of observer efficiency (from a scientific monitoring study conducted during the 2018/19 and 2019/2020 seasons on the humpback whales on the east coast) suggests that even with trained observers up to 44% of humpback whales in an area went undetected. This casts doubt on the effectiveness and success of Marine Mammal Observer (MMO) sightings of the largest species (humpbacks) as a mitigation measure, indicating that it is most likely that whales go undetected. Furthermore, the detection rate for smaller species, such as dolphins, seals, turtles and flightless birds (penguins), would be expected to be much lower, obviating the effectiveness of visual observations to prevent harm to these species."*[129] 117. Dr. Nowacek reiterates that the mitigation measure of visual observers is "inadequate to protect cetaceans present year-round or deep-diving beaked whales."[130] Dr. Nowacek further explains that the use of visual observers to detect whales "is imperfect at best"

because low light and other poor visibility conditions (such as fog or high-sea states) impair the ability to spot whales and, as Dr. Nowacek goes into further detail, even in ideal conditions it is very difficult to spot whales.[131] This is echoed by Harris et al. stating the "efficacy of a MMO is likely to be low due to the nature of the offshore marine environment in the survey area (frequent high swells and winds affecting surface visibility), putting species who are missed by MMOs and PAM operators at extreme risk, particularly at night or during adverse weather conditions."[132] 118. Passive Acoustic Monitoring (PAM): Harris *et al.* discuss how "the reliance on observers to do visual sightings to supplement the PAM monitoring during the day, as a mandated mitigation measure, necessitates questioning the acceptability of continuing with survey activities at night. If the visual observations are useful (perhaps sighting large animals around 65% of the time) in addition to PAM, then relying on PAM alone at night cannot be an effective mitigation measure. The authors express the opinion that surveys should not occur between sunset and sunrise each day if a real attempt of maximum avoidance of cetaceans is the objective of this mitigation measure."[133] 119. Dr. Nowacek discusses as well the limited benefit of PAM. With PAM, "whales will not be detected even when present if they are quiet or not vocalizing or if background noise is too high." Dr. Nowacek also noted that "studies show that baleen whales cease vocalizing in the presence of even low levels of seismic survey noise."[134]

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRS/PASA
120. The FBAR's attempts to address this shortcoming in mitigation by equipping MMOs "with infra-red cameras in order to observe mammals at night."[135] However, this is an undeveloped technology for spotting cetaceans. It is not reliable, so much so that it is not typically used by scientists as part of their surveys. Further, there are questions with the scope of view, range/distance, as well as the impact of conditions on the ability to use the technology. In short, it is encouraging to bring new technologies to the table, however it requires more testing and improvement before it could be considered suitably reliable and certainly before it could be factored into the the mitigation of harms to cetaceans. **Lack of baseline noise assessment** 121. The FBAR fails to establish an acoustic baseline assessment of the area, and furthermore fails to present a plan to conduct an adequate baseline noise assessment. As part of its recommendations to minimise impacts to marine fauna, the BAR lists: Baseline noise measurements can provide useful information (prior to operations) when interpreting underwater noise predictions for the introduction of a new noise source. As such, it is recommended that underwater noise measurements be implemented that would include the deployment of underwater sound monitoring equipment to establish an actual baseline prior to the commencement of the survey and then operational levels of noise during the survey.[136] 122. The FBAR provides no guidance for the recommended baseline noise measurement, including the duration of monitoring period, or a

range or frequency for detection. This lack of detail means it remains impossible to assess if this mitigation step would meet best practice standards such as those put forward by the Marine Mammal Observers Association. 123. The current lack of a baseline assessment means that the ambient background noise considered in the noise modelling falls short of best practices. Best practice acoustical modelling entails collecting site-specific data to calibrate acoustic models that can then be applied to characterize acoustic exposure of marine fauna in a given study area.[137] **Chronic Noise Impacts** 124. The seismic survey's airguns consist of 24 active airguns that will blast sound loud enough to penetrate the seabed floor every 6-20 seconds, 24 hours a day, for 70 days. Each acute blast will create direct harms to marine species. In addition, besides the direct harm that the pulse will create, the repetitive blasting will increase ambient noise, even at a distance of 100 kilometres.[138] These two factors expose marine species to chronic noise impacts over a large distance, as the sound travels hundreds and even thousands of kilometres.[139] The EBAR fails to take into account the increased stress and behavioural impacts that this chronic noise will cause on marine species in the area of seismic surveying and beyond

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Ground 3: Failure to adequately assess cumulative impacts 125. Below is a map detailing the updated categories of Oil and Gas concessions along the entire coastline of South Africa:  Information received from Petroleum Agency SA, in line with a PAIA Request submitted by the Legal Resources Centre on 12 October 2022 126. In addition to the abovementioned map, it is noted that the BAR acknowledges that should other seismic survey campaigns be undertaken concurrently with TGS's proposed survey programme, cumulative impacts may be likely and there would be a need for alignment in planning of such concurrent operations to reduce	It is understood that ION GXT has been declared bankrupt and have ceased operations - as such, the ION GXT Reconnaissance Permit is considered to be defunct. Section 9.3.5 of the BA Report states that "three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. This relates to the large pelagic long-line sector only, and only in the event that all three surveys are undertaken simultaneously. It should be noted that the seismic industry typically avoids simultaneous surveys occurring in close proximity to each other as this has the potential to degrade the quality of the recorded survey data. Other cumulative impacts are all expected to be low after mitigation is applied – therefore overall cumulative impacts are considered low post-mitigation. The marine faunal assessment has made efforts to present published results objectively, and nowhere claims that acoustic surveys do not result in impacts. The inference is that, for these whale populations, there is no direct evidence to link the long-term negative change to population size directly to seismic survey activities. The statement is only one regarding the "lack of evidence" with respect to certain whale populations and seismic surveys. The marine fauna report recommends planning seismic surveys to avoid sensitive areas and periods for some marine fauna: Movement of migratory cetaceans (particularly baleen whales) from their southern feeding grounds into low latitude waters (June/July and late October/November), and their aggregation on the summer feeding grounds between St Helena Bay and Dassen Island from late October to late December and ensure that migration paths are not blocked by seismic operations. If possible, the survey should be undertaken from	

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
cumulative noise impacts to an acceptable significance.[140] The draft BAR notes that there are two current pending applications with PASA (Searcher Geodata and GX Technology Corporation) which both overlap the proposed TGS 3D seismic survey area, as depicted in the diagram below:	North to South to avoid these feeding aggregations. A discussion of the migration of various cetaceans is provided in Section 8.4.3.6 of the BA Report. It is unlikely that concurrent seismic surveys will be undertaken in the same area during the same survey window however the cumulative impacts associated with multiple surveys needs to be, and was, assessed. The decision-making authority did elaborate on the decision regarding whether concurrent surveys can take place. The proposed seismic activity will not automatically lead to further exploration, production, and utilisation of petroleum resources. The information to be obtained through the seismic survey will provide information as to whether they may be exploitable resources. The climate change impacts of any potential future exploration or production activities would have to be assessed as part of the associated and required Environmental Authorisation applications submitted for those projects, with due consideration of the other climate affecting activities proposed or in place at the time.

127. The BAR states that despite the difficulty in undertaking a reliable assessment of the potential cumulative environmental impacts of future seismic acquisition in the Deep Water Orange Basin (due to likely variation in the scope, extent and duration of proposed surveys), the cumulative impacts of three potential surveys occurring

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
concurrently needs to be considered. The FBAR thus includes a cumulative assessment which assumes that the three surveys (Searcher, TGS and GX Technologies) occur simultaneously during the summer survey window in 2022/23. In this event, the draft BAR indicates that: 125. Associated impacts to marine fauna would be of high intensity and extend regionally, over the short-term (assuming they take place over the same summer survey window). The impact consequence for cumulative surveys is therefore considered medium. 129. Concurrent activities could also add to the cumulative impact on fisheries. Simultaneous survey operations would result in an increase in the extent and magnitude of the impact on the large pelagic longline sector. The impact duration would remain unchanged. Three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. 130. Curiously, the BAR impact table[141] combines cumulative impacts on marine fauna and fisheries and rates the pre-mitigation environmental significance as 'medium' and the post-mitigation impact as 'low'. This does not reconcile with the preceding paragraphs which indicate with regard to cumulative impacts of three concurrent seismic surveys, an impact of medium negative

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
significance on the large pelagic sector could be expected 'both with and without the application of mitigation measures. 131. The Final BAR states regarding confounding and cumulative effects that the assessments of impacts of seismic sounds provided in the scientific literature usually consider short-term responses at the level of individual animals only, as the understanding of how such short-term effects relate to adverse residual effects at the population level is limited. The report goes on to state that data on behavioural reactions to seismic noise acquired over the short-term could, however, easily be misinterpreted as being less significant than the cumulative effects over the long-term (i.e. what is initially interpreted as an impact not having a detrimental effect and thus being of low significance, may turn out to result in a long-term decline in the population, particularly when combined with other stressors such as temperature, competition for food, and shipping noise). The report notes that confounding effects are, however, difficult to separate from those due to seismic surveys.[142] 132. The report also states that the potential cumulative impacts on individuals and populations as a result of other seismic surveys undertaken either previously, concurrently or subsequently are difficult to assess. The report indicates that a significant adverse residual environmental effect is considered one that affects marine biota by causing a decline in abundance or change in distribution of a population(s) over more than one generation within an area. The report makes reference to numerous 2D and 3D seismic surveys having been undertaken off the West Coast over the past 17 years, and relies on reported increases in the southern right whale and humpback whale populations over a time when seismic surveying frequency has increased as 'suggesting that, for these populations at

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
least, there is no evidence of long-term negative change to population size as a direct result of seismic survey activities'.[143] The assumption made that an increase in whale populations suggests that there is no evidence of long-term negative change to population sizes as a direct result of seismic activities, is questionable. This is an assumption that cannot be inferred from the facts (the increase could be as a result of any number of other external factors). 133. It cannot simply be assumed that the lack of evidence of long-term negative population changes as a direct result of seismic survey activities means that there are no negative impacts (including potentially significant impacts). In their report relating to the TOSACO EIA appeal, Harris *et al* point out that although the humpback whale population is increasing, there is evidence to suggest that cetaceans in South African waters are being affected by changes in their ecosystem and it is not well understood yet what is driving these changes and what the long terms effects could potentially be to populations.[144] Concerns noted in the report include an observed decrease in southern right whale calving success of the South African population and a strong link between foraging success and reproduction.[145] They suggest an investigation into possible decreases and/or spatial or temporal shifts in their prey availability at higher latitudes due to environmental variability. They also highlight a concern of the continued low numbers of unaccompanied adults

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
along the South African coast which could potentially have serious consequences for cow-calf pairs in relation to the country's whale-watching industry in the future. 134. The BAR states that in the 'unlikely' event that multiple surveys would take place at the same time within the same survey area, 'the risk of cumulative noise impact must be considered and is suggested to be managed'. The BAR suggests that mitigation should include maintaining a distance of at least 40 km between survey vessels 'until sufficient objective evidence is obtained that a reduced buffer distance is acceptable'. Where this 40 km buffer distance cannot be maintained, the FBAR suggests that each of the additional activities to those described in the technical noise report should be modelled or otherwise considered in terms of the cumulative noise level and with reference to the criteria described in the report.'[146] 135. However, as referred above at paragraphs 109-1113, the US Government prohibits the use of a 40 km buffer as a general mitigation measure and therefore, the mitigation measure must be considered in the site-specific context and include any new information at the time as well as "any potential aggregate effects from existing permitted surveys. This mitigation measure has been proven to be scientifically unsound and ineffective and uses an approach inapposite with the base documents upon which the BAR relies. Therefore, there is no basis for the BAR to conclude that a 40 km buffer will mitigate cumulative impacts of concurrent seismic surveys.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
136. Given the lack of certainty regarding cumulative impacts of concurrent 3D seismic survey areas, a risk averse and cautious approach should be applied by not authorising concurrent surveys and suggests that should the decision-maker ought to have refused granting the environmental authorisation. 137. In addition, the FBAR does not consider the cumulative impacts of other proposed offshore oil and gas seismic surveys, exploration and production in other Blocks within South Africa's exclusive economic zone. Having regard to the global Climate Emergency[147] and South Africa's international commitment[148] to *'working with others to ensure temperature increases are kept well below 2°C above pre-industrial levels, which could include a further revision of the temperature goal to below 1.5°C in light of emerging science'*[149] by reducing greenhouse gas (GHG) emissions, TGS's proposed 3D seismic survey would, if additional commercially viable resources are identified and developed through to production phase, inevitably add to South Africa's overall GHG emissions (South Africa's energy sector currently contributes an estimated 84% percent to the country's overall GHG emissions).[150] As a reasonably foreseeable future impact that may become more significant, especially in combination with impacts arising from similar offshore oil and gas exploration and

production activities, it is submitted that the cumulative impacts[151] of such GHG emissions need to be identified and assessed.		
Ground 4: Failure to conduct meaningful consultation with communities and local people (and in particular small-scale fishers), within the public participation process, including the Social Impact Assessment process 138.It is one of the foundational principles of NEMA that the participation of all interested and affected parties must be promoted and the participation of disadvantaged people must be ensured.[152] Section 24(4)(a)(v) of NEMA provides that interested and affected parties must be given a reasonable opportunity to participate in the environmental impact assessment process. Regulation 41(6) provides that the public participation process must be facilitated in a manner that provides all potential interest and affected parties a reasonable opportunity to comment on the proposed project. Regulation 41(2) of the EIA Regulations requires that the public participation process take into account the relevant guidelines. The 2017 Public Participation Guidelines provide that: 137.1. The level of public participation must be informed by the characteristics of the potentially affected parties.[153] 137.2. The method of communication must be an effective method that will easily reach the intended audiences.[154]	It is our opinion that the Public Participation Process was conducted in line with and exceeded the requirements of the Environmental Impact Assessment (EIA) Regulations (2014), as amended, and that the process followed was reasonable. With reference to Section 7 and Appendix 2 of the BA Report, EMS has undertaken the public participation and consultation processes in accordance with the requirements of the NEMA EIA Regulations. This process included notification and communication in three different languages, via Radio and Newspaper advertisements, site notices, posters, and direct notification; as well as public and focus group meetings within the potentially affected communities. Opportunity was provided to review and comment on the BA Report and associated documentation to be submitted to the decision maker. It should further be noted that detailed consultations with community members and leadership were conducted by the Social and Heritage Specialists to obtain the views of project affected communities and the potential social and heritage impacts of the proposed project. The applicant is not aware of any additional requests received from I&APs for further avenues or opportunities for	

[151] 'Cumulative impact' is defined in the NEMA EIA Regulations as follows: 'in relation to an activity, means the past, current and reasonably foreseeable future impact of an activity, considered together with the impact of activities associated with that activity, that in itself may not be significant, but may become significant when added to the existing and reasonably foreseeable impacts eventuating from similar or diverse activities.

[152] NEMA, section 2(4)(f).

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
137.3. The language used must provide all potential interested and affected parties a reasonable opportunity to comment without unnecessary difficulty.[155] 139. The court in *Sustaining the Wild Coast NPC*[156] has upheld this and stated: "Meaningful consultation entails providing communities with the necessary information on the proposed activities and affording them an opportunity to make informed representations"[157] 140. Coastal communities and the general public have been overwhelmed with the number of offshore oil and gas related applications running in parallel processes, particularly those which may impact the south-west and west coast of South Africa. In the month of May, I&APs have been called upon to respond to no less than four offshore oil and gas EIA processes, without taking into account legislative public participation processes for the Upstream Petroleum Resources Development Bill and the draft Marine Spatial Plans during a similar period. The EAP in the current application, SLR, has been appointed to conduct three of these parallel EIAs. 141. The table below sets out the various EIA processes, in which it is clear that multiple public meetings and submission dates are running during similar time periods:	participation. The public participation requirements and obligations of the NEMA EIA Regulations has been complied with. With Reference to the table presented in point 141 above, it should be noted that EIMS was the EAP and it is unclear whether this comment relates to this application. However, it should be stated that it is clear that the TGS process did not conflict with other concurrent processes and it is anticipated that I&APs had sufficient time to attend the extensive public consultations undertaken during the initial call to register phase, as well as the BAR Review period. Please refer to the Public Participation Report in Appendix 2 of the BAR for further details on the public consultations undertaken. It should be noted that the Ms Mostert was specifically identified as a key Interested and Affected Party (I&AP) and included in the Public Participation throughout the Basic Assessment Process. Ms Mostert's comments were captured in the minutes of the meetings included in Appendix 2-6 and 2-9 of the BAR. As requested during the public meetings, the final BAR was also made available on the EIMS website (and the datafree version thereof) post submission of the final report to the Competent Authority for adjudication and was available throughout the appeal notification period. The EAP therefore, utilized the reasonable and requested methods of communication and transparency and did not receive requests for alternative methods. It is also important to consider that the findings of the BAR were that there is unlikely to be significant adverse impacts. With reference to Section 7 and Appendix 2 of the BA Report, EIMS has undertaken the public participation and consultation processes in

TEEPSA Block 5/6/7: exploration drilling	SLR Consulting (Pty) Ltd	June – July 2022	7 December 2022 12 May 2023		The recommendation of the SIA is that, should the project be approved a representative from TGS must consult with leadership of the community to determine how the communities should be consulted with in future – that is, what is the way the community members prefer to be consulted with for provision of commencement notification and/or daily updates to advise on survey schedules, communication in respect of the proposed research outcomes, etc. The recommendation to include further consultation as part of the conditions of authorisation intends to ensure that the consultation process goes further than just the EIA process, but is continued throughout the entire process, regardless of the outcome. This will assist communities and people on the ground to make informed decisions about technical matters. The intention of the recommendation is not for this condition to be suspensive or determinant on the ultimate decision but rather to function as an additional management/ mitigation measure to be implemented post approval to reduce the significance of the identified impacts and further enhance the community engagements

142. Many members of the public will be confused by the various applications, with different processes, slightly different due dates, slightly different applicants all being branded the same with the same EAPs conducting similar EIA processes. It is inconceivable that affected coastal communities are able to respond to each of these processes in a meaningful way. This means that fishers must fish for a living, requiring them to be out at sea daily or for extended periods of time. Even if they wish to do so, they do not have the time or resources to attend multiple public meetings, engage with voluminous technical information, provide comments, ascertain whether their comments have been addressed in comments and response reports, and thereafter proceed to draft appeals. The result, even if unintended, is that those who have less resources, who are required to be out at sea to make their livelihoods, and/or who are unable to fully understand the different proposals and processes, are not able participate and engage meaningfully. The chilling effect is that they are significantly prejudiced by the onslaught of applications

143. There are many people, particularly those such as small-scale fishing communities and co-operatives who will be impacted by the project, who do not have access to the resources and expertise required to access, consider and comment on the records relating to the project, which are voluminous and technical in nature. The current estimate is

during implementation, should the project be implemented. The SIA specialist has made a reasoned opinion that the project can be approved on the basis of the outcomes of the consultations already undertaken. Communities are diverse and there are community members who are supportive of this type of development, as much as there are community members against the development. Communities were asked to suggest mitigation measures that the specialists should consider, and this influenced some of the recommendations made in the SIA. All perspectives were considered during the EIA process and the social impact analysis.

The SIA report makes detailed recommendations about further engagement with the communities, and other mitigation and management measures. The mitigation and management measures should be considered in its entirety within the context of the report. Efficient engagement with a community involves more than merely setting up a meeting and inviting people. In many communities there is an expectation that outsiders should enter the community via the leadership before a community meeting can take place. TGS needs to determine what the most appropriate way would be to interact, and this may differ between communities, in order to engage with the individuals and communities in a decolonised way. Once this is done, TGS can proceed with engaging with the communities as a whole in an appropriate way. Education is suggested as a mitigation measure to empower community members to make informed decisions where they are in a position to weigh up the pros and cons for themselves, as was requested by community members during the public meetings. The updated conditions (omissions) referred to were included for clarity.

The Appellants assertion that the voices of the communities have not been heard by virtue of the inclusion of conditions requiring that ongoing engagements, education and collaboration is unfounded. The purpose of these measures was to ensure that there were ongoing

that around 136 unitary entities could be defined as 'communities' under the proposed community based rights allocation system. In the Western Cape and Northern Cape in particular, these settlements can seldom be described as 'communities' in the sense of small, spatially defined geographic units with a homogenous social structure and shared norms.[134] This is not recognised nor considered in the BAR or SIA in that the reports appear to limit their analysis by failing to consider the intricate social structures and norms within these "communities" thereby considering these communities as homogenous and disregarding their unique characteristics. 144. We attach hereto a letter from Carmelita Mostert, marked **Annex B5**, which was also separately sent to the Appeals Authority, which clearly sets out opposition to the seismic surveys based on the impact on fisheries, and points out their difficulties associated with having to find hardcopy reports and with having to consider how her community's comments have been considered by the EAP. 145. To ensure access to a reasonable, adequate and fair public participation process, TGS and their appointed EAP should have used reasonably distinctive and appropriate alternative methods to inform and educate affected communities and small-scale fishers of the significant adverse impacts that this project could have on them. Running a public participation process during time period could not achieve meaningful and effective consultation.	interaction, communication and feedback regarding the operational aspects. The EAP has conducted the impact assessment on the basis of the activities proposed by the applicant. Any subsequent authorisation would be restricted to these specifically assessed activities. Should the applicant or other applicants wish to undertake any additional exploration activities which are not addressed in the current Environmental Authorisation (EA) application, there would be a consequent need to apply for the relevant permissions. These would include a formal application for an Exploration or Production Right as well as a new EA. The impacts of such proposed activities would consequently require specific assessment and public consultation prior to approval. It is premature to assess the likely impacts of further invasive exploration activities or production activities as the extent, duration, location, and magnitude applicable to these activities are unknown at this stage. The NEMA EIA Regulations make a clear distinction between the reconnaissance, exploration, and production activities in that these are listed as distinct and separate listed activities. There is provision in law for these activities to be assessed on their merits as and when they are proposed.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
146. The BAR included a Social Impact Assessment (SIA) that noted[159] that communities feel that there were significant gaps in the available data, and that from a social perspective the non-technical or social risks can potentially cause significant impacts. The report highlighted that potential social impacts identified included: • Uncertainty; • Further marginalisation of vulnerable groups; • Concerns about cumulative impacts; • Impact on livelihoods; • Impacts on sense and spirit of place; • Impacts on social license to operate; • Stakeholder fatigue and disillusionment; • Community expectations; and • Social unrest. 147. These impacts are rated in the final BAR as being of high or medium significance prior to mitigation, and as being medium significance post-mitigation.[160] 148. The report further pointed out that seismic reconnaissance projects are controversial in South Africa, and that while for many stakeholders it is an emotional matter, for others the potential of

impacting on their livelihoods is the biggest fear. The report indicates that some stakeholders feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change, while other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. The expert describes this as a 'complex and wicked problem'.[141] 149. The report went on to state that from a social perspective, it is clear that the communities and the majority of local people are opposed to the project, and that because the project does not happen in a social vacuum, the social environment is much wider than the footprint of the project. The report states further that: *If the social risks and potential damage to cultural and indigenous rights are considered the impact on the social fabric of already vulnerable communities may be significant. At this stage communities feel that they cannot make informed decisions.*[142] *(emphasis added)* 150. Curiously, while this TGS SIA is almost identical to the SIA submitted in the Searcher draft BAR (ref. 1518), the TGS version omits the following sentence from the above paragraph:		

[141] Ibid, p8, in a footnote to the TGS final BAR, a 'wicked problem' is indicated as *'a problem that is difficult or impossible to solve because of incomplete, and changing requirements that are often difficult to recognise'*.
[142] Ibid, p8.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
154. The Appellants submitted in their comments on the draft BAR that recommending that the project proceed subject to meaningful consultation being undertaken – and included as a mitigation measure in the environmental authorisation and implemented prior to the commencement of the 'actual survey' – is highly irregular within the context of an environmental impact assessment.[366] There is no legal basis for meaningful consultation to be undertaken after an environmental authorisation is granted, and including such a recommendation as a condition of authorisation undermines the regulatory scheme for prior impact assessment that is subjected to public consultation.		
155. Notwithstanding the above mentioned submissions, the environmental authorisation ("EA") approves the BAR and EMPr, and indicates that it is mandatory for the holder to implement all the recommendations and management measures stipulated in the EMPr throughout all phases of the proposed activities.[367] The EA also stipulates as a specific condition that a community engagement protocol that is based on the San Code of Research Ethics be developed, in consultation with the affected communities and must include a community strategy and grievance mechanism.[368] The EMPr in turn includes as mitigation measures various recommendations under the heading 'Socio-Economic Considerations', all of which are indicated as to be implemented 'Prior to Operation and ongoing'.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
156. The Appellants submit that notwithstanding the public participation processes conducted during the BAR and the SIA processes (which the appellants submitted in paragraphs 115- 121 above, were not adequate or meaningful), it is clear from the SIA that communities and the majority of local people are opposed to the project and that seismic survey companies do not have a 'social license to operate'. The SIA indicates that *'[i]f TGS...wants to proceed with the project, they will need to engage in meaningful conversation with the communities and try to restore relationships. From a community and social risk perspective this is not negotiable'*.[169] The inclusion of mitigation measures in the EMPr (and by reference the EA) fails to adequately take into account the needs and values of the communities (and small scale fishers) who are opposed to the seismic survey.[170] Their voices in opposition to the seismic survey remain unheard in the final BAR and EA. Furthermore, it is submitted that the mitigation measure that TGS should (prior to the operation and on an ongoing basis) *'consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in the future'*[171] cannot be a substitute for meaningful consultation with communities and local people during the EIA process. It is submitted further that such an approach violates the principles of fair administrative decision-making and the right of interested and affected communities to be meaningfully consulted prior to a decision on authorisation being made, and is inconsistent with section 2(4)(f) of NEMA, which stipulates that the participation of all interested and affected parties in environmental governance must be promoted, and all people must have the opportunity to develop the		

[169] TGS SIA, p107.

[170] Section 2(4)(g) of NEMA requires that decisions must take into account the interests, needs and values of all interested and affected parties, and this includes recognising all forms of knowledge, including traditional and ordinary knowledge.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
understanding, skills and capacity necessary for achieving equitable and effective participation, and participation by vulnerable and disadvantaged persons must be ensured. 157. The Appellants also note that the SIA states further that the seismic survey industry should reassess their position and social license to operate as an industry in the South African context and should conduct a strategic environmental assessment of the impact of the industry.[172] Notwithstanding this, the report makes a one-sided assumption that the discovery of commercially exploitable fossil oil or gas resources would be beneficial to the economic development of South Africa: *'Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed'.*[173] The Green Connection and Natural Justice submit that the SIA should have reflected the many negative socio-economic impacts that could or are likely to manifest should commercially exploitable reserves be found and developed through to production and use (including but not limited to the socio-economic costs of climate change[174]). 158. In light of the above, the Appellants submit that the public participation process, including the SIA conducted, did not constitute meaningful consultation with communities and local people (and in particular small-scale fishers), and that the mitigation measures requiring further consultation after the EIA has been conducted and a

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
decision on authorisation made (but prior to the operation and ongoing thereafter) does not cure this flaw in the EIA process. As a consequence, it is submitted that the EA should be overturned on appeal.		
Ground 5. The FBAR does not contain a proper and objective assessment of the negative impacts of the project on people's human rights 159. Small-scale or subsistence fishers in coastal communities heavily rely on local fish populations for their livelihood and cultural practices. If seismic surveys lead to a reduction in fish stocks, it can have negative consequences for these fishers. They may experience reduced catch rates, economic losses, and disruptions to their traditional fishing practices. Furthermore, the cultural and heritage aspects tied to fishing may be undermined if fish populations decline significantly, as it can impact the intergenerational transmission of traditional knowledge and practices. 160. To better understand the correlation and potential impacts, comprehensive scientific studies and assessments are necessary. These studies would need to evaluate the specific local conditions, fish populations, and cultural contexts of the coastal communities in question. 161. Mitigation measures that are proposed within the EMPr, the specialist acoustic studies, socio-economic impact studies and	Section 9.3.3.1 of the BAR in dealing with the cultural heritage impacts, details the following: "The cultural heritage and living heritage related to the communities linked to fisheries and ocean subsistence and further identifying as indigenous communities can potentially be impacted by the proposed project. This impact is indirect and is in the community perceived to be primarily linked to their economic existence as a result in the loss of fishing yield." The Marine Ecological Assessment and the fisheries impact Assessment did not find that there would be a significant impact fishing activities as a result of the proposed seismic survey. As a result, the assumption by the Appellant that there would necessarily be an impact on the cultural practices, is questioned. It should further be noted that the specific local conditions, fish populations, and cultural contexts of the coastal communities in question were considered as part of the BAR as detailed in the Section 8 and 9 and Appendix 3 of the BAR. It is not disputed that the "small-scale or subsistence fishers in coastal communities often have deep cultural and heritage associations with fish and the marine environment. Their practices, traditions, and identity are intertwined with these resources." The impacts identified and the mitigation measures proposed in the Cultural Heritage Assessment and Social Impact Assessment, made it clear that the direct impact on fish populations was considered in detail and highlighted the cultural and heritage significance of fishing. Based on the findings of these studies and as detailed in the BAR, it was the	

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
heritage impact studies such as adjusting survey timing and locations, implementing exclusion zones, and using sound mitigation technologies, can help reduce the potential negative impacts of seismic surveys on marine life. However, when it comes to the cultural and heritage associations of fish and the broader marine environment, proposing the above mentioned mitigation measures which solely focus on reducing direct impacts on fish populations, may fail to address the complex nuances and broader concerns.[175] 162. Small-scale or subsistence fishers in coastal communities often have deep cultural and heritage associations with fish and the marine environment. Their practices, traditions, and identity are intertwined with these resources. Simply mitigating the direct impact on fish populations may not adequately address the cultural and heritage significance of fishing. Preserving cultural practices, traditional knowledge, and the social fabric of coastal communities requires a more holistic approach that recognizes and respects their unique relationships with the marine environment. 163. Small-scale or subsistence fishers in coastal communities understand through their indigenous knowledge of fishing, that the marine ecosystem is capable of sensitivity to outside interferences. As fishers, they have observed that even the slightest interference with the sensitive marine ecosystem will have an impact on every fish in the ocean, and as a result their livelihoods. Plankton, for example, are the most sensitive to any interferences which indirectly have implications for the larger fish species that feed on plankton. Scientific experts have confirmed in their expert assessments that it is likely that the sound blasting in the ocean caused by seismic	opinion of the specialists and the EAP, that the there are no environmental fatal flaws that should prevent the proposed project from proceeding, provided that the recommended mitigation and management measures are implemented. Based on the nature and extent of the proposed project, the local level of disturbance predicted as a result of the reconnaissance activities, the findings of the specialist studies, and the understanding of the significance level of potential environmental impacts, it is the opinion of the EIA project team and the EAP that the significance levels of the majority of identified negative impacts can generally be reduced to an acceptable level by implementing the recommended mitigation measures and the project should be authorised. Consequently, and with due consideration of the mitigation measures recommended by the Cultural Heritage and Social Impact Assessments, it was the opinion of the Applicant and the EAP that the proposed survey will not detrimentally affect cultural practices, traditional knowledge, and the social fabric of coastal communities. Specific mitigation measures that point to the robust consideration of the human rights aspects identified in the BAR include the following: • TGS should develop a community engagement protocol that is based on the San Code of Research Ethics. This should be done in consultation with the affected communities. This should include a communication strategy and grievance mechanism. • TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. • Consult with communities on potential ways in which to make a positive contribution to the communities.	

[175] Page 217-218 of the FBAR

Initials:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
surveys will impact on the behaviour of plankton decreasing the number of plankton in the water.[176] Furthermore experts are of the opinion that seismic testing will have a significant adverse impact on numerous species of marine fauna, including endangered and vulnerable species located in the exploration area, and zooplankton.[177] 164. Mitigation measures that solely focus on addressing direct impacts on fish populations may not be appropriate for effectively addressing the indirect and cumulative effects on the broader ecosystem/ecocentric based cultural and heritage rights associated with fishing. Eco-centric based cultural and heritage rights are rights that can be defined as rights that acknowledge that ecosystems, species, and natural elements have their own rights and should be respected and preserved for their inherent worth, beyond their instrumental value to humans. Within this framework, cultural and heritage rights are understood in relation to the natural environment. Ensuring the protection of eco-centric based cultural and heritage rights involves recognizing and safeguarding the cultural practices, knowledge systems, traditions, and spiritual beliefs of indigenous and local small-scale or traditional fishing communities and other groups that have a close relationship with their surrounding ecosystems. These rights encompass the right to maintain and protect cultural landscapes, sacred sites, traditional	• A representative from TGS should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist with adjusting the relationship between TGS and the traditional communities. Given the socio-political environment, opposition to the project and associated non-technical risks, further meaningful engagement with the leadership and communities are critical from a social perspective. The above mitigation measures demonstrate that there is an onus on the applicant to further engage and develop a deeper understanding of the cultural and social aspects and practices within these communities. The nuances associated with potential disruption of fish behaviour, altered migration patterns, and changes to the ecological dynamics that are crucial to the cultural and heritage aspects tied to fishing, was assessed in detail in the Marine Ecological Assessment and included in Section 9 of the BAR for each of the organism groups. The impacts associated with each of these groups were found to be of LOW significance and fully reversable. It should further be noted that in terms of the fishing, the fisheries assessment was duly cognisant of the relationship between the small scale fishers and the application area, as well as the TEK, which some of the community member referred to during the public meetings, and was duly considered by the specialists. This is evidenced by the following extract from Section 8.5.3.10 of the BAR: *"Small-scale fishermen along the Northern Cape and Western Cape coastlines are*

ecological knowledge, and sustainable resource management practices.[178] 165. The examples of proposed mitigation measures formulated by the EMPr inadequately acknowledge the substantial impact on ecosystem/ecocentric based cultural and heritage rights resulting from the broader indirect and cumulative consequences on fishing populations. 165.1. Implementing exclusion zones to minimize direct impacts on fish populations and sensitive habitats does not sufficiently address the broader ecosystem/ecosystem based cultural and heritage associations of fishing. While exclusion zones can help protect specific areas from immediate harm, they may not consider the holistic connections between fish populations, migration routes, and the cultural practices of coastal communities that extend beyond specific locations. 165.2. Using sound mitigation technologies, such as acoustic deterrent devices, can help reduce the direct impacts of seismic surveys on marine life. However, these measures may not fully address the indirect and cumulative effects on cultural and heritage rights. They primarily focus on	*unlikely to range beyond 20 km from the coastline; thus, inshore of the Reconnaissance Permit area (refer to Figure 83). This assessment is however cognisant of the ongoing issues related to the perceived areas fished and species targeted by SSF off the West Coast of South Africa e.g. that cultural practice of SSF may occur to 55 km offshore. While SSF regulations clearly specify that fishing is required to take place "nearshore" the actual differentiation between SSF and other fishing operations that might include SSF, such as the commercial "traditional linefish" and "pole and line" and the extent to which these commercial fisheries might include SSF, remains unclear. As such the offshore extent to which SSF may operate requires a precautionary approach in this assessment and consideration that the possibility exists (albeit a remote possibility that cannot be verified through the information made available on these fisheries), that SSF may have occurred historically and potentially in the future further offshore than suggested by the information made available for this assessment i.e. there is a remote possibility that some SSF may have targeted certain species (of which tuna and snoek are the main candidate species) further offshore than 20 km. The distance fished offshore by SSF and the associated risks determined in this assessment further necessarily considers practical aspects, notably that bottom fishing is impractical in waters deeper than 100 m and as such any bottom fishing, whether SSF or commercial, is highly unlikely beyond a precautionary depth being the 100 m depth contour. Further, in regard to migratory species, such as longfin tuna and snoek, economic and regulatory aspects relating to distances fished offshore is pertinent (i.e. such as the requirements of the South African Maritime Safety Authority [SAMSA]) in particular that most SSF are not likely to be "B" class certified (i.e. can operate up to 40 nm offshore and*

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
reducing noise levels and immediate physical harm, but do not consider the potential disruption of fish behavior, altered migration patterns, or changes to the ecological dynamics that are crucial to the cultural and heritage aspects tied to fishing. 165.3. Temporal restrictions, such as conducting seismic surveys during specific seasons or avoiding critical reproductive periods, may help reduce direct impacts on fish populations. However, these restrictions may not fully address the indirect and cumulative effects on the cultural and heritage rights associated with fishing. Cultural practices and traditional knowledge often extend beyond specific seasons and reproductive periods, and the long-term sustainability of fishing traditions and associated rights may depend on the availability of fish populations throughout the year. 165.4. Implementing measures specifically focused on protecting certain fish species or habitats may not comprehensively address the broader cultural and heritage rights tied to fishing. While protecting specific species or habitats is important for biodiversity conservation, cultural and heritage associations with fishing often encompass a diverse range of species, ecosystems, and traditional practices that go beyond the conservation of individual components.	*are longer than 9 m) are likely limited to "C" class being mainly vessels of <9 m21 permitted to only operate < 15 nm offshore."* It should be noted that the ecosystem level impact and interrelationships are described in section 4.3.8 of the Marine Ecological Assessment. The recommendation of the SIA is that, should the project be approved a representative from TGS must consult with leadership of the community to determine how the communities should be consulted with in future – that is, what is the way the community members prefer to be consulted with for provision of commencement notification and/or daily updates to advise on survey schedules, communication in respect of the proposed research outcomes, etc. The recommendation to include further consultation as part of the conditions of authorisation intends to ensure that the consultation process goes further than just the EIA process, but is continued throughout the entire process, regardless of the outcome. This will assist communities and people on the ground to make informed decisions about technical matters. The intention of the recommendation is not for this condition to be suspensive or determinant on the ultimate decision but rather to function as an additional management/ mitigation measure to be implemented post approval to reduce the significance of the identified impacts and further enhance the community engagements during implementation, should the project be implemented. The SIA specialist has made a reasoned opinion that the project can be approved on the basis of the outcomes of the consultations already undertaken. Communities are diverse and there are community members who are supportive of this type of development, as much as there are community members against the development. Communities were asked to suggest mitigation measures that the specialists should consider, and this influenced some of the recommendations made in	

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
166. To effectively address the indirect and cumulative effects on ecosystem/ecocentric based cultural and heritage rights associated with fishing, mitigation measures should take a more holistic and inclusive approach that consider and incorporate the following aspects: 166.1. Incorporating the perspectives and insights of coastal communities into decision-making processes, ensuring their meaningful participation in the development and implementation of mitigation measures. 166.2. Recognizing and preserving cultural and heritage practices by considering the broader socio-cultural contexts, intergenerational knowledge transfer, and the long-term sustainability of traditional fishing practices. 166.3. Integrating traditional ecological knowledge with scientific research to inform mitigation strategies and ensure that they address the interconnectedness of fish populations, ecosystems, and cultural and heritage rights. 167. While the mitigation measures may focus on reducing direct impacts, there can be indirect and cumulative effects that are not fully addressed. Seismic surveys, even with mitigation, can still cause disturbances, alter fish behavior, or disrupt migration patterns, which may have cascading effects on the broader ecosystem. 168. Given the ecosystem impacts, seismic testing will likely result in a trophic cascade affecting all levels of the food chain and therefore indirectly impacting on small-scale fishing communities. The Fisheries Specialist failed to assess the potential impact of the seismic surveys on zooplankton in and around the survey area, as well as the knock-on effects that zooplankton die-off would have on the fish species on	the SIA. All perspectives were considered during the EIA process and the social impact analysis.	

Initials:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
which small-scale and subsistence fishers rely for their sustenance and livelihood.[179] These indirect knock on and cascading effects on the dynamic and interconnected ecosystem could potentially affect not only food security for local small-scale fishing communities, but could also impact on the ecosystem/ecocentric based cultural and heritage rights associated with fishing. Counter to the requirements of NEMA and the NEM:ICMA, the BAR and the competent authority's decision does not consider impacts from an ecosystem perspective, and as a consequence, the "downstream" impacts have not been adequately assessed and presented to the DG. 169. Additionally, the cumulative impacts of multiple surveys or other anthropogenic activities in the area need to be weighed together. These indirect and cumulative impacts can have implications for cultural and heritage associations, as they may disrupt traditional practices and the functioning balance of the marine ecosystem. 170. Given the absence of a socio-economic impact assessment which adopts an ecocentric and ecosystem approach to the assessment of impacts, and which should have evaluated the cascading impacts on food webs, and how this will impact on the right to access of sufficient food as well as the associated connections of heritage and cultural rights to the practices of fishing, relevant information was not placed before the decision-maker. In the absence of that information, a precautionary approach should have been adopted. This omission is material – the right to food and culture and heritage are constitutionally enshrined – and consequently the authorisation should not have been granted.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
171. Small-scale fishers often possess traditional ecological knowledge ("TEK"), which includes their understanding of fish behavior, spawning grounds, and the dynamics of the marine environment. This knowledge is often based on observations passed down through generations and is deeply connected to their cultural heritage. Proposing mitigation measures without considering and incorporating TEK may overlook valuable insights and alternative approaches that could better protect both the fish populations and the ecosystem/ecocentric based cultural and heritage rights of coastal fishing communities. 172. Given the above, it is submitted that the proposed and authorised mitigation measures are inadequate. The mitigation measures set out in the EMPr are designed to re-assess impacts post-project.[180] This is flawed for a number of reasons, including: 172.1. The proposed measures are aimed at providing "resources and support for communities to develop and undertake safeguarding measures or plans to enhance the mitigation capacity of their intangible cultural heritage by fostering dialogue, mutual understanding and reconciliation between and within communities" which in no way holds TGS accountable for any impacts caused by the 3D seismic surveys activities. 172.2. The proposed mitigation measures fail to comprehend and mitigate any of the economic or		

[180] Page 30 of the EMPr

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
other harms to livelihoods, and cultural and heritage practices and identity. 173. The pre-mitigation significance given to the socio economic and cultural and heritage impacts are rated as Medium, and then Low post mitigation. If mitigation does not actually change the impacts, then it is implausible that the rating can change significantly as well. There is no rational connection between the results of the arbitrary, and somewhat absurd, mitigation measures and any change in significance with regards to the impacts caused by the reconnaissance activities on coastal communities. 174. The Social Impact Assessment (SIA) and Heritage Impact Assessment urges the need for dialogue and engagement with communities prior to the commencement of these activities as the Expert confirms that the oil and gas companies do not have a social license to continue currently.[181] However, there is evidence of any further dialogue with these communities with regards to addressing issues specifically relating to the indirect and cumulative effects on cultural and heritage rights associated with fishing. 175. Therefore, engaging and involving coastal communities in the decision-making process is crucial. Meaningful consultation and participation allow communities to express their concerns, share their knowledge, and contribute to the development of effective mitigation measures. Failure to include the perspectives and needs of these communities can result in measures that do not adequately		

[181] Page 109-110 of the SIA, and page 56, 58 of HIA.

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
address their cultural and heritage associations and may lead to further marginalization. 176. Despite the apparent expert knowledge and the level of understanding expressed in the report recommendations regarding the potential effects of the seismic survey proceeding on the communities' identity, sense of place, and spiritual, cultural, and indigenous rights, and that decisions must consider the interests, needs, and values (our emphasis) of all interested and affected parties, including acknowledging all forms of knowledge, including traditional and ordinary knowledge,[182] it is clear that necessary deep conversations with coastal communities were not conducted. Consequently, insufficient information was placed before the decision-maker, and he/she neglected to afford sufficient weight to the indigenous and cultural rights of coastal communities.		
<u>Ground 6: *Failure to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008*</u> 177. Section 63(1) of NEM:ICMA requires a competent authority to take account of specific factors when deciding whether or not to grant an environmental authorisation under NEMA for "coastal activities". By virtue of this section, the decision maker ought to have appreciated that in deciding whether to grant an environmental authorisation or not, he or she was required to consider additional	Section 4 of the BAR does list the Integrated Coastal Management Act (ICMA) and the Marine Living Resources Act. The decision-making authority was required to consider the principles and obligations of the ICMA in the decision making process. The marine fauna study assesses the potential impacts of the survey on the marine environment. The proposed survey activities to be undertaken by TGS are expected to result in impacts on marine invertebrate fauna in the Orange Basin, ranging from negligible to very low significance. Only in the case of potential impacts to turtles and marine mammals are impacts of low significance expected. If all

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
factors specified in section 63 of NEM:ICMA[183] and whether or not the proposed project "would be contrary to the interests of the whole community". This required an eco-centric consideration of the impacts of the proposed project in an area that must be afforded a particularly high standard of protection given the natural functioning of the dynamic coastal processes. 178. Section 12 and 21 set out the State's obligation in relation to the management of the coastal zone, which must be taken into account in taking a decision in respect of this zone. 179. The Director-General's decision makes no mention of section 63 of NEM:ICMA, and the ESIA contains no evidence that the factors set out in section 63 was considered or assessed. Whilst the BARidentifies that section 63 of NEM:ICMA is applicable, it does not assess each of the factors set out in section 63. 180. Read together, this means that there was no factual investigation as required by section 63 of the NEM:ICMA, including a determination of whether the coastal public property and the coastal protection zone would be impacted, and if so, to what extent the proposed activity is consistent with the goal of establishing or protecting those areas.[184]The management plans that are relevant in these areas, like the Coastal Management Programme for the	environmental guidelines, and appropriate mitigation measures recommended in this report are implemented, there is no reason why the proposed seismic survey programme should not proceed. With respect to the management and conservation of protected areas noted in the ICMA and MLRA, this is discussed in Section 8.6 of the BA Report. In terms of protected areas, Child's Bank and Tripp Seamount lie outside of the proposed 3D survey area, and any demersal species associated with these important fishing banks would receive the seismic noise within the far field range, and outside of distances at which physiological injury or avoidance would be expected. Despite the current lack of knowledge of the community structure and endemicity of South African macroinfauna off the edge of the continental shelf, the marine component of the 2018 National Biodiversity Assessment, rated the South Atlantic bathyal and abyssal unconsolidated habitat types that characterise depths beyond 500 m, as being of 'Least concern', with only those communities occurring along the shelf edge (-500 m) being considered 'Vulnerable'. This primarily reflects the great extent of these habitats in the EEZ. Numerous sanctuaries, marine protected area (MPA) exist offshore and along the coastline of the Western Cape, although none of them overlap with the Reconnaissance Permit Area. Seismic surveying is not only used for petroleum and natural gas exploration and development. In addition, the National Coastal and Marine Spatial Biodiversity Plan for the coast and ocean around the South African mainland states that petroleum production may be possible in CBAs using lateral drilling or other techniques that do not result in biodiversity impacts. According	

[183] S 63(1)(c), s 63(1)(h)(ii), s 63(1)(h)(iv) and s 63(1)(i) of NEM:ICMA.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
Western Cape Province,[185] have also not been taken into consideration. 181. The BAR does not, at any point, consider the interests of the affected human and non-human communities in any collective way. Consequently, the interests of the whole community[186] have not been presented to the decision-maker in the BAR, and without evidence of specific consideration of these interests in the Reasons for the Decision, the decision-maker has not evaluated these interests in their decision to grant environmental authorisation. 182. As set out elsewhere in this appeal, the impacts associated with seismic surveys could have significant impacts on marine life and coastal communities. Oceans play a critical role in regulating the climate and mitigating global warming by absorbing carbon dioxide. Seismic surveys pose a significant threat to functioning marine ecosystems, to living organisms in South Africa's coastal waters, and	to the plan if significant petroleum resources are identified in these areas the selection of the site as a CBA could be re-evaluated, although this would require alternative CBAs to be identified to meet biodiversity targets. No MPAs are located within the proposed survey area. Zero no-go areas within the proposed survey area have been identified in any of the specialist studies conducted. It should further be noted that the interests of the whole community (from and intra- and inter-generational perspective, as well as having regard to potential impacts on living organisms in South Africa's coastal waters) was indeed assessed in the assessing of the marine ecology, the impact on the fishing industry, the detailed social and cultural heritage assessments, and the public consultation undertaken. With regards to the requirements of Section 63 of the NEM:ICMA, the Competent Authority thus had sufficient information at their disposal in order to reach an informed decision regarding the proposed activity.	

[185] Western Cape Coastal Management Programme: 2016 available at https://cer.org.za/wp-content/uploads/2009/12/Western-Cape.pdf
Draft Western Cape Coastal management Programme 2022 – 2027 available at https://www.westerncape.gov.za/eadp/files/atoms/files/DRAFT%20Western%20Cape%20Provincial%20Coastal%20Management%20Programme%202022-2027.pdf.

[186] In terms of the National Environmental Management: Integrated Coastal Management Act 24 of 2008 (NEM:ICMA), the 'interests of the whole community' is defined as meaning the collective interests of the community determined by:

(a) prioritising the collective interests in coastal public property of all persons living in the Republic over the interests of a particular group or sector of society;

(b) adopting a long-term perspective that takes into account the interests of future generations in inheriting coastal public property and a coastal environment characterised by healthy and productive ecosystems and economic activities that are ecologically and socially sustainable; and

taking into account the interests of other living organisms that are dependent on the coastal environment.

Initial/s:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
to communities that depend upon the oceans for their livelihoods. Small-scale fishers and fishing-dependent communities are particularly vulnerable to the negative impacts on fish stocks upon which they depend for their livelihoods. 183. The Appellants submit that it is not in the interests of the whole community (from and intra- and inter-generational perspective, as well as having regard to potential impacts on living organisms in South Africa's coastal waters] to expose our oceans and coasts to the increased risks associated with seismic surveys, or associated with further intended exploratory drilling and/or production activities.		
<u>Ground 7</u> *Failure to provide adequate reasons for the decision* 184. The reasons for the DG's decision, as described in Appendix 1 of the Environmental Authorisation ("the EA"), sets out that the following were 'key findings' that resulted in the decision to approve TGS's application for environmental authorisation: 185. The decision concludes as follows: *In view of the above, and having taken into consideration environmental management principles as set out in section 2 of NEMA, this Department is satisfied that the proposed activity will not be in conflict with the objectives of Integrated Environmental Management set out in Chapter 5*	It is the opinion of the Applicant that the Competent Authority thus had sufficient information at their disposal in order to reach an informed decision regarding the proposed activity.	

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
of [NEMA] and will not result to any detrimental risks to the environment and public. The environmental authorisation is accordingly granted. 185. These reasons, and the conclusion arising from these reasons are generic and unsubstantiated. The reasons are almost verbatim the same reasons provided by the DG in other oil and gas related applications, such as those contained in the Environmental Authorisations for Searcher Geodata UK Limited and TotalEnergies EP South Africa Block 567 (Pty) Ltd . The EA itself further fails to deal substantively with any of the main issues raised by the Appellants and other I&APs. 187. On the reasons provided, it is impossible to conclude that the DG took all relevant considerations into account, including the submissions made by the Appellants and other interested and affected parties. To the contrary, it appears that the DG failed to consider all relevant information, for the reasons set out elsewhere in this appeal		
Ground 8. Decision to grant authorisation contravenes NEMA Principles, the Constitution and PAJA 190. Section 33 of the Constitution recognises that everyone has the right to administrative action that is lawful, reasonable and procedurally fair. PAJA seeks to give effect to this right.	It is the opinion of the Applicant that the Competent Authority thus had sufficient information at their disposal in order to reach an informed decision regarding the proposed activity.	

Initials

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
191.From what is set out above, it is clear that the decision to grant authorisation to TGS runs contrary to at least the following NEMA principles: 191.1. Decision-makers must apply the precautionary principle when there is uncertainty or lack of scientific consensus regarding potential environmental harm. This principle requires taking preventive action to avoid serious or irreversible environmental damage, even in the absence of full scientific certainty. 191.2. Decision-making should promote equity and fairness in the distribution of environmental benefits and burdens. This principle recognizes the rights of all individuals, particularly disadvantaged and vulnerable groups, to a healthy environment and seeks to avoid disproportionately negative impacts on these groups. 191.3. Decision-makers must protect and conserve ecosystems, biodiversity, and ecological processes. This principle recognizes the intrinsic value of ecosystems and the critical role they play in supporting life and maintaining ecological balance. 192.It is further submitted that 192.1. Irrelevant considerations were taken into account or relevant considerations were not considered;		

Initial/s

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
192.2. the action itself contravenes a law or is not authorised by an empowering provision; 192.3. the action itself is not rationally connected to the information before the administrator; and 192.4. the exercise of the power or the performance of the function authorised by the empowering provision, in pursuance of which administrative action was purportedly taken, is so unreasonable that no reasonable person could have so exercised the power or performed the function. 193.The decision is consequently reviewable under section 6(2) of PAJA. CONCLUSION 194.The Appellants have sent out in this appeal a number of grounds on which the decision to grant environmental authorisation to TGS was fatally flawed. The decision to authorise the project is consequently unlawful, in that it failed to comply with, inter alia, the Constitution and NEMA.

pressures, and the inability of the prescribed mitigation measures preventing harm to individuals/populations. Furthermore, recent literature provides credible concern about ecosystem/food-chain impacts of seismic surveys, that may in turn have impact on fisheries, the severity and localisation of which will depend on coincidences with spawning and juvenile recruitment events. It is strongly recommended that further studies on these impacts, in the South African context, are carried out *in situ* before proceeding with further seismic surveys of this nature.

Summary of Findings

- Based on peer-reviewed scientific literature, it is clear that physical damage to marine animals, including soft tissue trauma damage, embolisms, damage to organs used in balance and orientation, concussions, haemorrhaging, decompression sickness and both temporary and permanent threshold shifts to hearing ability have been directly linked to the kind and level of sound emitted during this nature of seismic surveys.
- There is plausible evidence to suggest that seismic survey activity is likely to affect the conservation status and recovery of populations of vulnerable and threatened species including (IUCN Red list species such as humpback and southern right whales), because sound and the ability to hear and interpret sound is critical for many species to reproduce (both vocalisations on breeding grounds and communications across large distances for mate detection). Therefore, it must be assumed that interference in sound perception or utilisation for communication (temporarily or permanently) has the potential to impact a species at the population level.
- Some species have been shown and documented to display physiological stress responses and behavioural changes to seismic activities, such as moving away rapidly, diving or remaining still. These responses are likely to increase their energy consumption

and energy costs, reduce their time to forage, and/or affect their vulnerability to predation, thus having negative impacts on the survival of individuals (especially young or compromised animals) as well as the overall population growth and survival of a species (especially for threatened species that are already at risk of extinction).

- The impacts of seismic activities are most well studied for marine mammals, and evidence suggests that there are distinct avoidance responses such as leaving the area or ceasing to undertake everyday activities such as feeding in preferred areas. This is likely to negatively impact the "fitness" of an affected animal.
- There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.
- The only existing field study in South Africa (that we have been able to find) on the impacts of seismic activities in our waters is illuminating in this regard. It presents clear evidence that the endangered, endemic African penguin avoided preferred feeding sites when a seismic survey was active nearby. This is particularly of concern for a species which has had a 70% decrease in numbers over the past decade, is stressed by prey depletion creating a greater demand for them to forage further afield, and for which the prospect of extinction is significant.
- The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a

EXECUTIVE BOARD MEMBERS: Ms A Weakley (Chairman), Mrs H Hewitson-King (Vice Chair), Mr P Bodle, Mrs P Ellis, Mr S Phakathi, Mr A Patel, Ms B Kuzwayo, Mr M Below

EXECUTIVE DIRECTORS: Dr I Hanic, Ms S Singh

vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.

- Recent research (2017) has shown significant mortality in zooplankton up to 1.2 km from a seismic survey array. Zooplankton forms the base of many important food webs in the marine environment. Depletion of zooplankton could thus have an impact on food for their predators (such as fish) as well as impact fish eggs and larvae (Ichthyoplankton) with potential local impacts on species important in fisheries. This damage to zooplankton over 1km away from the survey array raises concern that a 500m buffer for other animals that are unable to move away from the sound, is far too small to ensure that damage is not inflicted (even if they were able to evade it).
- The impact on fish assemblages is difficult to interpret, due to multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. A global review of the effect of seismic activities on fish and invertebrates acknowledged the limits of the current research due to experimental designs used or due to the focus on single species during investigations. A key concern is a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys that have been previously identified may be reflective of underestimation or overestimation and would depend on the type of interaction (synergistic, additive, or antagonistic).
- In South Africa, since October 2021, thousands of dead and/or dying Cape fur seals (*Arctocephalus pusillus pusillus*), have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. It is of concern that although the cape fur seal population within South Africa is relatively healthy, they too are

under pressure from various anthropogenic pressures. Additional stress from seismic activity at this time is inadvisable.

- While "Soft starts" mitigation for seismic impacts are likely to reduce the impact for highly mobile large animals, this is unlikely to be adequate for the many species that are prevalent in the area over the austral summer months and are unable to avoid the array or leave the area due to their lower mobility, such as smaller turtles, penguins, invertebrates, some fish species and zooplankton.
- The finding of observer efficiency (from a scientific monitoring study conducted during the 2018/19 and 2019/2020 seasons on the humpback whales on the east coast) suggests that even with trained observers up to 44% of humpback whales in an area went undetected. This casts doubt on the effectiveness and success of Marine Mammal Observer (MMO) sightings of the largest species (humpbacks) as a mitigation measure, indicating that it is most likely that whales go undetected. Furthermore, the detection rate for smaller species, such as dolphins, seals, turtles and flightless birds (penguins), would be expected to be much lower, obviating the effectiveness of visual observations to prevent harm to these species.
- Also of concern, is that the efficacy of Marine Mammal Observers (MMO) is likely to be low due to the nature of the offshore marine environment in the survey area (frequent high swells and winds affecting surface visibility), putting species who are missed by MMO's and PAM operators at extreme risk, particularly at night or during adverse weather conditions.
- Furthermore, the reliance on Observers to do visual sightings to supplement the PAM monitoring during the day, as a mandated mitigation measure, necessitates that we question the acceptability of continuing with survey activities at night. If the visual observations are useful (perhaps sighting large animals around 65% of the time) in

addition to PAM, then relying on PAM alone at night cannot be an effective mitigation measure. It is our opinion that surveys should not occur between sunset and sunrise each day if a genuine attempt of maximum avoidance of cetaceans is the objective of this mitigation measure.

- It is of our opinion that the proposed seismic survey activities are highly likely to both disturb and have an adverse effect on Marine Protected Areas (MPA), Critical Biodiversity Areas (CBA) and Ecologically or Biologically Significant Areas (EBSAs), and their associated fauna, situated adjacent to, within and surrounded by the reconnaissance permit area. The reconnaissance permit area occurs adjacent to six Marine Protected Areas and surrounds a seventh (Benguela Muds MPA). In the EMP, there is no reference or provision made regarding buffer areas around these protected areas or for areas identified with biological importance and significance. Therefore, it is assumed that the vessel can actively work within 1 km of the MPA boundaries, while ignoring EBSA's and CBA's altogether, thus giving no consideration to the biological importance of these areas or the likely impact at such close range. Although 2D surveys are proposed for these adjacent areas, the cumulative zone of impact for Permanent Threshold Shift (PTS) and Temporary Threshold Shift (TTS) for physiological injury is between 500 - 5000m respectively.

Global context – Impacts of seismic surveys on marine wildlife

Despite seismic surveys having been undertaken for decades in South African waters, together with the knowledge that some impact to marine fauna does indeed occur[1], there remains very little scientific research on the effects of seismic surveys, and in addition there

[1] https://jnnc.gov.uk/our-work/marine-mammals-and-noise-mitigation: "to reduce the risk of deliberate injury to marine mammals".

EXECUTIVE BOARD MEMBERS: Mr A Nicholls (Chairman), Mrs N Newton-King (Vice Chair), Mr P Beck, Mrs P Ellis, Mr E Phakathi, Mr A Paul, Ms B Rajaraya, Mr M Balcon

are no legislated guidelines for seismic surveys in South African waters (Purdon 2018). Globally, seismic surveys' environmental impacts and consequences are slightly better documented, although not uniform in results or widely accepted within all sectors. The primary mitigation measures for seismic surveys in South Africa include soft-starts, which is a gradual and systematic increase in power of the airgun array undertaken to warn and drive mobile marine species, such as cetaceans (whales and dolphins), seals, flightless birds and turtles away from the sound source before the full-power airgun blasts begin, thus attempting to minimise the negative effects of the airgun blasting activity. Various studies contest this assumption (McCauley et al. 2000; Weilgart 2013; Dunlop et al. 2016) and have revealed a growing concern for animals that are unable to avoid or out-swim the airgun arrays.

Animals use sound critical to their life cycles (Jasny et al. 2005) in three ways, by actively producing sound (Tyack 1981), by listening to sounds emitted by other living organisms (Clark et al. 2009; Van Opzeeland 2010), and taking cues from physical or non-living factors producing sounds, contributing to the ambient background noise, such as wind, waves, swell, bubbles, currents, turbulence, earthquakes, rainfall, ice cracking or breaking (Hildebrand 2005). Many marine animals produce sound for communication, reproduction, aggression, defence mechanisms, antagonistic interactions, courtship, group coordination, orientation, navigation, and prey identification (Hildebrand 2005). They rely on producing a sound that is heard while hearing a sound and interpreting the sound for their survival.

Various physical responses to acoustic disturbance have been documented, with physical responses including soft tissue damage (Balcom and Claridge 2001), embolisms (Dolman and Simmonds 2005), damage to organs used in balance (André et al. 2011), concussions in penguins (Cooper 1982), haemorrhaging (Evans et al. 2001) and decompression sickness

(Fernández et al. 2005). Hearing impairment in the form of Temporary Threshold Shift (TTS) or Permanent Threshold Shift (PTS) has also been reported (Hildebrand 2005). Threshold shift refers to an increase in the minimum sound level required for an animal to hear a sound. A TTS is followed by successful recovery to normal hearing thresholds after a given period of time in the absence of that sound, while PTS is when the sensory hair cells in the inner ear are permanently damaged and lost making recovery impossible (Weilgart 2013).

Stress caused by disturbance is associated with a change in body chemistry (Jasny et al. 2005) and can be equally disruptive as physical damage. Stress has implications on sexual maturation, inhibits growth, reproduction and general survival ability (Pickering 1992; McCormick 1999; Consten et al. 2001). Perceptual effects can occur when there is an interference of sounds of interest to a specific animal but are being drowned out or masked by anthropogenic noise. The impact of this in the long term could have implications on breeding populations, thus on reproduction within a population (Erbe 2001). Many animals may have the ability to counteract this and make minor changes to their vocalisations and behaviour; however, these modifications may come at a cost in terms of energy expenditure (Tyack 2008) and are likely to reduce breeding productivity of the population. This is of particular concern for species that are threatened.

Behavioural responses to noise are dependent on various factors, such as age, sex, presence of offspring, location and an individual animals' previous encounter with a specific sound or noise. Behavioural responses may include modification of vocal behaviour, displacement from important habitats, and other subtle responses, including increased breathing rates, change in dive duration, time spent at the surface, rapid or erratic movements (Bowles et al. 1994; Lesage et al. 1999; Williams et al. 2002; Hastie et al. 2003; Ng and Leung 2003; Aguilar de

Soto et al. 2006). These all with potentially high energetic costs (Williams et al. 2006; Koper and Plön 2012).

Most scientific research on the impacts of seismic surveys has been conducted on cetaceans, and as a result, most mitigation measures are to protect these animals. In South Africa, this is no different. However, it is becoming more and more evident that mitigation measures are not adequate (Weilgart 2013). In the Gulf of Mexico, it was recorded that ~250 male fin whales appeared to stop singing for several weeks to months during a seismic survey. These animals resumed singing within hours or days after the survey ended (IWC 2007). The assumption is that male fin whales use vocalisations for reproduction by finding and attracting mates (Croll et al. 2002); it can only be assumed that such an effect would be biologically significant (Weilgart 2013). In addition to this, a blue whale ceased calling in the presence of a seismic survey at 10 km away (Macdonald et al. 1995). Conversely, a different group of blue whales appeared to have the opposite reaction. They changed their vocalisations (De Lorio et al. 2010) by calling consistently more on days when the seismic surveys were actively ongoing, suggesting that seismic survey noise interfered with important signals used in their social interactions and feeding (De Lorio et al. 2010).

Other reactions to seismic airguns can be subtle or hard to detect (Weilgart 2013) and it has been found that Sperm whales in the Gulf of Mexico did not appear to avoid a seismic airgun survey area but reduced their swimming effort and their tendency to reduce foraging effort (Miller et al. 2009). It has also been documented that as a result of changes in behaviour, the result could be lower reproductive rates and have negative consequences for the population (Miller et al. 2009). In comparison, bowhead whales showed no avoidance or change in vocalisations in the area of seismic surveys; however, their dive duration was shorter

(Richardson et al. 1986). In Brazil, a reduction in cetacean species diversity during 2000 and 2001 was noted with the increased occurrence of seismic surveys in the area being implicated in the possible cause of these animals vacating the area (Parente et al. 2007). In other areas, marine mammals have been recorded to avoid seismic noise by leaving an area (Castellote et al. 2012; Weir 2008; Stone and Tasker 2006). The long-term impacts of various changes in behaviour is largely unknown but potentially impact their ability to feed and/or reproduce as in some species, these life-history stages are site or habitat-specific.

South Africa's south and west coasts are hosts to eight species of beaked whales (Ziphiidae) (Best 2007), including a new species described in 2021 (*Mesoplodon eueu*; Carroll et al. 2021), which are globally recognised as being sensitive to anthropogenic noise, and having raised conservation concerns. New et al. (2013) found that adult female beaked whales could survive but not reproduce in times or areas of lower habitat quality. They may extend the duration of lactation in mediocre conditions to increase their chance of survival, while still reproducing. New et al. (2013) found that some beaked whale species require high-quality habitat to meet their requirements for reproduction and survival. They suggested that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.

McEwen and Wingfield (2003) suggested that all organisms must gather energy for growth and reproduction throughout their life cycle and that organisms must retain reserves for predictable changes such as seasons, and challenges that are less predictable such as disturbance, predation pressure, or social conflict. Often colloquially, this is referred to as the "fitness" of the animal. The accumulated cost in the balance between energy intake and demand is called the 'allostatic load', of physiological and behavioural mechanisms that enable

EXECUTIVE BOARD MEMBERS: Mr A Nepomuk (Chairman), Mrs H Newton-King (Vice Chair), Mr P Bode, Mrs P Ellis, Mr E Phahuthi, Mr A Patel, Ms B Mazwayo, Mr N Bekoi
PATRONS: Dr G Hughes, Dr M Bucheliet, Mr P Goss
CEO: Dr R Klopper
EXECUTIVE DIRECTORS: Dr J Harris, Mr S Singh

allostasis or adaptation to these changes. McEwen and Wingfield (2003) use the word "allostasis" to signify mechanisms that allow an organism to regain equilibrium while dealing with external challenges; if energy demand is more than intake, then animals may activate a survival mode that may increase energy available, reduce energy demand, or both, to regain its energy balance. Implications on individuals and populations of this energy imbalance are unknown.

Several studies have reported negative impacts of acoustic signals from airguns on zooplankton (small, aquatic microorganisms living in the water column, including crustaceans, larvae, juvenile fish, juvenile invertebrates, eggs etc.) from more than 10m away (Kostyuchenko 1972; Kosheleva 1992; Parry *et al.* 2002) with some laboratory experiments on lobster larvae showing no impact at all (Day *et al.* 2016). However, Christian *et al.* (2003), showed retardation in some individuals in the development of snow crab eggs after being exposed to certain sound levels.

The effects of seismic noise on zooplankton were brought under the spotlight when McCauley *et al.* (2017) presented evidence from an *in-situ* study that suggested that seismic surveys cause significant mortality to zooplankton populations. Zooplankton, unlike vertebrates, do not have hearing structures (although they can sense pressure change) and their bodies are generally the same density as the surrounding water, so sudden pressure changes associated with seismic activities were presumed not to cause physical damage (Parry and Gason 2006). McCauley *et al.* (2017) disputed this and has shown zooplankton mortality at distances of up to 1.2km from the sound source.

Similarly, inconsistent findings occur with fish assemblages. The impacts on fish assemblages are difficult to interpret, because of multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. We acknowledge the validity of the results presented by Meekan et al. (2021) which highlights that exposure to an experimental seismic source did not have an impact on the assemblage of tropical demersal fishes found along the northwest shelf of Western Australia. However, it must be noted that the findings have been stated to be applicable only to other habitats with similar physical environments, in particular similar water depths (50 – 70 m). The proposed reconnaissance permit area on the south and west coasts of South Africa differs significantly from those reported in the Meekan et al. (2021) research, thus highlighting the need for South African-specific and local research to be undertaken.

A global review of the effect of seismic activities on fish and invertebrates by Carroll et al. (2017) acknowledged the limits of the available research due to experimental design, or to the focus on single species which prevents extrapolation to other regions, other seismic surveys, species, or biological responses. In addition, they highlighted a serious concern, that there was a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys which had previously been identified may be reflective of under-estimation or over-estimation and would depend on the type of interaction (i.e. synergistic, additive, or antagonistic).

Furthermore, the indirect effects of seismic activity on cetaceans is a concern. It is well known that the productivity and health of the oceans are under-pinned by marine plankton (Raymont 1983; Alcaraz & Calbet 2009). While forming the basis of the food webs, plankton has been implicated in links to climate change via their role in iron fertilisation and carbon sequestration

through whales foraging on krill and subsequent defecation (Smetacek and Nicol 2005; Smetacek 2006; Nicol et al. 2010). In 2010, Pershing et al. suggested that over-fishing of large fish and commercial whaling had compromised the ocean's ability to store and sequester carbon, thus contributing to climate change. They indicated that populations of large baleen whales now store 9.1×106 tonnes less carbon than before commercial whaling and that protecting whales (and other large over-exploited species), would be a form of a carbon management scheme. The cascading and knock-on effects of seismic survey impacts between the upper (cetaceans) and lower reaches (plankton) of the food web, as each are being impacted are unknown. McCauley et al. (2017) noted that the ramifications of compromised larval recruitment could be massive for higher predators and for ocean health as a whole. While traditional feeding grounds for humpback whales are in Antarctic waters, Dey et al. (2021) has recently recorded regular feeding frenzies off the west coast in recent years (see super pods below).

South African Context

It is of concern that there are a number of 'unknowns' and 'warning bells' in terms of cetacean populations on the south and west coasts. Despite various species being recorded frequently on the coasts, the location of breeding grounds of Sei (*Balaenoptera borealis*) and Fin whales (*Balaenoptera physalus*) are unknown, the seasonality of pygmy (*Kogia breviceps*) and dwarf (*Kogia sima*) sperm whales are unknown and the abundance and occurrence of the offshore common dolphin (*Delphinus delphis*) is also unknown, highlighting that encounters with these animals cannot be predicted and the generic mitigation measures may be insufficient. Further to this, it is noted in the EMP submitted by Searcher that the two very well-studied and frequently observed species on the south and west coasts, the humpback and southern right whales, ***are expected to be regularly encountered and have a year-round occurrence***

EXECUTIVE BOARD MEMBERS: Mr A Norris (Chairman), Mrs H Newton-King (Vice Chair), Mr P Bodi, Mrs P Ellis, Mr E Phakathi, Mr A Paul, Ms B Rutherford, Mr N Bellew

across the entire reconnaissance permit area. The period of humpback whales in this area is between July and February, with frequent feeding encounters during the months between December to February. Barendse et al. (2010), Best & Allison (2010), and Elwen et al. (2014) highlighted that there is no existing evidence of a clear 'corridor' of migration and humpback whales appear to be spread out widely across the shelf and into deeper pelagic waters, especially during the southward migration, in the Benguela ecosystem.

Further to this, the EMP itself highlights that, ***"It is highly likely that several hundreds of right whales can be expected to pass through the Reconnaissance Permit Area when migrating southwards from the feeding areas between April and June"*** (page 93). Apart from this going against the spirit of avoiding whale periods by the oil and gas industry, Vermeulen *et al.* (2020) warned that there is an observed decrease in southern right whale calving success of the South African population and a strong link between foraging success and reproduction. They suggest an investigation into possible decreases and/or spatial or temporal shifts in their prey availability at higher latitudes due to environmental variability. They also highlight a concern of the continued low numbers of unaccompanied adults along the South African coast which could potentially have serious consequences for cow-calf pairs in relation to the country's whale-watching industry in the future.

Since 2011, South Africa has witnessed 'super-pods' of up to 200 humpback whales feeding in south and west coast waters between October to January. Research by the National DFFE, in collaboration with various academic partners, has led to the discovery of these 'feeding grounds' away from their traditional feeding grounds in the Antarctic[2]. This phenomenon

[2] https://www.news24.com/news24/travel/watch-whale-super-pods-larger-than-usual-cause-stir-off-sas-west-coast-public-urged-to-keep-their-distance-20191216

EXECUTIVE BOARD MEMBERS: Mr A Nicholls (Chairman), Mrs H Newton-King (Vice Chair), Mr P Bode, Mrs P Ellis, Dr C Fraser, Mr A Patel, Ms B Ratcheson, Mr N Bailey

requires understanding the ecosystem-wide impacts and benefits, while potential human/whale conflicts remain unknown. According to Dey et al. (2021), the formation of super-groups in recent years suggests that there might be a change in oceanographic or ecological characteristics which provide the conditions for this novel feeding strategy in the Southern Benguela Upwelling System. Although the humpback whale population is increasing (Wilkinson, 2021), there is evidence to suggest that cetaceans in South African waters are being affected by changes in their ecosystem and it is not well understood yet what is driving these changes and what the long terme effects could potentially be to populations.

With other mammals, it was suggested by Thompson et al. (1998) that grey seals displayed strong avoidance behavior, altered foraging behavior and suggested an increased frequency of hauling out onto land to possibly escape the noise, while harbor seals had slower heart rates during controlled playback experiments. In contrast, during a study in shallow arctic waters, sighting rates of ringed seals (*Phoca hispida*) from a seismic vessel showed no difference when a different number of airguns were in use, did however suggest local avoidances based on distance from the sound source (Harris et al., 2001).

In South Africa, the Cape fur seals (*Arctocephalus pusillus pusillus*), is the only resident seal along the west coast, occurring at numerous breeding and non-breeding sites on South Africa's mainland and on nearshore islands and reefs. Other vagrant seals occurring along the south and west coast include the southern elephant seal (*Mirounga leonines*), subantarctic fur seal (*Arctocephalus tropicalis*), *Antarctica fur seal* (*Arctocephalus gazella*), crabeater (*Lobodon carcinophagus*) and leopard seals (*Hydrurga leptonyx*). Cape fur seals are highly

mobile and have large foraging areas including on the continental shelf up to 120 nautical miles offshore (Shaughnessy 1979).

According to Kirkman et al. 2016, several morbillivirus epidemics have occurred in true seal (Phocid) populations in the northern hemisphere and, at the time it was agreed that no epidemic diseases were known to have infected Cape Fur Seals historically, but there was a considerable risk for disease transmission to the population through exposure to domestic or feral dogs and terrestrial carnivores, potentially resulting in mass mortality. Kirkman et al. (2016) cautioned that the health of individuals and their vulnerability to disease can be affected by feeding conditions, including the availability of prey, and that risk of disease may be exacerbated by anthropogenic pressures on the ecosystem.

In South Africa, since 10 September 2021, thousands of emaciated, dying and dead Cape fur seals (*Arctocephalus pusillus pusillus)*, have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. It is of concern that although the cape fur seal population within South Africa are healthy, they too are under pressure from various anthropogenic pressures, and the EMP failed to mention this mass die-off event

In South Africa, only a single focused study on the impact of seismic surveys has been undertaken. This study, off Gqeberha, was within the foraging area of the endangered, endemic African Penguin (*Spheniscus demersus*). Pichegru et al. (2017) demonstrated that penguins avoided their preferred foraging areas during seismic surveys and foraged further from the survey vessel when in operation. Upon termination of seismic surveys, the penguins reverted to their normal behaviour (Pichegru et al. (2017), a behaviour which was also

observed in Gray whales (*Eschrichtius robustus*) off Sakhalin Island in Russia (International Whaling Commission 2005). However, the long-term effects on populations of this temporary retreat of the area are unknown. Given the results of this study by Pichegru et al. (2017), strict management measures and decisions on seismic survey activities should have been established in South Africa. Furthermore, the cumulative effect of multiple, concurrent seismic surveys within the region may cause cumulative impacts.

Significant impacts on turtle species are a concern. Adult turtles may be less vulnerable to sound damage than cetaceans as the air spaces in their cochlear are smaller than those in cetaceans, making them less sensitive to sound shockwaves (Popper et al. 2014). However, while studies have shown that adult sea turtles have a moderate ability to move from an area being surveyed (Lenhardt 1994; O'Hara and Wilcox 1990), they are prone to TTS after exposure to sound within 1 km of a sound source, with signs of recovery only two weeks after injury (Lenhardt 1994). In a study undertaken on captive turtles, it was found that loggerhead turtles (*Caretta caretta*) responded to sound by swimming to the surface and remaining there or staying slightly submerged (Lenhardt 1994), as this area, regarded as a sound shadow, and is hypothesised as being where sound waves cancel each other out and the noise is at a minimum. Cummings et al. (2004) disputed this saying that although near the surface, could be a place where animals take refuge, they are not in a 'zone of silence'. With an increasing exposure of sound levels, the behaviour of caged green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) turtles increased their swimming speed, potentially showing agitation to sound (McCauley et al. 2000). Turtle behaviour is difficult to interpret (DeRuiter and Doukara 2012), given that some studies have reported that turtles do not display any signs of distress (Pendoley 1997). Globally the Leatherback turtle (*Dermochelys coriacea*) is vulnerable, but critically endangered in the Southwestern Indian Ocean where this subpopulation is declining

(Nel 2010, 2012; Nel et al. 2013). Loggerhead (*Caretta caretta*) populations are globally vulnerable but near threatened in the southwest Indian Ocean (Lombard & Kyle 2014).

The nesting grounds of the southern African loggerhead (*Caretta caretta*) and leatherback turtle (*Dermochelys coriacea*) populations are located on the east coast in iSimangaliso Wetland Park. In the Autumn months, adult turtles are moving towards their nesting beaches but stay inshore to avoid the north to south flowing Agulhas current. Once they have completed their laying of eggs, they leave the shore and into the current to be carried south once again, and by late March, they will be littered along the east and south coast in offshore waters. Both loggerhead and leatherbacks are known to occur within the reconnaissance permit area but known migration corridors of adult leatherbacks lie within the reconnaissance permit area. Harris et al. (2018) highlighted the migration path for leatherback turtles into the southeastern Atlantic (Agulhas-Benguela Corridor), through the reconnaissance permit area. Leatherback turtles inhabit deeper waters and are considered a pelagic species, traveling within the ocean currents. However, they have a moderate ability to avoid areas with an increase of noise in the water. According to Hays et al. (2004), these animals may dive to depths over 600 m and remain submerged for up to 54 minutes. Mitigation measures for turtles in seismic surveys include observers, although it is unclear how an observer would be able to observe these animals at such a distance (especially as large animals such as whales are only observed 44% of the time at best). A second mitigation measure, although only to be used if turtles are sighted by observers (EMP page 224), is to install 'turtle-guards' to prevent them from becoming entangled in the gear. These devices are accepted as being useful in terms of entrapment but not for sound in the water. Given the sighting probability of a turtle by an observer is minimal (as explained above) and that turtle guards are not a standard measure on the gear for this survey, these two mitigation measures are hardly justifiable.

Effectiveness of Mitigation [Marine Mammal Observers (MMO) and Passive Acoustic Monitoring (PAM)]

During the 2018 and 2019 humpback whale (*Megaptera novaeangliae*) migration period along the east coast of South Africa, Wilkinson (2021) estimated the relative abundance of migrating humpback whales sighted by trainer observers from two towers located 22m apart (both observers viewing the same area), located at 70m above sea level on a dune with a horizontal vantage length of approximately 20 km. Over the observation periods during the peak of migration, it was estimated that observers from both towers missed between 41–44% of whale groups while distance offshore decreased the probability of sightings. Assuming that the best percentage sighting (56%) was achieved within 1-5km of the observers' vantage point, then more than 40% of whales were missed. Given that this survey was done during the northward migration when mostly larger animals are present, the sighting success may be less when small calves are present as well (as would be the case in December). This begs the question of the efficacy and reliability of the mitigation method of Marine Mammal Observers (MMO), while assuming that whales (and other cetaceans) are thus regularly missed by MMOs and could be harmed.

Despite various organisations who provide MMO's on vessels having a zero tolerance policy of intimidation it is not uncommon for an MMO to complain that he/she has been subjected to coercion, harassment and intimidation. The EMPr states that: "*The MMO has the authority to stop*

the survey activities (including seismic shooting) in response to certain circumstances related to marine mammal risk. However, due to the cost associated with terminating activities (e.g.

EXECUTIVE BOARD MEMBERS: Mr A Hoorweg (Chairman), Mrs H Newton-King (Vice Chair), Mr P Bode, Mrs P Ellis, Mr E Phakathi, Mr A Patel, Ms S Kuzwayo, Mr N Baloyi

EXECUTIVE DIRECTORS: Dr P Hoets, Ms S Singh

an entire survey line may need to be repeated), it is recommended that the decision to terminate firing be made by the operator in consideration of the MMO's advice. The MMOs must provide full reporting of all termination decisions (including behaviour and distance of marine mammals) in a daily close out report (Part B, p.8)". This statement is highly problematic and reinforces the concern that "A risk-averse and cautious approach, which takes into account the limits of current knowledge about the consequences of decisions and actions", a principle of the National Environmental Management Act, 107 of 1998, will not be applied in full.

Furthermore, bearing in mind the examples above, i.e. blue and fin whales ceasing to sing, the use of Passive Acoustic Monitoring (PAM) technology to detect cetaceans is baseless if cetaceans do not vocalise. As per best practice, in an effort to improve mitigation, PAM technology is complemented by visual searching over an area of 500m around the vessel by qualified Marine Mammal Observers (MMO). This technique is, however, also fatally flawed because it cannot be used at night, during rain and in sea states more than three on the Beaufort Sea State Scale. Therefore, both PAM and MMO's are insufficient to detect, with certainty, cetaceans within the surrounding survey area and these types of mitigation will only be effective for all affected species if airgun firing ceases between sunset and sunrise, and adverse weather conditions that limit visibility.

The cumulative and long-term effects of seismic survey sound is not entirely understood (Jasny et al. 2005); however, it is accepted that ocean noise may have ecosystem-scale effects (Hildebrand, 2005) and the "knock-on" effects on animals, their prey and their predators will have consequences within the food chain (Koper and Plön 2012). It has been suggested that research and a critical review on mitigation measures (McCauley et al. (2017) as well as

a better understanding of ecosystem-scale effects of sound (Koper and Plön 2012), especially at the lower trophic levels are imperative. Considering the ecosystem services provided by the Benguela Current Marine Ecosystem and its associated diversity and biomass, mitigation and understanding should be a conservation imperative in South African marine waters. Up to now, there has been no effort in increasing the knowledge of the impact of these seismic surveys by industry or South African environmental departments despite them being known to have impacts on marine animals and having been undertaken in South African waters for a number of decades.

Proximity to Marine Protected Areas and Critical Biodiversity Areas

The reconnaissance permit area occurs adjacent to six Marine Protected Areas (MPAs) including the Orange Shelf Edge MPA, Child's Bank MPA, Benguela Muds MPA, Cape Canyon MPA, Robben Island MPA and the Southeast Atlantic Seamounts MPA and completely surrounds the Benguela Muds MPA (See EMP: Figure 7-20). It is a significant concern that there is no reference or mention of buffers-areas around the MPAs in the EMP, which allows the vessel to come within 1 km of these protected areas. This is of particular concern, given that the EMP indicates *the cumulative zone of impact for the 3D survey extends to 800 m for permanent threshold shifts (PTS) and to 6 000 m for temporary threshold shift (TTS) for physiological injury, and the cumulative zones for PTS and TTS while the 2D survey is 500 m and 5 000m, respectively.* For example, the reconnaissance permit allows the survey vessel to be active ~800 m from the edge of the Orange Shelf Edge MPA, which is designated as a sanctuary zone, at depths of 250-1500m. Therefore, this would be within the zone of TTS and very near to that of PTS for 2D surveys.

It should be noted that, according to the National Environmental Management: Protected Areas Act 57 of 2003: section 48A reads:

"48A Restriction of activities in marine protected areas:
Despite any other legislation, no person may in a marine protected area-
....
(e) in any manner which results in an adverse effect on the marine environment, disturb, alter or destroy the natural environment of disturb of alter the water quality or abstract sea water;
(f) carry on any activity which may have an adverse effect on the ecosystem of the area;…."

While it is acknowledged that the EMP states that only 2D seismic activities will take place near any MPAs, it cannot be ignored that the proposed seismic activity will still have potential adverse effects on the ecosystem within the area and disturb the natural environment.

Further to this, large portions of the reconnaissance permit area comprise of Critical Biodiversity Areas (CBA) both 1 and 2 (See EMP; Figure 7-21). CBA 1 areas are irreplaceable or near-irreplaceable, while CBA 2 are sites that are the best option available for representing the features in a spatial prioritisation (Harris *et al.* 2020). The primary of objective, and national policy, is that both CBA 1 and 2 areas remain in natural or near-natural states for conservation management, while portions of these areas be ear-marked for future MPAs.

Comments on Tosaco Energy Block 1 Exploration Right issued to

Tosaco Energy (Pty) Ltd (PASA Reference: 12/3/562)

Harris JM, Olbers JM, Wright K

6 April 2022

In preparing these comments, we have reviewed scientific literature on the physiological, behavioural and ecological impacts of seismic survey activities on marine wildlife. The body of peer-reviewed scientific literature on seismic surveys has grown over the last few decades in response to significant concerns about the impacts of these seismic surveys on the marine environment. Although scientists may debate the nature, magnitude and reach (distance away from the source of seismic blasts) of negative impacts of seismic surveys on marine fauna, the overwhelming majority of the multitude of peer-reviewed published scientific studies (over 536 studies on ocean noise, where the majority found negative effects on marine mammals, and/or adverse impacts on fish and invertebrates) demonstrate that harm is caused or is the most likely scenario. This is a tangible cause for concern and warrants a precautionary approach. The issue at hand is not whether harm will be caused but rather what the magnitude of that harm will be, and whether measures that would prevent or effectively mitigate this harm are in place and effective.

In this report we provide a summary as well as more detailed discussion of our findings from the available information and studies on the impacts of seismic activities on marine wildlife, both globally as well as specifically relevant to the survey area (the west coast of South Africa) and time of year (December to May) specified in the EIAR associated with the exploration right (including 2D/3D seismic survey) granted to Tosaco Ltd for Tosaco Energy Block 1. A list of relevant publications is provided at the end of this document for reference.

Having reviewed the available information we conclude that seismic surveys do cause harm to both species and ecosystems, and that significant direct harm to individual animals and harm to populations of endangered species is the most likely scenario in the case of this authorised seismic survey on the west coast of South Africa. Of specific concern is the impact on humpback whales and southern right whales which are still frequenting the west coast over this period, and the impact on critically endangered (leatherback) turtles (migration routes in the area), the critically endangered African Penguin (changes in foraging behaviour and impacts on fitness) and the Cape fur seal (and consideration of added stress in light of current mass die-offs). We conclude that this seismic survey is inadvisable due to the presence of these species in the area, the increasing anthropogenic pressures,

and the inability of the prescribed mitigation measures preventing harm to individuals/populations. We disagree with the findings of the Marine Specialist Report that impacts on all species both physiological and behavioural will be very low, because the mitigation mechanisms specified are not fully effective in preventing harm. Furthermore, recent literature provides credible concern about ecosystem/food-chain impacts of seismic surveys, which may, in turn, have impact on fisheries, the severity and localisation of which will depend on coincidences with spawning and juvenile recruitment events.

It is our opinion that the seismic survey should not have been authorised, and we recommend that further studies on the impacts of seismic activities in the South African context are carried out *in situ* before proceeding with further seismic surveys of this nature.

Summary of Findings

- Based on peer-reviewed scientific literature, it is clear that physical damage to marine animals, including soft tissue trauma damage, embolisms, damage to organs used in balance and orientation, concussions, haemorrhaging, decompression sickness and both temporary and permanent threshold shifts to hearing ability have been directly linked to the kind and level of sound emitted during this nature of seismic surveys.
- There is plausible evidence to suggest that seismic survey activity is likely to affect the conservation status and recovery of populations of vulnerable and threatened species including (IUCN Red listed species such as humpback and southern right whales), because sound and the ability to hear and interpret sound is critical for many species to reproduce (both vocalisations on breeding grounds and communications across large distances for mate detection). Therefore, it must be assumed that interference in sound perception or utilisation for communication (temporarily or permanently) has the potential to impact a species at the population level.
- Some species have been shown and documented to display physiological stress responses and behavioural changes to seismic activities, such as moving away rapidly, diving or remaining still. These responses are likely to increase their energy consumption and energy costs, reduce their time to forage, and/or affect their vulnerability to predation, thus having negative impacts on the survival of individuals (especially young or compromised animals) as well as the overall population growth and survival of a species (especially for threatened species that are already at risk of extinction).
- The impacts of seismic activities are most well studied for marine mammals, and evidence suggests that there are distinct avoidance responses such as leaving the area or ceasing to

undertake everyday activities such as feeding in preferred areas. This is likely to negatively impact the "fitness" of an affected animal.

- The only existing field study in South Africa (that we have been able to find) on the impacts of seismic activities in our waters is illuminating in this regard. It presents clear evidence that the endangered, endemic African penguins avoided preferred feeding sites when a seismic survey was active nearby. This is particularly of concern for a species that has had a 70% decrease in numbers over the past decade, is stressed by prey depletion creating a greater demand for them to forage further afield, and for which the prospect of extinction is significant.
- The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect the survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.
- Research has demonstrated significant mortality in zooplankton up to 1.2 km from a seismic survey array. Zooplankton forms the base of many important food webs in the marine environment. Depletion of zooplankton could thus have an impact on food for their predators (such as fish) as well as impact fish eggs and larvae (ichthyoplankton) with potential local impacts on species important in fisheries. This damage to zooplankton over 1km away from the survey array raises concern that a 500m buffer for other animals that are unable to move away from the sound, is far too small to ensure that damage is not inflicted (even if they were able to evade it).
- The impact on fish assemblages is difficult to interpret, due to multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. A global review of the effect of seismic activities on fish and invertebrates acknowledged the limits of the current research due to experimental designs used or due to the focus on single species during investigations. A key concern is a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys that have been previously identified may be reflective of underestimation or overestimation and would depend on the type of interaction (synergistic, additive, or antagonistic).
- In South Africa, since October 2021, thousands of dead and/or dying Cape fur seals (*Arctocephalus pusillus pusillus*), have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. It is of concern that although the cape fur seal population within

South Africa is relatively healthy, they too are under pressure from various anthropogenic pressures. Additional stress from seismic activity at this time is inadvisable.

- While "Soft starts" as mitigation for seismic impacts are likely to reduce the impact for highly mobile large animals, this is unlikely to be adequate for the many species that are prevalent in the area over the austral summer months and are unable to avoid the array or leave the area due to their lower mobility, such as smaller turtles, penguins, invertebrates, some fish species and zooplankton.
- The finding of observer efficiency (from a scientific monitoring study conducted during the 2018/19 and 2019/2020 seasons on the humpback whales on the east coast) suggests that even with trained observers up to 44% of humpback whales in an area went undetected. This casts doubt on the effectiveness and success of Marine Mammal Observer (MMO) sightings of the largest species (humpbacks) as a mitigation measure, indicating that it is most likely that whales go undetected. Furthermore, the detection rate for smaller species, such as dolphins, seals, turtles and flightless birds (penguins), would be expected to be much lower, obviating the effectiveness of visual observations to prevent harm to these species.
- Also of concern, is that the efficacy of Marine Mammal Observers (MMO) is likely to be low due to the nature of the offshore marine environment in the survey area (frequent high swells and winds affecting surface visibility), putting species that are missed by MMO's and PAM operators at extreme risk, particularly at night or during adverse weather conditions.
- Furthermore, the reliance on Observers to do visual sightings to supplement the PAM monitoring during the day, as a mandated mitigation measure, necessitates that we question the acceptability of continuing with survey activities at night. If the visual observations are useful (perhaps sighting large animals around 65% of the time) in addition to PAM, then it is unreasonable to rely on PAM alone at night. It is our opinion that surveys should not occur between sunset and sunrise each day if a real attempt for maximum avoidance of cetaceans is the objective of this mitigation measure.
- It is of our opinion that the proposed seismic survey activities are highly likely to both disturb and have an adverse effect on Marine Protected Areas (MPA) and Critical Biodiversity Areas (CBA). It should be noted that the MPA in question, the Orange Shelf MPA, provides key feeding grounds for the endangered Atlantic Yellow-nosed Albatross, the near-threatened Black-browed Albatross and the critically endangered Tristan Albatross.

Global context – impacts of seismic surveys on marine wildlife

Despite seismic surveys having been undertaken for decades in South African waters, together with the knowledge that some impact to marine fauna does indeed occur[1], there remains very little scientific research on the effects of seismic surveys, and in addition there are no legislated guidelines for seismic surveys in South African waters (Purdon 2018). Globally, seismic surveys' environmental impacts and consequences are slightly better documented, although not uniform in results or widely accepted within all sectors. The primary mitigation measures for seismic surveys in South Africa include soft-starts, which is a gradual and systematic increase in power of the airgun array undertaken to warn and drive mobile marine species, such as cetaceans (whales and dolphins), seals, flightless birds and turtles away from the sound source before the full-power airgun blasts begin, thus attempting to minimise the negative effects of the airgun blasting activity. Various studies contest this assumption (McCauley et al. 2000; Weilgart 2013; Dunlop et al. 2016) and have revealed a growing concern for animals that are unable to avoid or out-swim the airgun arrays.

Animals use sound critical to their life cycles (Jasny et al. 2005) in three ways, by actively producing sound (Tyack 1981), by listening to sounds emitted by other living organisms (Clark et al. 2009; Van Opzeeland 2010) and taking cues from physical or non-living factors producing sounds, contributing to the ambient background noise, such as wind, waves, swell, bubbles, currents, turbulence, earthquakes, rainfall, ice cracking or breaking (Hildebrand 2005). Many marine animals produce sound for communication, reproduction, aggression, defence mechanisms, antagonistic interactions, courtship, group coordination, orientation, navigation, and prey identification (Hildebrand 2005). They rely on producing a sound that is heard while hearing a sound and interpreting the sound for their survival.

Various physical responses to acoustic disturbance have been documented, with physical responses including soft tissue damage (Balcom and Claridge 2001), embolisms (Dolman and Simmonds 2005), damage to organs used in balance (André et al. 2011), concussions in penguins (Cooper 1982), haemorrhaging (Evans et al. 2001) and decompression sickness (Fernández et al. 2005). Hearing impairment in the form of Temporary Threshold Shift (TTS) or Permanent Threshold Shift (PTS) has also been reported (Hildebrand 2005). Threshold shift refers to an increase in the minimum sound level required for an animal to hear a sound. A TTS is followed by successful recovery to normal hearing thresholds after a given period of time in the absence of that sound, while PTS is when the sensory

[1] https://jncc.gov.uk/our-work/marine-mammals-and-noise-mitigation: "to reduce the risk of deliberate injury to marine mammals".

hair cells in the inner ear are permanently damaged and lost making recovery impossible (Weilgart 2013).

Stress caused by disturbance is associated with a change in body chemistry (Jasny et al. 2005) and can be equally disruptive as physical damage. Stress has implications on sexual maturation, inhibits growth, reproduction and general survival ability (Pickering 1992; McCormick 1999; Consten et al. 2001). Perceptual effects can occur when there is an interference of sounds of interest to a specific animal but are being drowned out or masked by anthropogenic noise. The impact of this in the long term could have implications on breeding populations, thus on reproduction within a population (Erbe 2001). Many animals may have the ability to counteract this and make minor changes to their vocalisations and behaviour; however, these modifications may come at a cost in terms of energy expenditure (Tyack 2008) and are likely to reduce breeding productivity of the population. This is of particular concern for species that are threatened.

Behavioural responses to noise are dependent on various factors, such as age, sex, presence of offspring, location and an individual animals' previous encounter with a specific sound or noise. Behavioural responses may include modification of vocal behaviour, displacement from important habitats, and other subtle responses, including increased breathing rates, change in dive duration, time spent at the surface, rapid or erratic movements (Bowles et al. 1994; Lesage et al. 1999; Williams et al. 2002; Hastie et al. 2003; Ng and Leung 2003; Aguilar de Soto et al. 2006). These all with potentially high energetic costs (Williams et al. 2006; Koper and Plön 2012).

Most scientific research on the impacts of seismic surveys has been conducted on cetaceans, and as a result, most mitigation measures are to protect these animals. In South Africa, this is no different. However, it is becoming more and more evident that mitigation measures are not adequate (Weilgart 2013). In the Gulf of Mexico, it was recorded that ~250 male fin whales appeared to stop singing for several weeks to months during a seismic survey. These animals resumed singing within hours or days after the survey ended (IWC 2007). The assumption is that male fin whales use vocalisations for reproduction by finding and attracting mates (Croll et al. 2002); it can only be assumed that such an effect would be biologically significant (Weilgart 2013). In addition to this, a blue whale ceased calling in the presence of a seismic survey at 10 km away (Macdonald et al. 1995). Conversely, a different group of blue whales appeared to have the opposite reaction. They changed their vocalisations (De Lorio et al. 2010) by calling consistently more on days when the seismic surveys were actively ongoing.

suggesting that seismic survey noise interfered with important signals used in their social interactions and feeding (De Lorio et al. 2010).

Other reactions to seismic airguns can be subtle or hard to detect (Weilgart 2013) and it has been found that Sperm whales in the Gulf of Mexico did not appear to avoid a seismic airgun survey area but reduced their swimming effort and their tendency to reduce foraging effort (Miller et al. 2009). It has also been documented that as a result of changes in behaviour, the result could be lower reproductive rates and have negative consequences for the population (Miller et al. 2009). In comparison, bowhead whales showed no avoidance or change in vocalisations in the area of seismic surveys; however, their dive duration was shorter (Richardson et al. 1986). In Brazil, a reduction in cetacean species diversity during 2000 and 2001 was noted with the increased occurrence of seismic surveys in the area being implicated in the possible cause of these animals vacating the area (Parente et al. 2007). In other areas, marine mammals have been recorded to avoid seismic noise by leaving an area (Castellote et al. 2012; Weir 2008; Stone and Tasker 2006). The long-term impacts of various changes in behaviour are largely unknown but potentially impact their ability to feed and/or reproduce as in some species, these life-history stages are site or habitat-specific.

South Africa's south and west coasts are host to eight species of beaked whales (Ziphiidae) (Best 2007), including a new species described in 2021 (*Mesoplodon eueu*; Carroll et al. 2021), which are globally recognised as being sensitive to anthropogenic noise, and having raised conservation concerns. New et al. (2013) found that adult female beaked whales could survive but not reproduce in times or areas of lower habitat quality. They may extend the duration of lactation in mediocre conditions to increase their chance of survival, while still reproducing. New et al. (2013) found that some beaked whale species require high-quality habitat to meet their requirements for reproduction and survival. They suggested that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.

McEwen and Wingfield (2003) suggested that all organisms must gather energy for growth and reproduction throughout their life cycle and that organisms must retain reserves for predictable changes such as seasons, and challenges that are less predictable such as disturbance, predation pressure, or social conflict. Often colloquially, this is referred to as the "fitness" of the animal. The accumulated cost in the balance between energy intake and demand is called the 'allostatic load', of physiological and behavioural mechanisms that enable allostasis or adaptation to these changes. McEwen and Wingfield (2003) use the word "allostasis" to signify mechanisms that allow an organism

to regain equilibrium while dealing with external challenges; if energy demand is more than intake, then animals may activate a survival mode that may increase energy available, reduce energy demand, or both, to regain its energy balance. Implications on individuals and populations of this energy imbalance are unknown.

Several studies have reported negative impacts of acoustic signals from airguns on zooplankton (small, aquatic microorganisms living in the water column, including crustaceans, larvae, juvenile fish, juvenile invertebrates, eggs etc.) from more than 10 m away (Kostyuchenko 1972; Kosheleva 1992; Parry *et al.* 2002) with some laboratory experiments on lobster larvae showing no impact at all (Day *et al.* 2016). However, Christian *et al.* (2003), showed retardation in some individuals in the development of snow crab eggs after being exposed to certain sound levels.

The effects of seismic noise on zooplankton were brought under the spotlight when McCauley *et al.* (2017) presented evidence from an *in-situ* study that suggested that seismic surveys cause significant mortality to zooplankton populations. Zooplankton, unlike vertebrates, do not have hearing structures (although they can sense pressure change) and their bodies are generally the same density as the surrounding water, so sudden pressure changes associated with seismic activities were presumed not to cause physical damage (Parry and Gason 2006). McCauley *et al.* (2017) disputed this and has shown zooplankton mortality at distances of up to 1.2 km from the sound source.

Similarly, inconsistent findings occur with fish assemblages. The impacts on fish assemblages are difficult to interpret, because of multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. We acknowledge the validity of the results presented by Meekan et al. (2021) which highlights that exposure to an experimental seismic source did not have an impact on the assemblage of tropical demersal fishes found along the northwest shelf of Western Australia. However, it must be noted that the findings have been stated to be applicable only to other habitats with similar physical environments, in particular similar water depths (50 – 70 m), highlighting the need for South African-specific and local research to be undertaken.

A global review of the effect of seismic activities on fish and invertebrates by Carroll et al. (2017) acknowledged the limits of the available research due to experimental design, or to the focus on single species which prevents extrapolation to other regions, other seismic surveys, species, or biological responses. In addition, they highlighted a serious concern, that there was a lack of research focused

on confounding effects and multiple stressors, therefore potential impacts of seismic surveys which had previously been identified may be reflective of under-estimation or over-estimation and would depend on the type of interaction (i.e., synergistic, additive, or antagonistic).

Furthermore, the indirect effects of seismic activity on cetaceans are a concern. It is well known that the productivity and health of the oceans are under-pinned by marine plankton (Raymont 1983; Alcaraz & Calbet 2009). While forming the basis of the food webs, plankton has been implicated in links to climate change via their role in iron fertilisation and carbon sequestration through whales foraging on krill and subsequent defecation (Smetacek and Nicol 2005; Smetacek 2008; Nicol et al. 2010). In 2010, Pershing et al. suggested that over-fishing of large fish and commercial whaling had compromised the ocean's ability to store and sequester carbon, thus contributing to climate change. They indicated that populations of large baleen whales now store 9.1×106 tonnes less carbon than before commercial whaling and that protecting whales (and other large over-exploited species), would be a form of a carbon management scheme. The cascading and knock-on effects of seismic survey impacts between the upper (cetaceans) and lower reaches (plankton) of the food web, as each are being impacted are unknown. McCauley et al. (2017) noted that the ramifications of compromised larval recruitment could be massive for higher predators and for ocean health as a whole. While traditional feeding grounds for humpback whales are in Antarctic waters, Dey et al. (2021) has recently recorded regular feeding frenzies off the west coast in recent years (see super pods below).

South African Context

It is of concern that no acoustic modelling was undertaken for the proposed seismic survey activity. Where the impact of sound was referred to in the EIAR, it appears that the most conservative estimates of impacts are used, with statements in the Marine Specialist Report (Pg. 9) including "Based on analogue sound sources, sound levels for the seismic survey can notionally be expected to attenuate below 160 dB less than 1,325 m from the source array." However, the author then goes on to sight multiple examples of behavioural responses of species outside of this range including but not limited to cephalopods (2-5km, pg. 81), fish (up to 5km, pg. 88), turtles (up to 3.5 km pg. 103), cetaceans (beyond 5 km, and potentially displaying avoidance responses at 24km, pg. 118). It thus becomes very difficult to accurately assess risk without this critical piece of information, however there are some key concerns.

It is of concern that there are a number of 'unknowns' and 'warning bells' in terms of presence of and impacts on cetacean populations on the west coast. Despite various species being recorded frequently on the coast, the location of breeding grounds of Sei (*Balaenoptera borealis*) and Fin whales (*Balaenoptera physalus*) are unknown, the seasonality of pygmy (*Kogia breviceps*) and dwarf (*Kogia sima*) sperm whales are unknown and the abundance and occurrence of the offshore common dolphin (*Delphinus delphis*) is also unknown, highlighting that encounters with these animals cannot be predicted and the generic mitigation measures may be insufficient. Further to this, it is noted in the EIAR for the Tosaco exploration right that the two very well-studied and frequently observed species on the south and west coasts, the humpback and southern right whales, are expected to be regularly encountered and have a year-round occurrence in the seismic survey area. The period of humpback whales in this area is between July and February, with frequent feeding encounters during the months between December to February. Barendse et al. (2010), Best & Allison (2010), and Elwen et al. (2014) highlighted that there is no existing evidence of a clear 'corridor' of migration and humpback whales appear to be spread out widely across the shelf and into deeper pelagic waters, especially during the southward migration, in the Benguela ecosystem. Apart from this going against the spirit of avoiding whale periods by the oil and gas industry, Vermeulen *et al.* (2020) warned of an observed decrease in southern right whale calving success of the South African population and a strong link between foraging success and reproduction. They suggest an investigation into possible decreases and/or spatial or temporal shifts in their prey availability at higher latitudes due to environmental variability. They also highlight a concern of the continued low numbers of unaccompanied adults along the South African coast which could potentially have serious consequences for cow-calf pairs in relation to the country's whale-watching industry in the future.

Since 2011, South Africa has witnessed 'super-pods' of up to 200 humpback whales feeding in south and west coast waters between October to January. Research by the National DFFE, in collaboration with various academic partners, has led to the discovery of these 'feeding grounds' away from their traditional feeding grounds in the Antarctic[2]. This phenomenon requires understanding the ecosystem-wide impacts and benefits, while potential human/whale conflicts remain unknown. According to Dey et al. (2021), the formation of super-groups in recent years suggests that there might be a change in oceanographic or ecological characteristics which provide the conditions for this novel

[2] https://www.news24.com/news24/travel/whale-whale-super-pods-larger-than-usual-count-sit-off-sas-west-coast-public-urged-to-keep-their-distance-20191218

feeding strategy in the Southern Benguela Upwelling System. Although the humpback whale population is increasing (Wilkinson, 2021), there is evidence to suggest that cetaceans in South African waters are being affected by changes in their ecosystem and it is not well understood yet what is driving these changes and what the long terms effects could potentially be to populations.

With other mammals, it was suggested by Thompson et al. (1998) that gray seals displayed strong avoidance behavior, altered foraging behavior and suggested an increased frequency of hauling out onto land to possibly escape the noise, while harbor seals had slower heart rates during controlled playback experiments. In contrast, during a study in shallow arctic waters, sighting rates of ringed seals (*Phoca hispida*) from a seismic vessel showed no difference when a different number of airguns were in use, did however suggest local avoidances based on distance from the sound source (Harris et al., 2001).

In South Africa, the Cape fur seals (*Arctocephalus pusillus pusillus*), is the only resident seal along the west coast, occurring at numerous breeding and non-breeding sites on South Africa's mainland and on nearshore islands and reefs. Other vagrant seals occurring along the south and west coast include the southern elephant seal (*Mirounga leonina*), subantarctic fur seal (*Arctocephalus tropicalis*), *Antarctica fur seal* (*Arctocephalus gazella*), crabeater (*Lobodon carcinophagus*) and leopard seals (*Hydrurga leptonyx*). Cape fur seals are highly mobile and have large foraging areas including on the continental shelf up to 120 nautical miles offshore (Shaughnessy 1979).

According to Kirkman et al. 2016, several morbillivirus epidemics have occurred in true seal (Phocid) populations in the northern hemisphere and, at the time it was agreed that no epidemic diseases were known to have infected Cape Fur Seals historically, but there was a considerable risk for disease transmission to the population through exposure to domestic or feral dogs and terrestrial carnivores, potentially resulting in mass mortality. Kirkman et al. (2016) cautioned that the health of individuals and their vulnerability to disease can be affected by feeding conditions, including the availability of prey, and that risk of disease may be exacerbated by anthropogenic pressures on the ecosystem.

In South Africa, since 10 September 2021, thousands of emaciated, dying and dead Cape fur seals (*Arctocephalus pusillus pusillus*), have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. It is of concern that although the cape fur seal population within

South Africa are healthy, they too are under pressure from various anthropogenic pressures and the seismic survey is likely to add stress to the population.

In South Africa, only a single focused field study on the impact of seismic surveys has been undertaken. This study, off Gqeberha, was within the foraging area of the endangered, endemic African Penguin (*Spheniscus demersus*). Pichegru et al. (2017) demonstrated that penguins avoided their preferred foraging areas during seismic surveys and foraged further from the survey vessel when in operation. Upon termination of seismic surveys, the penguins reverted to their normal behaviour (Pichegru et al. 2017), a behaviour which was also observed in Gray whales (*Eschrichtius robustus*) off Sakhalin Island in Russia (International Whaling Commission 2005). However, the long-term effects on populations of this temporary retreat of the area are unknown. Given the results of this study by Pichegru et al. (2017), strict management measures and decisions on seismic survey activities should have been established in South Africa. Furthermore, the cumulative effect of multiple, concurrent seismic surveys within the region may cause cumulative impacts.

Significant impacts on turtle species are a concern. Adult turtles may be less vulnerable to sound damage than cetaceans as the air spaces in their cochlear are smaller than those in cetaceans, making them less sensitive to sound shockwaves (Popper et al. 2014). However, while studies have shown that adult sea turtles have a moderate ability to move from an area being surveyed (Lenhardt 1994; O'Hara and Wilcox 1990), they are prone to TTS after exposure to sound within 1 km of a sound source, with signs of recovery only two weeks after injury (Lenhardt 1994). In a study undertaken on captive turtles, it was found that loggerhead turtles (*Caretta caretta*) responded to sound by swimming to the surface and remaining there or staying slightly submerged (Lenhardt 1994), as this area, regarded as a sound shadow, and is hypothesised as being where sound waves cancel each other out and the noise is at a minimum. Cummings et al. (2004) disputed this saying that although near the surface, could be a place where animals take refuge, they are not in a 'zone of silence'. With an increasing exposure of sound levels, the behaviour of caged green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) turtles increased their swimming speed, potentially showing agitation to sound (McCauley et al. 2000). Turtle behaviour is difficult to interpret (DeRuiter and Doukara 2012), given that some studies have reported that turtles do not display any signs of distress (Pendoley 1997). Globally the Leatherback turtle (*Dermochelys coriacea*) is vulnerable, but critically endangered in the Southwestern Indian Ocean where this subpopulation is declining (Nel 2010, 2012; Nel et al. 2013). Loggerhead (*Caretta caretta*) populations are globally vulnerable but near threatened in the southwest Indian Ocean (Lombard & Kyle 2014).

Both loggerhead and leatherbacks are known to occur within the Tosaco 2D/3D seismic survey area but known migration corridors of adult leatherbacks lie just offshore of the survey area. Harris et al. (2018) highlighted the migration path for leatherback turtles into the south-eastern Atlantic (Agulhas-Benguela Corridor), adjacent to the survey area. Leatherback turtles inhabit deeper waters and are considered a pelagic species, traveling within the ocean currents. However, they have a moderate ability to avoid areas with an increase of noise in the water. According to Hays et al. (2004), these animals may dive to depths over 600 m and remain submerged for up to 54 minutes. Mitigation measures for turtles in seismic surveys include observers, although it is unclear how an observer would be able to observe these animals at such a distance (especially as large animals such as whales are only observed 44% of the time at best). A second mitigation measure, is to install 'turtle-guards' to prevent them from becoming entangled in the gear. These devices are accepted as being useful in terms of entrapment but not for sound in the water. Given the sighting probability of a turtle by an observer is minimal (as explained above) and that turtle guards are recommended gear, not compulsory for this survey, these two mitigation measures do not instil confidence that impacts on turtles are effectively mitigated.

Effectiveness of Mitigation (Marine Mammal Observers (MMO) and Passive Acoustic Monitoring (PAM))

During the 2018 and 2019 humpback whale (*Megaptera novaeangliae*) migration period along the east coast of South Africa, Wilkinson (2021) estimated the relative abundance of migrating humpback whales sighted by trainer observers from two towers located 22m apart (both observers viewing the same area), located at 70m above sea level on a dune with a horizontal vantage length of approximately 20 km. Over the observation periods during the peak of migration, it was estimated that observers from both towers missed between 41-44% of whale groups while distance offshore decreased the probability of sightings. Assuming that the best percentage sighting (56%) was achieved within 1-5km of the observers' vantage point, then more than 40% of whales were missed. Given that this survey was done during the northward migration when mostly larger animals are present, the sighting success may be less when small calves are present as well (as would be the case in December). This begs the question of the efficacy and reliability of the mitigation method of Marine Mammal Observers (MMO), while assuming that whales (and other cetaceans) are thus regularly missed by MMOs and could be harmed.

Furthermore, bearing in mind the examples above, i.e., blue and fin whales ceasing to sing, the use of Passive Acoustic Monitoring (PAM) technology to detect cetaceans is baseless if cetaceans do not vocalise. As per best practice, in an effort to improve mitigation, PAM technology is complemented by visual searching over an area of 500m around the vessel by qualified Marine Mammal Observers (MMO). However, this technique is also fatally flawed because it cannot be used at night, during rain, and effectively in sea states more than three on the Beaufort Sea State Scale. Therefore, both PAM and MMO's are insufficient to detect, with certainty, cetaceans within the surrounding survey area and these types of mitigation will only be effective for all affected species if airgun firing ceases between sunset and sunrise, and adverse weather conditions that limit visibility.

The cumulative and long-term effects of seismic survey sound are not entirely understood (Jasny et al. 2005); however, it is accepted that ocean noise may have ecosystem-scale effects (Hildebrand, 2005) and the "knock-on" effects on animals, their prey and their predators will have consequences within the food chain (Koper and Plön 2012). It has been suggested that research and a critical review on mitigation measures (McCauley et al. (2017) as well as a better understanding of ecosystem-scale effects of sound (Koper and Plön 2012), especially at the lower trophic levels are imperative. Considering the ecosystem services provided by the Benguela Current Marine Ecosystem and its associated diversity and biomass, mitigation and understanding should be a conservation imperative in South African marine waters. Up to now, there has been no effort in increasing the knowledge of the impact of these seismic surveys by industry or South African environmental departments despite them being known to have impacts on marine animals and having been undertaken in South African waters for a number of decades.

Proximity to Marine Protected Areas and Critical Biodiversity Areas

The authorised Tosaco Block 1 exploration right area encompasses a proportion the Orange Shelf Edge MPA, and completely surrounds the Namaqua Fossil Forest MPA (See EIAR Figure 14 pg. 41). While it is noted that a 5 km buffer has been included around these MPAs in relation to the associated 2D/3D seismic survey, there is still cause for concern as the impact of noise from the array can influence the behaviour of some species at distances of over 5 km. The marine specialist report continually identifies the impact on marine species to be no more than 1.5 km, with impacts on fisheries of up to 5 km from the sound source. However, a report on seismic operations from a proposed vessel in the same area (Searcher), using the same technology indicated *"the cumulative zone of impact for the 3D survey extends to 800 m for permanent threshold shifts (PTS) and to 8 000 m for temporary threshold shift (TTS) for physiological injury, and the cumulative zones for PTS and TTS while the 2D survey is 500 m*

and 5 000m, respectively". The Orange Shelf MPA forms key feeding grounds for the endangered Atlantic Yellow-nosed Albatross, the near-threatened Black-browed Albatross and the critically endangered Tristan Albatross (Birdlife International unpublished data) and it provides an important foraging and aggregating area for cetaceans and large fish species. A significant concern should seismic activities occur nearby. Furthermore, the 2D/3D survey area abuts the Namaqua Fossil Forest MPA, meaning that the vessel will be active for an extended period, up to four months, in very close proximity to the MPA.

It should be noted that, according to the National Environmental Management: Protected Areas Act 57 of 2003: section 48A reads:

"48A Restriction of activities in marine protected areas:

Despite any other legislation, no person may in a marine protected area-

....

(e) in any manner which results in an adverse effect on the marine environment, disturb, alter or destroy the natural environment of disturb of alter the water quality or abstract sea water;

(f) carry on any activity which may have an adverse effect on the ecosystem of the area;...."

It cannot be ignored that the proposed seismic activity will still have potential adverse effects on the ecosystem within the area and disturb the natural environment.

Further to this, large portions of the Tosaco exploration right area comprise Critical Biodiversity Areas (CBA) both 1 and 2, with a significant proportion of the 3D area comprising CBA 1 and 2. CBA 1 areas are irreplaceable or near-irreplaceable, while CBA 2 are sites that are the best option available for representing the features in a spatial prioritisation (Harris *et al.* 2020). The primary of objective, and national policy is that both CBA 1 and 2 areas remain in natural or near-natural states for conservation management, while portions of these areas be ear-marked for future MPAs.

Curriculum Vitae

JEAN MARY HARRIS

PERSONAL DETAILS

Name	:	Jean Mary Harris
Birth date	:	28 December 1962
ID Number	:	6212280006086
Place of birth	:	Johannesburg
Nationality	:	South African
Race	:	White
Gender	:	Female
Address	:	49 Netford, Bluff, Durban, 4052, KZN South Africa
Tel	:	+27-61-4219638 (w), 082-4954416
e-mail	:	jeanh@wildtrust.co.za or jmharris@iafrica.com

EDUCATION

1993 PhD (Zoology), University of Cape Town. Focus: Trophic ecology in estuarine and intertidal systems.
1984 B.Sc. Hons. (Marine Biology), University of Cape Town, First Class
1982 B.Sc. (Zoology), University of Cape Town
1979 Matriculated, A-grade, Clarendon Girls High School, East London

AWARDS:

- PEW Fellowship in Marine Conservation, 2000
- Purcell Memorial Prize for best Zoology PhD thesis, 1993
- FRD Special Merit Doctoral Award, 1990

SELECTION OF PROFESSIONAL OFFICES HELD

Pew Fellow in Marine Conservation, Pew Fellows Program in Marine Conservation, 2000 - present
Trustee: South African Association for Marine Biological Research, 2016- July 2017
Member: Programme Steering Committee for the Marine Science for Management Association (MASMA), Western Indian Ocean Marine Science Association (WIOMSA) 2004-2015.
Chair: Subsistence Fisheries Task Group 1999-2000.
Chair: SA Network for Coastal and Oceanographic Research (SANCOR) National Steering Committee 1997-2001.
Member: IUCN Species Survival Commission – Marine Conservation Committee, 2018-present
Member: IUCN SSC Red List Committee, 2018-2021
Executive Trustee: Wetlands Conservation Trust, 2015- April 2017
Member: Scientific Authority 2014-2017. Advises the SA Minister of Environment on biodiversity matters
Chair: Symposium of Contemporary Conservation Practice (SCCP) 2012- July 2017.
Member: East African Marine EcoRegion Programme Committee (EAME) 2004-2010

EMPLOYMENT RECORD

Executive Director WILDOCEANS, Wildlands Conservation Trust, August 2017 - current
Research Associate, Institute for Coastal and Marine Research, Nelson Mandela University, 2016-present
Senior General Manager: Scientific Services, Ezemvelo KZN Wildlife, October 2006 – July 2017
Ecological Advice Co-ordinator, Coast Region, Ezemvelo KZN Wildlife, 2002- September 2006
Regional Ecologist Marine/Scientist, Scientific Services, KZN Nature Conservation Service, 1995 – 2002
Senior Scientific Officer, Terrestrial Antarctic Biology Research Programme, Ornithology, UCT, 1991-1994

SELECTION OF RESEARCH AND MANAGEMENT EXPERIENCE

Project Leader Blue Action Fund "Oceans Alive" iSimangaliso MPA Project (2019-current): This project has 3 main objectives 1) Build knowledge of the biodiversity and socio-economics of the MPA and its communities, 2) Support effective management of the iSimangaliso MPA, and 3) Ensure benefits and improved livelihoods for rural communities living alongside the iSimangaliso MPA.

Directs the following WILDOCEANS projects for the Wildlands Conservation Trust (2017-current): Ocean Stewards, WhaleTime, MPA Expansion Project, Shark and Ray Conservation Project, Comoros Fish and Benthic Biodiversity Project, iSimangaliso Oceans Alive (MPA expansion, effective management and benefits to communities) Project, Blue Crew project in the Durban bay estuarine environment (plastic pollution action).

Principle Investigator and Co-ordinator for NRF-funded African Coelacanth Ecosystem Programme research projects: Biodiversity Surrogacy (2014-2017), Spatial Solutions (2016-2018) and Canyon Connections (2018-2020). Offshore biodiversity survey and sampling to test validity of modelled biozones, to refine conservation planning, and to support marine protected area expansion and the National Biodiversity Assessment (CBD).

Project leader for WWF-SA, NRF and ACEP funded project: SeaPLAN – development of a systematic conservation plan for the east coast of South Africa (2004-2012). Integrates shoreline biodiversity mapping, reef biodiversity surveys and key species and processes.

Project leader Wildlands Trust funded project: Rare and Endangered Species of the Greater St Lucia Wetland Park (2002-2005). This project aims to update the records of these species in the park and provide a management handbook. It is focussed on terrestrial and freshwater wetland species and employs a full-time researcher. This project has become entrenched and is ongoing.

Project leader for NRF funded project: KwaZulu-Natal and Transkei Indigenous knowledge of subsistence harvesters (2002-2006): Aims to document traditional knowledge and management systems of rural subsistence harvesters, compare regional differences, and integrate into current management practices.

Chairperson of Subsistence Fisheries Task Team, on behalf of Marine and Coastal Management (DEAT), managed a national programme for coast-wise identification of and consultation with subsistence fishers (1999-2000). Acted as Program manager and supervisor of 8 Regional Fieldworkers (Northern Cape, West Cape (x2), South coast, Eastern Cape (x2), KwaZulu-Natal (x2), and a National Co-ordinator and project researcher. – Project leader and finance vote-holder (ca R1 mill)

Project executant (co-ordinator & researcher, and supervisor of 2 project staff) for 5-year project funded by The Green Trust, WWF-SA: The development of sustainable utilization of roussels by artisanal and subsistence gatherers along the northern KwaZulu-Natal coast – Sokhulu community alongside iSimangaliso 1995-2000.

POST-GRADUATE STUDENT SUPERVISION:

6 MSc and 2 PhD students

PUBLICATION SUMMARY:

Papers in refereed journals:	37
Book/ book chapter	8
Reports and Popular articles	10

SKILLS

- Class IV Commercial Diver (2004).
- SAMSA Skipper - Category C [Surf Launch] (2017)
- SAMSA Short Range VHF Radio Operators Certificate (2017)
- IMO* STCW* Basic (in progress; awaiting the end of lockdown)
- First aid - Level 3 (in-date).
- Quantum GIS (2015)

Profile

A marine scientist with a keen interest in marine biodiversity. I have a proven knowledge of essential scientific skills and technical experience, including data collection, data analysis, as well as worthy presentation and report writing skills. This resume validates my excellent work ethic and personal attributes, including sound organizing and planning skills, together with the ability to work both independently or in a team.

Education

PhD (Zoology) - 2016
University of Cape Town, South Africa.
Taxonomy, biodiversity and biogeography of the brittle stars (Echinodermata: Ophiuroidea) of South Africa.

MSc (Biological Sciences) - 2006
University of KwaZulu-Natal, Oceanographic Research Institute.
Zonation of the benthic communities on Aliwal Shoal, KZN, South Africa.

BSc Hons (Marine Ecology) - 2003
University of Natal, Durban.
Age, growth and stock assessment of Otolithes ruber from KwaZulu-Natal, South Africa.

BSc degree (Natural and Environmental Sciences) - 2002
Rand Afrikaans University.

Higher Certificate in Environmental Law and Liabilities for the Regulated Community - 2019
University of South Africa.

Employment History

Wildlands Conservation Trust - Marine Conservation Scientist - August 2020 - Present
Provide scientific oversight on the WILDOCEANS Shark and Ray Protection Project, funded by the Shark Conservation Fund.

Ezemvelo KZN Wildlife - Marine Ecologist - 2007 - 2020.
Provide ecological advice and decision support to conservation managers on priority biodiversity information needs in KZN. Develop and implement biological monitoring programmes for several marine ecosystems and resources. Contribute to policy development, guidelines and legislation tackling marine biodiversity conservation concerns. Provide training to field staff on aspects of marine protected areas, threatened and protected species and marine resources. Liaise with external organisations on issues relating to marine research and the marine environment.

* IMO (International Maritime Organisation)
* Standards of Training, Certification and Watchkeeping

Oceanographic Research Institute - Research Assistant - 2006.
Sort, process and identify benthic samples, including data capture and maintain a benthic reference collection database.

Oceanographic Research Institute - MSc Fellowship - 2004 - 2005.
In addition to completing an MSc, maintain the ORI research aquarium, capture data for the east coast reef survey project and assist with oyster, crayfish and mud prawn surveys.

IUCN Shark Specialist Group - Workshop assistant
Batoid Workshop - September 2003.
Sub-Equatorial Africa Workshop - September 2004.
General and administrative assistance for the duration of the workshop, and aid in documenting elasmobranches for IUCN red data list criteria.

KENDYL ANDREA WRIGHT

SYNOPSIS

Kendyl is a well-rounded scientist with experience in both the academic and applied fields. She completed her master's in environmental consultancy at the University of Plymouth in 2011, before returning to South Africa. With 10 years of professional work experience including the commercial, academic, governmental, and scientific sectors, she specialises in both estuarine and offshore macrobenthic research on the KwaZulu-Natal coastline. Kendyl has managed several different environmental projects including environmental authorizations, environmental management programme development, ecological assessments and undertaking stakeholder engagement. She has completed a PhD in macrobenthic research at the University of KwaZulu-Natal, undertaking a thesis to identify the connections between coral reefs and the adjacent sandy benthos. A competent passionate ocean enthusiast, she has experience diving (rescue diver), power boating (category C <10m), sailing and surfing.

Selected Project Related Experience

Marine

2014-2019: Identification of macrozoobenthic zonation and ecosystem linkages in the iSimangaliso Wetland Park

Kendyl spent a year sampling the nearshore macrobenthos inshore of 2-Mile Reef in Sodwana Bay, KwaZulu-Natal. An area that is not well studied, she hoped to provide improved insight into biodiversity in the region. She is currently compiling two scientific papers for publication from her doctoral thesis, allowing for improved management in the region.

2016: KwaZulu-Natal Environmental Outlook Report – Marine Specialist Component

In order to align with government legislation, a specialist report assessing the current state and pressures experienced by the KZN coastal environment was compiled. Indicators to assess the impact of these pressures were outlined for monitoring purposes. The specialist report provided improved decision-making capabilities at all levels of government.

2013-2014: Richards Bay Oil Spill and Subsequent Mangrove Monitoring, Contractual Consultant

Following a crude oil spill within Richards Bay harbour, assistance and advice were sought for the implementation of a clean-up strategy and a monitoring plan. Kendyl spent time in the field, assisting in the management of staff tasked with the clean-up. She also undertook the post-clean-up monitoring of the mangroves.

2015: Mhlanga Estuarine Assessment, KwaZulu-Natal, Contractual Consultant Anchor Environmental:

An estuarine assessment was undertaken for a Water Use License Application to permit discharge from a Waste Water Treatment Facility. Kendyl undertook the identification of the invertebrates and compiled the specialist report.

Basic Assessment

2013 – 2014: Ecocycle Waste Solutions (Pty) Ltd, Facility Expansion, KwaZulu-Natal, Consultant:

Basic Assessment for the expansion of the current Ecocycle Health Care Risk Waste Facility including stakeholder engagement, environmental assessment and report development.

2013 – 2014: Lanxess Isithebe Decommissioning, Consultant:

Waste management license and basic assessment process application to facilitate the decommissioning and decontamination of the Lanxess, Isithebe inorganic chemical manufacturing facility.

2013 - 2014: eThekwini Municipality, Mtunzi Reservoir Inlet Pipeline, Consultant:

Basic Assessment for the installation of 3 km of pipeline and associated reservoir inlet pipeline.

2012 – 2013: Transnet National Ports Authority Waste Compaction Facility, KwaZulu-Natal, Consultant:

Basic assessment and waste management license for the construction of a hazardous galley waste handling and compaction facility within the Port of Durban.

KENDYL ANDREA WRIGHT

2011 - eThekwini Water & Sanitation, Veary Road Sewer Extension, Kingsburgh, KwaZulu-Natal, South Africa, Assistant Consultant:

Basic assessment for the proposed sewer extension in Kingsburgh, Durban. Assisting in the stakeholder engagement, environmental assessment and report development.

2011 - On-going: L. Tovl & Associates CC, Dukuduku Bulk Water Supply, Mtubatuba, KwaZulu-Natal, South Africa, Assistant Consultant:

Basic Assessment for the proposed construction of a water reservoir and bulk water supply pipeline in the area of Mtubatuba, KwaZulu-Natal. Assistant consultant in preparing the amended EMPr for submission to the Department of Environmental Affairs.

Environmental Impact Assessment

2013 – 2014: Proposed Pemba Port and Logistics Base, Assistant Consultant:

Scoping and EIA for the development and construction of a new Port based in Pemba, northern Mozambique.

2013 – 2014: BrightSource Kathari Solar Energy Power Project, Assistant Consultant:

Scoping and Environmental Impact Assessment for the installation of a Solar Power Plant in Upington, Northern Cape.

2012 - 2014: Illovo Sugar South Africa (Pty) ltd, Proposed Green Boiler Project, Assistant Consultant:

Scoping and environmental impact assessment for the construction of boilers at Eston and Noodsberg to convert bagasse to energy for export to the national grid. Assistant consultant in stakeholder engagement and report writing.

Rehabilitation Plans

2013 - 2013: Stefanutti Stocks (Pty) Ltd, Umbilo Canal Rehabilitation Plan, Cato Manor, Durban, KwaZulu-Natal, South Africa, Environmental Consultant Officer:

Rehabilitation Plan for the Umbilo Canal, adjacent to the Golden Gate School in Cato Manor, Durban. Compilation of the addendum to the rehabilitation plan including the need for Dwarf Chameleon monitoring and management as well as undertaking the roe of Environmental Control Officer.

Environmental Screenings

2012 – Africa Sun Oil, Environmental Screening of a Proposed Shopping Centre, Reservoir Hills, Consultant:

Environmental Screening of the proposed new Reservoir Hills Shopping Centre based on virgin land, including the identification of potential impacts or areas of concern.

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMIRE/PASA
accepted reason. Activities associated with the Project could further pressure this species by physically harming individual seals, and by disrupting the seals' food supply. 84. The Pisces Report states that Cape fur seals are unlikely to be found in the project area, citing map that shows generalized foraging areas that extend nearly exactly to the edge of the reconnaissance area.[90] However, the report also states, "[s]eals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles (~220 km) offshore,"[91] meaning a large part of the reconnaissance area is well within the foraging range of Cape fur seals. Moreover, the Based on the questionable assumption that Cape fur seals are unlikely to occur within the reconnaissance area, the Pisces Report authors deemed their sensitivity to the proposed seismic operations to be "LOW," in spite of the finding that "The potential impact of physiological injury to seals as a result of seismic noise is deemed to be of HIGH intensity."[92] **Whales and dolphins** 85. There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.[93] 86. The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the	were more associated with operational dynamics of the Namibian fleets and their licensing conditions that had reduced their effort (as South African vessels were not permitted to fish in Namibian waters). Cumulative impacts are assessed in Section 9 of the BA report. For both technical and commercial reasons, it is unlikely that concurrent seismic surveys will be undertaken in the same area during the same survey window. However, the cumulative impacts associated with multiple surveys was assessed and detailed in Section 9.3.5 of the BAR. Section 9.3.5 of the BA Report states that "three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. This relates to the large pelagic long-line sector only, and only in the event that all three surveys are undertaken simultaneously. It should be noted that the seismic industry typically avoids simultaneous surveys occurring in close proximity to each other as this has the potential to degrade the quality of the recorded survey data. Other cumulative impacts are all expected to be low after mitigation is applied – therefore overall cumulative impacts are considered low post-mitigation. It should also be noted that of the three potential surveys cited by the Appellants, the GX Technologies survey should be disregarded as the company went into liquidation in 2022. The appellants' contention that up to 30% of the revenue generated by the impacted fisheries would be lost during the 70 day period is unsubstantiated and vague for the following reasons:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.[94] Fish 87. The BAR downplays the impacts of seismic surveys on fish and the fisheries they support, particularly in the case of the large pelagic longline fishery and the tuna pole-line fishery. While the BAR assesses the exclusion of fishing vessels due to temporary safety zones during seismic surveys, it fails to adequately assess the actual impacts of seismic activities on the target fish species themselves, both in the short and long-term. During the seismic survey, fishing vessels would be required to maintain a safe operational distance from the survey vessel and streamer array, which may extend up to 6 nautical miles. The FBAR assessed the impact of potential exclusion for each commercial sector based on the affected area of fishing ground and the amount of catch reported within the Reconnaissance Permit area. Given the location of the Reconnaissance Permit application area, two high-value fisheries are directly impacted: the large pelagic longline fishery (targeting tuna, swordfish and shark) and the tuna pole-line fishery. 88. The FBAR concluded that the Project's activities will result in exclusion to fishing grounds for at least the large pelagic longline fishery. The FBAR states that "[t]here is a high probability that the large pelagic longline sector (targeting tuna, swordfish and shark) will experience loss of access to fishing ground over the duration of the	• The four-month window is proposed to coincide with the period of lowest activities for the fisheries that operate in the potentially affected sectors, • It should further be noted that the survey will not be undertaken over the entire tuna fisheries area or the whole application area at the same time and will thus not lead to a complete shutdown of the fishing activities in the pelagic longline sector during the 70 day period of the survey; and • The mitigation measures included in Section 9.3.2 of the BAR provide for avoidance of the peak fishing periods and, furthermore, for the establishment of clear communication channels to be established with the other users of the survey area and to ensure that the disturbance within this sector is reduced to the absolute minimum. The impact on the affected fishing sectors was assessed to be of low significance and short duration and it could thus not be stated that "The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna." Impacts of cumulative sound exposure on marine mammals are evaluated using disturbance and injury threshold, defined as temporary threshold shifts (TTS) and permanent threshold shifts (PTS) (Southall et al. 2019). The audibility of a noise pertains only to the perception or detection of a sound above background levels of ambient noise. The thresholds established by Southall et al. (2019) are internationally regarded as standard references for environmental impact assessment of underwater noise. Although the modeling report doesn't specifically reference the CBA areas, the purpose of the modelling was to model the likely sound transmission and contours. The outputs of the model were then

1 OVERVIEW

This document provides commentary and expert opinion on the scientific soundness of activities related to a planned seismic campaign in the Orange Basin region off the west coast of South Africa. Specifically, it examines whether Appendix 3.5 – "TGS: SOUTH AFRICA ORANGE BASIN 3D SEISMIC SURVEY SOUND TRANSMISSION LOSS MODELLING" (hereafter referred to as the "Acoustics Specialist Report") and Appendix 3.1 –"PROPOSED 3D SEISMIC SURVEY IN THE ORANGE BASIN OFF THE WEST COAST OF SOUTH AFRICA: BIODIVERSITY AND ECOSYSTEM SERVICES ASSESSMENT" (hereafter referred to as the "Marine Ecology Report")—both in support of the document "ENVIRONMENTAL BASIC ASSESSMENT REPORT: PROPOSED TGS ORANGE BASIN RECONNAISSANCE PERMIT, PASA REFERENCE: 12/1/040" (BAR)—adequately assess the environmental impact of anthropogenic noise associated with seismic operations and related maritime activities. This document includes commentary on the appropriateness of the content in the Acoustic Specialist Report and the Marine Ecology Report for developing mitigation strategies outlined in Section 9 ("Environmental Impacts Assessment," EIA) within the BAR, and the suitability of the proposed mitigation strategies in addressing potential harms related to sound produced by the proposed seismic operations.

1.1 PROJECT DESCRIPTION

TGS Geophysical Company (UK) Ltd is planning a seismic campaign in the Orange Basin off of the west coast of South Africa, pending the approval of the Reconnaissance Permit and vessel availability (the "project"). The Reconnaissance Permit Area spans approximately 57,400 km², located about 120 km offshore from St Helena Bay, extending to around 230 km offshore from Hondeklip Bay across several petroleum license blocks.

The survey will utilize a single 100 m seismic ship equipped with seismic sources and streamers, supported by up to two escort vessels of unknown size, and is expected to last around 70 days. The towed hydrophone streamers would be 8,000 meters in length and 2,000 meters, approximately the area of 3,000 football fields. The seismic pulse would be discharged every 2-6 seconds continuously during exploration operations at source levels (loudness at the source) between 200-255 dB re 1 µPa; for reference this is among the loudest produced anthropogenic sounds on the planet and is in the range of military weapons or explosions.

1.2 SUMMARY OF OPINION

The Acoustics Specialist Report and the associated Marine Ecology Report solicited by TGS fail to adequately demonstrate that anthropogenic noise generated by the proposed seismic campaign will not have significant ecological consequences for marine organisms and habitats at the permit location. This is primarily due to (1) the failure to recognize the anthropogenic noise from the project as chronic, (2) the failure to consider the full spatial extent of the noise generated by the project, (3) the omission of an assessment of underwater ambient sound conditions at the site prior to the proposed activities, (4) the failure to evaluate potential impacts on the broader marine community, including population-level effects, and (5) the failure to incorporate the most up-to-date and relevant scientific recommendations for assessing industrial noise impacts on marine ecosystems.

Consequently, the mitigation actions proposed in the associated Environmental Impact Assessment (EIA) are based on an inaccurate assessment of noise impacts and fail to meaningfully address the potential or likely impacts of anthropogenic noise on the marine environment related to the seismic exploration. Moreover, the mitigation actions proposed in the EIA fail to address the full range information contained in the specialist reports and reiterated within the text of the EIA, this willful omission results in even less comprehensive or appropriate mitigation measures.

1.3 PRIMARY FAILURES OF THE BAR and ASSOCIATED SPECIALIST REPORTS

1. Inadequate Premise and Limited Scope of Impact
   The Acoustics Specialist Report is founded on a flawed temporal premise and exhibits a narrow scope that fails to comprehensively address the complexities of anthropogenic noise impacts on the environment. As the primary resource used to assess mitigation needs associated with anthropogenic sound, the report is severely lacking. The fault of this should be attributed to TGS- who commissioned the report and determined the scope assigned to the contracting agency.

2. Appropriateness of Inference in Marine Ecology Report
The Marine Ecology Report uses the outputs of the Acoustics Specialists Report in concert with data from a desk study to assess acoustic impacts on the marine environment; as such it contains the same flaws as the Acoustics Specialist Report and additionally underestimates the severity of seismic survey noise impacts. The report suggests insufficient mitigation strategies that fail to consider population-level impacts, soundscape level impacts, or chronic impacts associated seismic operations.

3. Insufficient Mitigation Measures within the EIA
The proposed mitigation measures do not adequately address the potential acoustic impacts of the proposed project on the marine ecosystem, leaving significant risks unmitigated. The best available science was not considered when assessing the impact of the project, the scope of the available information was overly narrow, and the EIA selectively omits information included in the specialist reports and the broader literature.

2 GENERAL INTRODUCTION TO ANTHROPOGENIC NOISE IN THE MARINE ENVIRONMENT

Anthropogenic noise refers to sound generated by human activities, including infrasonic (below the range of human hearing) and ultrasonic vibrations (above the range of human hearing), as well as sounds within the human audible range. Anthropogenic noise poses a significant threat to organisms that rely on sound for vital life functions such as foraging, breeding, migration, and social interaction. Its effects are particularly severe in marine ecosystems, where sound travels vast distances with minimal energy loss. Most marine species have evolved to depend on sound as their primary sensory modality.

Social cetaceans and seabirds, including whales, dolphins, and penguins, rely on acoustic signals for communication, foraging, and social cohesion. Bottom-dwelling animals, fish, and invertebrates also respond to environmental sounds; for example, larval stages of various species use sound cues to time their transition from open water to benthic habitats. Alterations to the marine soundscape impact how marine animals interact with their environment, have the potential for both short term individual harm, and may result in shifts in long-term population dynamics.

Anthropogenic noise impacts ecosystems by disrupting communication, displacing species from critical habitats, altering foraging and predator-prey behaviors, increasing physiological stress, causing physical harm (including hearing loss), and even leading to mortality. Assessing these effects requires an interdisciplinary approach, combining ecology, resource management, acoustics, and statistics. Research on marine responses to noise has documented behavioral changes, auditory impairments, increased mortality, and reduced reproductive success. As such, any activity that generates noise may have significant ecological consequences, underscoring the need for comprehensive environmental impact assessments.

2.1 RELEVANT DEFINITIONS AND EXPLANATIONS

Characterizing Sounds

When determining the impacts of noise on an organism or an ecosystem, the sound must first be characterized. Sound is broadly characterized according to the following:

1. Duration: how long each signal lasts
2. Frequency (or pitch): how high, low, or broadband (simultaneously high and low) a sound is
3. Pulsivity: whether a sound is impulsive (like a series of bangs from fireworks) or continuous (like traffic noise)
4. Chronic versus discrete: Does the noise occur in a single short time period (like a jackhammer outside of an apartment window for a morning) or does it persist over long time periods (like an apartment which abuts a train track with trains passing by every day for many years).

Inappropriately characterizing noise has severe implications on individuals or organisms, and improper characterization can hide ecological impacts that may be significant. For example:

1. Duration: It would be misleading to characterizing the duration of a fireworks display that took place from 7pm until 11pm as having an average duration of 1.4 seconds (the length of time of a single firework).
2. Frequency: It would be misleading to say that simultaneously blowing 10,000 dog whistles (which are too high pitched for humans hear) would not impact a mother dog and her pups that were feeding 1 meter from the whistle blowers, simply because it doesn't substantially contribute to overall low frequency sound levels.
3. Pulsivity: It would be misleading to say that animals were capable of adjusting the timing of their calls to vocalize in between sound signals, if the sounds were continuous and there was no break between sounds.
4. Chronic vs. discrete: It would be misleading to say that the sound of a jackhammer outside of a bedroom window would have negligible effects on the apartment residents because it only occurred for three hours, when in reality the sound of the jackhammer occurred for three hours every day at 3am for 20 years.

Determining Ecological Baselines

To assess whether elevated noise levels associated planned human activities will impact an ecosystem, it is crucial to understand the environment's sound profile prior to the proposed human interference. This process is referred to as "determining the baseline soundscape," defined as the acoustic condition of a site before anthropogenic disturbance.

Components of a Baseline Soundscape Assessment: A baseline soundscape assessment should provide a thorough analysis of the sonic environment prior to proposed anthropogenic activities, focusing on spatial and temporal variations in sound levels and frequencies. Key components include:

1. **Identification and Characterization of Natural Sound Sources:** This includes biophony (sounds from living organisms), geophony (natural environmental sounds), and anthrophony (human-generated sounds).

2. **Data Collection Across Habitats and Seasons**: The assessment should capture sound data across different habitats and seasonal variations within a proposed site, enabling the detection of changes in sonic diversity and diel sound patterns associated with alteration.
3. **Evaluation of Sound Pressure Levels**: This includes assessing sound levels across ecologically relevant frequency ranges and identifying key signals, correlating these findings with ecological functions.
4. **Establishment of Reference Points for Ambient Noise Levels**: Identifying pre-project sound levels and sources is essential for future impact assessments and for effective project management and harm prevention. In the absence of pre-project sound levels, contributions of the project to the soundscape cannot be assessed, and preventative mitigation cannot be employed.

Mischaracterization or omission of baseline soundscape elements can significantly impact ecological interpretation, leading to negative ecological consequences across several scales. For example:

1. **Erroneously Assigning Acoustic Baselines**: An urban task force tasked with determining whether traffic noise affects the foraging habitat of a rare bird compares ambient noise levels during moderate traffic and a period with a single tractor-trailer truck. They conclude noise has no impact based on equivalent noise levels. However, a second task force compares recordings from a traffic-free Sunday morning and a Monday rush hour, revealing a 300% increase in ambient noise due to traffic—an important change that would be overlooked with a mischaracterized baseline.
2. **Omitting Frequency Analysis**: The same task force examines whether new power lines interfere with bat echolocation (ultrasonic frequencies >20 kHz). They report a small increase in average sound levels between 1 kHz and 30 kHz, concluding the noise increase is not ecologically significant. However, noise levels in the bats' communication range exceed 400% when power lines are active, indicating that their findings could lead to hearing loss in bats.
3. **Omitting Temporal Patterns of Sound Sources**: A contractor records baseline sounds for only 10 seconds each hour over a single autumn day, outside the typical mating and migration seasons. Consequently, the report lacks data on these critical signals and inaccurately concludes that elevated noise levels won't impact them. In reality, migrating and mating animals acoustically present for several months each year were simply not recorded.

3 SPECIFIC COMMENT AND CRITIQUE OF SPECIALIST REPORTS

3.1 INADEQUATE PREMISE AND LIMITED SCOPE OF ACOUSTICS SPECIALIST REPORT

3.1.1 Appendix 3.5 – "TGS: South Africa Orange Basin 3D Seismic Survey Sound Transmission Loss Modelling" (Acoustics Specialist Report), prepared by Environmental Impact Management Services Inc. (EIMS), presents a Sound Transmission Loss

Modeling (STLM) study to assess the spatial extent of noise impact on marine fauna within the proposed survey area off the West and South-West Coast of South Africa. This report was commissioned by TGS and used as the basis for risk assessment and mitigation planning associated with the proposed project.

3.1.2 The science contained within the report appears to be thorough. Due to fundamental flaws in its initial assumptions and the project scope requested by TGS, however, the Acoustics Specialist Report fails to accurately represent the real-world impacts of 3D seismic exploration on the marine soundscape and marine organisms within and beyond the proposed permit area. The report is based on incorrect premises regarding both the temporal and acoustic characteristics of the noise. EIMS' study focuses on the impact of discrete, 24-hour, pulsive noise on low-frequency sound levels in an otherwise pristine marine environment. Specifically, EIMS was tasked with identifying zones of impact from single airgun pulses and the cumulative effects of multiple airgun pulses over a 24-hour period (Acoustics Specialist Report, p. i).

3.1.3 In reality, the proposed project involves chronic pulsive noise coupled with continuous vessel noise over several months (70 days), significantly raising ambient sound levels in the low and mid-frequency ranges that affect marine mammals, fish, and invertebrates, both within and beyond the proposed project area. If the project were limited to 24 hours and only involved airguns, the study's assumptions might be valid. However, the cumulative effects of sustained high-intensity noise from multiple sources over 70 days are far more impactful than the short-term effects modeled in the report.

3.1.4 The Acoustics Specialist Report's failure to consider the added impacts of multiple sound sources on both direct (injury) and indirect (behavioral) effects on animals significantly undermines the assessment and its use for determining robust mitigation plans. The study exclusively considers the threats posed by airguns, primarily modeling the temporary threshold shifts (temporary deafness, TTS) and permanent threshold shifts (permanent deafness, PTS) associated with their use, with moderate to minimal consideration for behavioral impacts. However, additional sound sources—including two support vessels, a seismic ship measuring 100 meters in length, and generator noise on the ship—are also critical sources of noise associated with the proposed project. Recent research investigating marine mammal response to noise associated with seismic operations indicates that the behavioral response to seismic vessels is at the same magnitude as the airguns themselves[1] Notably, while airgun noise is generally considered low-frequency (<200 Hz), the frequency range produced by vessels is broader (also including mid-high frequency components), which were not included in the noise impact assessment. Noise from these additional omitted sources contributes to the overall ambient sound levels, collectively affecting the acoustic environment that marine organisms rely on for survival.

3.1.5 No baseline soundscape assessments were made for the proposed permit region within the Acoustics Specialist Report nor the BAR. No effort was made to quantify the naturally occurring sound levels for this region, the sources of naturally occurring sounds, or the seasonal and temporal cycles in ambient sound levels that may serve as

228

ecologically important cues. Given that marine organisms use sound for navigation, prey detection, predator avoidance, and foraging, alterations to the natural soundscape within and beyond the permitted region may have severe ecological consequences. In the absence of known natural ambient noise levels, it is not possible to assess how much the proposed activities will increase ambient noise levels in the soundscape—and therefore also not possible to assess underwater noise impacts.

3.1.6 The contribution of this project to the ambient soundscape is particularly relevant given that airguns produce some of the loudest known underwater sounds on the planet[2,3] and in some cases, can be detected 4,000 kilometers from the source[4]. The Acoustics Specialist Report failed to quantify how many total square meters would be ensonified as a result of the proposed project (see Wood 2010 for an example)[4]. However, based on the modeling reported, the detection of airguns is certain to expand beyond the permitted area and into the Critical Biodiversity Areas (CBA) and Marine Protected Areas (MPA) within and beyond the permitted area (Acoustics Specialist Report, Figure 17; Marine Ecology Report, Figure 42). Additionally, seismic and support vessels will operate beyond the limits of the proposed permit region, transiting through both CBAs and MPAs. The contributions of these sound sources to sensitive habitats were not modeled or addressed. Soundscape impacts and ensonification ranges were not solicited by TGS, and would have indicated a much broader spatial impact of the project than is currently reported.

3.1.7 Noise produced from industrial activities cannot be physically contained underwater and may inundate critical biodiversity locations proximate to proposed operations and associated vessel activities. This requires careful consideration given the known impact of noise on marine mammals (stress, behavioral responses, reduction in foraging[5]), fish (behavioral responses, physiological responses, antipredator responses, death[7,8]), larval invertebrates (reduction in settlement, larval deformation [9–11]), and pelagic zooplankton (death[12]). Anthropogenic noise within CBAs and MPAs may harm, alter, or lead to death or population decline across a wide range of organisms and life stages that make up both ends of the trophic web. Because noise cannot be contained to the project site due, the impacts of noise are further reaching than the directing region of interest and must include coastal and adjacent pelagic areas as well.

3.1.8 An adequate baseline assessment of the acoustic properties of the soundscape—including biological sources of ambient sound, environmental sources, and ambient sound levels—is needed to complete an assessment of underwater noise impacts. Broader-scale sound propagation modeling, including the total range of ensonification associated with airguns and general project operations (seismic ship returning to port, support vessels, aircraft), throughout both pelagic and coastal habitats – inclusing seismic ship travel routes – is essential for adequately assessing project impact, risk, and mitigation strategies. This is particularly relevant for the Child's Bank, the Tripp Seamount, Cape Canyon and Cape Valley, which will likely experience changes in ambient soundscape conditions associated with the project. The report models ensonification up to 200 km, and notably the project is associated with high noise values up to that range (e.g., Acoustics Specialist Report, Figure 17).

8428

3.1.9 The Acoustics Specialist Report overlooks the broader ecosystem-scale consequences of injuries caused by anthropogenic noise. The report focuses primarily on direct physical injuries to marine organisms, such as hearing damage from airgun blasts. This is not a comprehensive assessment. Temporary or permanent hearing loss, stress, and direct or indirect death in fishes and invertebrates are all physical consequences of anthropogenic noise exposure. However, the repercussions of such injuries extend beyond individual organisms and can affect entire ecosystems. When marine mammals or fish experience hearing loss, their ability to communicate, navigate, and locate predators or prey is compromised. This impacts their survival and can also disrupt predator-prey dynamics within the ecosystem, leading to population imbalances. Additionally, both injuries and anthropogenic noise in isolation can lead to stress responses in affected species, potentially resulting in altered reproductive success and decreased population resilience. The failure to adequately assess these ecosystem-level consequences limits the understanding of how noise pollution can disrupt ecological interactions and degrade marine biodiversity.

3.1.10 In addition to the direct impacts on individual animals, the report fails to consider the population-level consequences of behavioral changes induced by noise exposure. Noise from airgun activities can lead to significant shifts in the behavior of marine species. Responses of fishes to anthropogenic noise include reduction of anti-predator response, which leave individuals at higher risk of being eaten, acoustic masking of breeding sounds which may impact species at the population level, and reduced breeding success [6,13,14].Marine mammals may alter their vocalization patterns, leading to reduced communication effectiveness. Fish may also exhibit changes in schooling behavior or abandon critical habitats due to increased noise levels. Such behavioral changes can affect reproduction rates, survival, and population dynamics over time. Furthermore, if key species alter their foraging behaviors or habitats, the repercussions can cascade through the food web, impacting other species reliant on them. The Acoustics Specialist Report's neglect of the consequences of behavioral shifts and their population-level impacts undermines the comprehensive assessment needed to understand the full ramifications of the proposed project on marine ecosystems.

3.1.11 The report also fails to quantify the number of marine animals likely to be acoustically impacted by airgun and other anthropogenic noise sources, missing an opportunity to address critical factors such as sex and behavioral state that influence vulnerability to noise exposure. Research indicates that certain demographics, such as nursing females, may be more sensitive to noise due to their specific behavioral contexts [15]. To fully understand the implications of noise exposure, it is essential to estimate the proportion of populations that could be affected by the proposed activities, particularly for vulnerable species. Furthermore, long-term consequences for impacted individuals can include decreased reproductive success and altered migration patterns[16,17], which can lead to population declines over time. A robust assessment would not only quantify the number of individuals affected but also evaluate the potential implications for population viability, particularly in the context of ongoing anthropogenic pressures[18]. This level of analysis is critical for informing appropriate mitigation strategies and ensuring the long-term sustainability of marine populations.

8228

3.1.12 Since the release of the Acoustics Specialist Report, more recent scientific studies have emerged that challenge the premise of using blanket sound exposure level (SEL) or sound pressure level (SPL) thresholds to assess the impacts of anthropogenic sound on marine animals (Southall 2024). The Acoustics Specialist Report heavily relies on Southall (2019) to justify using these thresholds to determine varying levels of risk, while omitting the caveats included in the 2019 publication. Southall 2019 states that "***The approaches [in Southall (2019)] are not applicable to evaluating potential auditory effects of chronic noise exposure over periods of weeks, months, or years.***" [19]

3.1.13 In the updated guidelines, Southall (2024) again explicitly states that "simplistic received level-only step-function 'thresholds' indicating a binary lack or presence of response for any sound type are outdated and inconsistent with the best scientific information available"[18]. The Acoustics Specialist Report relies on exactly these binary thresholds, despite strong scientific evidence that this method is flawed[18,19]. Moreover, Southall (2024) highlights the issue of appropriately assessing the temporal scale (chronic impacts versus acute impacts) as a major flaw in the method used in the Acoustics Specialist Report. According to Southall (2024), "Where the acute exposure-response severity scale-based assessment approach really falls short is in the evaluation of repeated or sustained exposures for aggregations and/or local populations of animals on broader spatial and temporal scales." Given the multiple months of sound exposure to this ecosystem (70 days), this should be considered a chronic rather than acute sound source.

3.1.14 Beyond the 2024 publication, which the agency responsible for the Acoustics Specialist Report may not have had access to, Southall (2021) offers clear recommendations on acoustic exposure and the types and severity of behavioral responses, focusing on vital rates during acute events. Notably, Southall (2021) was not cited in the Acoustics Specialist Report, despite the report's goal of determining zones of impact for behavioral responses Acoustics Specialist Report, p. i). Given the Acoustics Specialist Report's reliance on Southall (2019), it should be assumed that the work of Southall—internationally regarded as industry standard and best practice—is considered reliable by BIMS. The omission of the most recent work is yet another indication that the Acoustics Specialist Report fails to reach the necessary depth to be used for reliable environmental impact assessment. These flaws can be predominantly associated with the scope of the project as requested by TGS.

Summary of Comments on Acoustic Specialist Report:

1. **Inaccurate Assumptions in Acoustic Specialist Report:** The report is based on incorrect assumptions, primarily focusing on short-term impacts from 24-hour airgun pulses. However, the actual project will involve 70 days of chronic, high-intensity noise, including both airguns and continuous vessel noise, leading to significantly higher impacts than modeled.
2. **Underestimated Noise Sources:** The study overlooks the noise contributions from multiple sources, including support vessels and generator noise, which affect both low and mid-frequency ranges critical to marine fauna and elicit behavioral responses. These omitted noise sources exacerbate the overall impact of seismic operations on the marine soundscape.

3. **Lack of Baseline Soundscape Assessment:** No baseline data on natural ambient noise levels or soundscape characteristics in the project area were collected, making it impossible to accurately assess how much the proposed activities would increase ambient noise levels.
4. **Broader Spatial Impact Unaccounted For:** The report fails to quantify how far noise will travel beyond the project area, particularly into Critical Biodiversity Areas (CBAs) and Marine Protected Areas (MPAs), where noise could have far-reaching ecological consequences.
5. **Insufficient Consideration of Ecosystem-Level Consequences:** The report focuses primarily on direct physical injuries (such as hearing loss) but does not adequately address the indirect effects on behavior, communication, and predator-prey dynamics, which could disrupt entire ecosystems.
6. **Failure to Address Behavioral and Population-Level Impacts:** Noise-induced behavioral changes, such as altered communication or abandonment of critical habitats, are not properly assessed. These changes could lead to population-level consequences, affecting reproduction, survival, and overall ecosystem stability.
7. **Outdated Noise Thresholds and Methodologies:** The report relies on outdated sound exposure thresholds that fail to account for the chronic nature of the project's noise impacts. More recent scientific guidelines suggest that this approach is insufficient for assessing long-term impacts on marine animals.
8. **Missing Quantification of Impacted Marine Animals:** The report does not estimate the number of marine animals likely to be affected by the noise, nor does it consider the heightened vulnerability of specific demographics, such as breeding males or nursing females, to noise exposure.
9. **Need for Scaled Sound Propagation Modeling:** The report requires a broader-scale sound propagation model and an assessment of the full spatial and temporal extent ensonification.

3.2 COMMENTS ON APPROPRIATENESS OF INFERENCE IN MARINE ECOLOGY REPORT

3.2.1 Appendix 3.1 – " PROPOSED 3D SEISMIC SURVEY IN THE ORANGE BASIN OFF THE WEST COAST OF SOUTH AFRICA: Biodiversity and Ecosystem Services Assessment " (Marine Ecology Report), builds on the information provided in the Acoustics Specialist Report. As such, it shares same shortcomings, as well as additional issues with scope, depth, and inappropriate inference of acoustic information and application to mitigation strategies.

3.2.2 The Marine Ecology Report mirrors the shortcomings of the Acoustics Specialist Report by considering TTS an acceptable impact after mitigation, despite significant unknowns regarding the consequences of temporary hearing loss for affected populations and species. The Marine Ecology Report fails to account for the potential impacts of repeated noise exposure over multiple days, which could have more serious long-term effects that those assumed in the report. Established methodologies, such as those from Wood (2010) and Southall (2024), provide

guidance on assessing environmental impacts based on sex and behavioral states. However, the Marine Ecology Report neglects to incorporate these variables or critically to estimate the total proportion of marine populations of any species likely to be affected by the 70-day project. This omission occurs, despite the acknowledgement that portions of the proposed permit area are ecologically valuable for critical species and are in some cases considered vulnerable to human activities (Marine Ecology Report, "3.4.2 Conservation Areas and Marine Protected Areas"). Instead, the report applies the same simplistic binary threshold approach as the Acoustics Specialist Report, without considering chronic impacts or population level consequences.

3.2.3 In the case of marine mammals, prolonged exposure to noise is associated with chronic stress, internal and external injuries, displacement from breeding and foraging areas, altered migratory patterns, and permanent hearing loss [17,20–23]. Despite the vulnerability of local cetacean species such as humpback whales, sperm whales, Bryde's whales, and beaked whales found in the proposed permit area (Marine Ecology Report, Table 7) neither the Marine Ecology Report nor the Acoustics Specialist Report adequately addresses the risks associated with chronic noise exposure for these animals at the individual or population level. The assumption was made that animals would likely leave the area, but there was no quantitative estimation of the number of individuals impacted, the probability of habitat abandonment, the change in probability associated with age, sex, or behavior state (e.g. cows and calves versus adult males). This is particularly critical for data deficient species (fish, invertebrates, benthic organisms in abyssal regions) and deep diving odontocetes expected to use much of proposed region.

3.2.4 The Marine Ecology Report and associated EIA recommendations (BAR Section 9: Environmental Impact Assessment) fail to adequately suggest mitigation measures that will address the acute risks of seismic operations to the marine environment. The proposed measures, including a 500 m buffer around sensitive areas, a 500 m mitigation zone, Marine Mammal Observers (MMO), Passive Acoustic Monitoring (PAM), and operational responses based on animal proximity, are inadequate. For example, the report acknowledges that certain species, including beaked whales, are at risk of fatal acoustically induced decompression sickness —a behavioral response with an acute outcome (Marine Ecology Report, p. 67). Very high frequency cetaceans, which includes most odontocetes and beaked whales and will be impacted at ranges of 650 m (injury) and 3.8 km (behavioral responses), yet the mitigation zone is only 500 m. This is a clear misalignment between the proposed mitigation strategies and the data driven spatial extent of impact to marine species. Per the information included in the Marine Ecology Report, this misalignment may result in odontocete fatality.

3.2.5 Similarly, the Marine Ecology Report downplays the impact of noise on invertebrates and prey species, and the report suggests ineffective mitigation strategies to minimize the impact of seismic operations. While the report acknowledges the physiological and behavioral responses of squid (Marine Ecology Report, "4.3.6 Impacts of Seismic Noise

on Marine Invertebrates")— a primary prey source for marine mammals, including beaked whales, in Southeast African waters [24,25]—it incorrectly downplays squid mortality as having a LOW impact due to temporal and spatial scale. The report claims the impact on squid would be REGIONAL and IMMEDIATE- 1.5 months, but mortality is permanent and behavioral responses of surviving squid will likely occur beyond the permitted region, as the acoustic influence zone (2–5 km) extends beyond the survey area during operations (EIA, p. 215, area (Acoustics Specialist Report, Figure 17; Marine Ecology Report, Figure 42). The loss of squid would significantly affect trophic interactions, especially in a system already low in food sources. The report's claim that the removal of squid (a scarce resource) is low impact, is akin to draining a desert oasis and labeling the impact low because water is rare there anyway.

3.2.6 Additionally, the proposed mitigation measure intended to minimize harm to cephalopods —"Terminate seismic shooting upon observing any obvious mass squid mortalities estimated by the MMO as a direct result of the survey"—is ecologically unsound. Squid, which are found at depth, are neutrally or negatively buoyant and will not float to the surface for meaningful observation [26]. Even if they did float to the surface, they are highly camouflaged and ship movement would scatter them, making detection by the MMO virtually impossible. This suggestion that MMO's would be capable of reporting squid mortality is unrealistic, and the consequences of squid mortality are ecologically meaningful.

3.2.7 Impacts to Plankton and Ichthyoplankton were considered MEDIUM before mitigation, and LOW after mitigation. However, the proposed mitigation measures – for example no seismic operation within 5 km of important ecological areas – directly minimize the duration or extent of high source level sounds inundating the marine soundscape (see Figure 45a, Marine Ecology Report for a visualization of spatial scale, see also Madsen et al 2006)[17]. Noise associated with seismic operations will extend well beyond 5km, and vessel noise within ecologically vulnerable areas may have meaningful impacts that were omitted from this assessment. Fishes exposed to anthropogenic noise experience reduced anti-predator responses, leaving them more vulnerable to predation, acoustic masking of breeding sounds, reduced breeding success, temporary or permanent hearing loss, stress, and death[17,28,29]. Many larval invertebrates and fishes, such as corals, shellfish, and crustaceans, rely on sound to locate suitable habitat for settlement—the transition from their pelagic phase to a permanent location.[30–37] Acoustic masking of environmental cues within MPAs CBAs or other vulnerable habitats exposed to both seismic and vessel sounds may disrupt this process for key structure-building organisms.

3.2.8 Importantly, like the Acoustics Specialist Report, the Marine Ecology Report fails to consider population-level consequences for any species of interest. It makes no effort to quantify the number of individuals affected by the proposed activities or to assess the potential short- and long-term impacts on population dynamics. These omissions minimize the overall consequences of the proposed seismic activities. Understanding population-level impacts is critical, as disruptions to even a small number of individuals can have cascading effects on the species' reproductive success, genetic diversity, and

long-term survival, or may have meaningful trophic implication as prey species (like squid) grow scarce.

3.2.9 Lastly, the Marine Ecology Report fails to quantify soundscape properties in relation to other oceanographic features, such as bathymetry and currents. Since sound is the primary way marine organisms interact with their environment, the omission of a basic soundscape description and the potential impacts of the proposed project on it is a significant oversight.

Summary of Comments on Marine Ecology Report

1. **Inadequate Consideration of Temporary Threshold Shifts (TTS):** Based on mitigation suggestions the Marine Ecology Report TTS an acceptable post-mitigation outcome and fails to address the long-term consequences of temporary hearing loss to individuals of specific species or populations. There is also no consideration for the cumulative effects of multiple days of noise exposure. It overlooks more detailed approaches, such as assessing impacts based on species' sex and behavioral states, and neglects to estimate how much of the marine population will be affected by the 70-day project.
2. **Chronic Noise Exposure Risks:** The report downplays the significant risks of prolonged noise exposure for vulnerable cetacean species (e.g., humpback whales, sperm whales, beaked whales). It fails to assess how chronic noise might cause stress, injuries, altered migration patterns, and permanent hearing loss. There is also no quantitative estimation of how habitat alteration might affect these species.
3. **Insufficient Mitigation for Acute Noise Impacts:** The mitigation strategies proposed, including a 500 m buffer zone, are insufficient to minimize acoustic impacts to marine species (e.g, beaked whales and cephalopods). This highlights a failure to align mitigation efforts with the real world risks.
4. **Failure to Address Population-Level Impacts:** The report does not estimate how many individuals will be affected or assess the broader population-level consequences of direct or indirect harm, which downplays the long-term impacts of seismic exploration to this marine ecosystem.
5. **Omission of Soundscape Analysis:** The report neglects to assess the soundscape in relation to key oceanographic features (e.g., bathymetry, currents), despite sound being critical for marine organisms' interactions with their environment.

Overall, the report underestimates the severity of both acute and chronic noise impacts on marine life and offers inadequate mitigation strategies without accounting for population-level or soundscape effects.

3.3 INSUFFICIENT MITIGATION MEASURES PROPOSED WITHIN BAR SECTION 9 "ENVIRONMENTAL IMPACT ASSESSMENT" (EIA)

Throughout, the EIA fails to effectively propose mitigation measures that will address the acoustic impacts of seismic operations on the marine environment. Broad criticisms of the BAR's approach to mitigating acoustic impacts as well as specific criticisms on mitigation measures are below.

Broad Criticisms Associated with BAR Section 9, Environmental Impact Assessment (hereafter "EIA")

3.3.1 **Failure to Address Habitat Variability:** The BAR fails to adequately account for the variability in habitat sensitivity within the proposed permit region. The region in question displays significant bathymetric variability (BAR, p. 46), with habitat use and biodiversity differing greatly throughout the area (Marine Ecology Report, p. 19). For example, the Marine Ecology Report highlights the continental slope region (200–2000 meters in depth) as likely to support cetaceans and endangered fishes (Marine Ecology Report, Table 1 & p. 50), yet, the EIA (BAR, Section 9 "Environmental Impact Assessment") does not propose targeted mitigation measures for activities on the continental slope. Environmental mitigation measures should consider different operational behaviors based on habitats expected to harbor higher biodiversity or be home to species of concern.

Different marine habitats support distinct species assemblages, each with its own sensitivities to human-induced disturbances. The lack of appropriate mitigation in certain regions could result in physical damage to sessile organisms that inhabit specific habitats but lack the ability to abandon an environment when seismic operations commence. Alternatively, mobile organisms like cetaceans are more likely to congregate along continental slopes where nutrient upwelling attracts prey (Marine Ecology Report p. 50). Ignoring habitat-specific sensitivities increases the risk of disrupting critical ecological processes.

3.3.2 **Inconsistencies within the BAR:** The BAR and associated EIA contain inconsistencies. For example, the BAR proposes a long-term soundscape analysis for acoustics mitigation (BAR, p. 259) but fails to specifically include this measure in mitigation plans or to indicate spatial and temporal extent as part of the preventive strategies. The BAR also specifically acknowledges the need to minimize ambient sound levels associated with seismic operations (BAR, p. 245), yet requires no concrete mitigation measures regarding implementing technological or operational adjustments.

The EIA makes broad recommendations without considering the specific environmental conditions or the species most at risk at any given location or time of year. For example, seismic operations are proposed for January–May to minimize impact to baleen whales and commercially important fisheries – yet the BAR states that "it should also be kept in mind that some of the migratory species are now present year round off the West Coast, and that certain baleen and toothed whales are resident and/or show seasonality opposite to the majority of the baleen whales" (BAR, p 244). Despite this acknowledgment, these data were not meaningfully incorporated into planning or mitigation.

Effective EIAs should provide consistent, integrated, and transparent evaluations of all potential risks. A fragmented approach can result in a gross underestimation of cumulative or synergistic effects, where multiple stressors interact to amplify the harm caused.[38]

3.3.3 **Overly Optimistic Reliance on MMOs and PAM** The EIA fails to provide a clear scientifically driven, adaptive plan for real-time responses based on monitoring during the seismic survey. The existing plan incorporating real-time monitoring data (e.g., Passive Acoustic Monitoring (PAM) or Marine Mammal Observers (MMOs) is touted as a catch all to mitigate nearly every acoustic impact. MMOs, however, are limited in the scope and scale of their observations and PAM only captures loudly vocalizing animals (essentially omitting invertebrates and fish). Research indicates that the visual extent of MMOs from large ships is limited to 1 km, [5,18] yet per the Acoustics Specialist Report and the Marine Ecology Report acoustic impacts to marine mammals occur well beyond this range. MMOs are tasked with documenting mammals, fish, turtles, seabirds, fishes and invertebrates. This is both unrealistic and unreasonable. Many species of concern (e.g., odontocetes like sperm whales or beaked whales) have dive times in excess of one hour and surface intervals of less than a minute[39,40], making them hard to sight. Invertebrates, like squid, are negatively or neutrally buoyant[41] and aren't likely to be at the water's surface. Similarly, most fish species can't be reliably cited from a ship observation platform. Thus, while MMOs and PAM operators are crucial for reducing seismic operation impacts, they are not a panacea to address all potential risks.

3.3.4 **Incorrect Temporal Scale** The EIA focuses on short-term acoustic impacts (seconds to hours), despite the project involving approximately 70 days of seismic operation. This narrow focus disregards the long-term implications of chronic noise exposure. Prolonged anthropogenic[20,42,43] noise can lead to cumulative effects such as chronic stress, hearing damage, and altered behavioral patterns in marine species.[17] These chronic impacts, especially over the course of two months, are more likely to disrupt population dynamics, such as habitat avoidance or disrupted breeding patterns, which were overlooked in the assessment. Noise from the seismic survey is both chronic and spatially far-reaching, making the EIA's temporal scope inaccurate (See Commentary on Acoustics Specialist Report).

3.3.5 **Unknowns Are Disregarded** The EIA does not sufficiently account for unknown variables, including species-specific responses, role of behavioral states, lack of biodiversity data and ecosystem sensitivities. Uncertainty is inherent in ecological impact assessments, particularly when dealing with complex, dynamic marine ecosystems. It is essential to adopt the precautionary principle in such cases, ensuring that mitigation measures err on the side of caution to protect ecosystems from unforeseen consequences [18,44]. By failing to address these unknowns, the EIA underestimates in the scoring system and in its overall assessment the potential impacts of the seismic activity on species and habitats. The failure to collect baseline data significantly increases uncertainty; despite this, the EIA does not recommend commissioning ecological studies to address biological unknowns.

3.3.6 **Disregard for Far-Field Sound** The EIA does not adequately consider the effects of far-field sound, which can propagate over long distances and affect distant marine life. On page 58 of the BAR states that for areas that "receive the sound in the far field only, no detrimental effects to the communities or to individual benthic species are expected" (BAR, p. 58). However, seismic noise can travel thousands of kilometers [4], disrupting long-range communication among marine species such as cetaceans.[45] Far-field sound from seismic airguns will extend well beyond the immediate operational area, including into Critical Biodiversity Areas (CBAs) and Marine Protected Areas (MPAs) (see commentary on Acoustics Specialist Report and Marine Ecology Report), yet the EIA does not quantify the extent or ecological consequences or far field sound, nor does the EIA recommend broader scale acoustic modeling.

3.3.7 **Generalized Masking Effects** The EIA, acknowledges the importance of acoustic masking to marine organisms (BAR, p. 198) but overgeneralizes the effects of noise masking, failing to account for species-specific auditory ranges and behavioral needs. Different marine species rely on unique frequency ranges for communication, predator detection, and prey location [35,42,46–49]. A generalized approach that does not differentiate between species' auditory sensitivities can result in inadequate mitigation. For instance, what may be a moderate disturbance for one species could be catastrophic for another. Masking effects should be assessed separately for each species, given their varying hearing thresholds and reliance on the sonic environment.

3.3.8 **Disregard for Chronic Impacts** The EIA does not sufficiently consider the long-term effects of temporary injuries, such as hearing loss, resulting from seismic exposure. Temporary hearing loss can have severe long-term consequences if it impairs an animal's ability to communicate, forage, or avoid predators. Chronic exposure to noise may also lead to habitat abandonment or reduced reproductive success, ultimately affecting population resilience.[17,42,50] Seismic operations, particularly over 70 days, will result in chronic, not just temporary, impacts, leading to long-term harm to individuals and populations that depend on the proposed permit region.

3.3.9 **Disregard for Cumulative Impacts of Project Stressors** The EIA does not adequately consider the cumulative impacts of multiple noise sources, such as airguns, vessels, and ambient noise, over the duration of the 70-day seismic survey. Despite including a discussion on Cumulative Impacts (e.g., BAR section 9.2) generally, the BAR adopts a siloed approach in assessing risks. Per the EIA impact assessment protocol, the criteria required to score a "High" Cumulative Impacts is stated as: "Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/ definite that the impact will result in spatial and temporal cumulative change" (BAR, Table 39). Yet there is no transparent measure assessing the interactive impact of each potential threat. Instead, the TGS appeared to assess risks in isolation rather than integrating them. For instance, there is no apparent analysis concerning the impact to species that

experience temporary hearing loss (TTS) alongside habitat displacement- and although this would change the temporal and spatial scale of impact that is not reflected in the mitigation assessment. Similarly, the combined effects of anti-predator behaviors triggered by vessel noise and physiological stress associated with seismic noise may change reproductive output in fishes, which would alter the temporal scale of impact – but this scientific probability did not appear to change the risk assessment rating. This piecemeal approach – or at the very least the lack of transparency pertaining to how cumulative impact criteria were scored – significantly underestimates the true impact of the proposed activities.

3.3.10 **Disregard for Cumulative Impacts of Possible Multiple Projects** The EIA fails to propose adequate mitigation to prevent the impact of multiple exposures to marine organisms in association with other proposed survey projects in the region (e.g., Searcher and Gx Technologies). This scenario – multiple projects occurring simultaneously – was not quantitatively modeled within the Acoustics Specialist Report, addressed in the Marine Ecology Report, and therefore adequately assessed in the EIA. The EIA within the BAR considers the impact of the proposed exploration project isolation, with one brief mention of isolated impacts of multiple project (BAR, p. 211). This is a gross oversight that requires comprehensive consideration and mitigation strategies based in realistic data to remedy.

Each additional project in or near the proposed survey region is associated with a set of risks that compound when they occur in close spatial or temporal proximity. Most mitigation measures proposed to address the impact of anthropogenic noise in the EIA would be minimized or completely invalidated by the presence of additional exploration. Part of the EIA mitigation plan hinges on there being a 'safe place' for marine organisms to retreat to avoid the impacts of extremely high amplitude sound, or by minimizing the spatial and temporal scale of sound exposure associated with the project. These assumptions are untrue if multiple project occur simultaneously. The scale of sound propagation greatly exceeds the proposed 40 km mitigation zone proposed to account for the occurrence of simultaneous projects (BAR, p. 211). Moreover, depending on the temporal scale of the other project, this would extend the overall high noise exposure to the environment, rendering the modeled SEL in the Acoustics Report incorrect, increasing the probability for both PTS and TTS for marine organisms, and increasing the probability for elevated stress levels in marine organisms at a regional level. Noting that the sound of seismic exploration, vessels, and other anthropogenic noise sources can travel for hundreds or even thousands of miles, the 40km buffer between ships would have minimal mitigation impact. No additional mitigation measures were proposed (e.g. adjusting the timing of operations, altering seasonality, stopping in the presence of other operations, etc.).

3.3.11 **Flawed Scoring System** The EIA employs a scoring system that does not allow for population-level impacts or the meaningful incorporation of uncertainty. In data-deficient situations, this scoring system biases the assessment toward assuming minimal impact, leading to underestimation of real risks. There is a need to factor in

uncertainty and variability in population responses to ensure a precautionary approach is taken.

3.3.12 **Inadequate Mitigation Zone** The EIA's reliance on a 500 m mitigation zone is insufficient to protect marine life from the harmful impacts of seismic noise. The Acoustics Specialist Report explicitly indicates that behavioral impacts are expected for marine mammals at distances up to 3.8 km from the array source and for fish at 1.3 km. Similarly, a zone of 2-5 km is necessary to avoid significant impacts on squid and other cephalopods (BAR, p. 215). A 500 m zone does not adequately mitigate the risk of injury or behavioral disruptions, especially given the repetitive use of airguns over 70 days. The BAR and associated specialist reports failed to incorporate the best available statistical methods to model habitat abandonment or avoidance, which would provide a more accurate assessment of indirect impacts[16,19,51,52]

3.3.13 **Failure to Use Best Science** The EIA fails to incorporate the best available scientific practices in its mitigation strategies. For example, in the absence of comprehensive biological surveys, best practice recommends assuming the presence of sensitive species and applying conservative mitigation measures to avoid harm. The reliance on outdated scientific recommendations from the Acoustics Specialist Report results in insufficient mitigation strategies. The Specialist Report critiques this failure to integrate the latest scientific guidelines, such as those from Southall et al. (2021), which provide more accurate frameworks for assessing long-term noise impacts (Specialist Report, p. 57).

Selected section specific comments associated with proposed mitigation within the EIA

9.3.1.1 ACOUSTIC IMPACTS OF SEISMIC SURVEYS ON MARINE FAUNA

This section outlines the importance of sound in the marine environment and the broad impacts of the noise associated with seismic operations to the marine environment and fauna. The following specific points are made (p. 128, statistics per the BAR):

1. **Shipping noise** is a significant and persistent source of anthropogenic sound, particularly at low frequencies, and can propagate over large distances, affecting vast marine areas.
2. **The Application Area** for the proposed project lies within busy shipping routes, where ambient noise is expected to be high (90-130 dB) due to shipping traffic.
3. **Seismic surveys** use intense sound sources, which can also propagate over great distances, with sound transmission being influenced by factors like water depth, distance, and ocean conditions. Sound pulses change in character due to reflective boundaries (sea surface, seafloor, etc.).
4. **In shallow waters**, seismic sound can travel up to 75 km, while in **deep water**, detection ranges can exceed 1,000 km under ideal conditions.
5. **Marine animals' auditory masking** occurs when background noise interferes with their ability to detect important environmental sounds. The duration and repetition of seismic impulses can affect animals' hearing thresholds

Despite the BAR's identification of these threats, most of these concerns are not adequately addressed by the proposed mitigation measures. Below is a point-by-point consideration of these omissions.

1. ***Shipping noise:*** *is a significant and persistent source of anthropogenic sound, particularly at low frequencies.* Despite this, the BAR neither commissioned the modeling of noise associated with the seismic ship and vessel operations, nor conducted a baseline soundscape analysis to measure the potential changes associated with seismic operations. Mitigation measures did not include vessel speed limits or daily maximum hours a day of use, both which would minimize vessel noise associated with shipping operations. The EIA within the BAR determined pre-mitigation impact of vessel noise on marine fauna to be "LOW" however, there is no empirical data to support this.

2. *The Application Area for the proposed project lies within busy shipping routes, where ambient noise is expected to be high (90-130 dB) due to shipping traffic.* TGS failed to measure the *in situ* contributions of vessel noise to the proposed permit area or the adjacent areas likely to be ensonified by seismic operations. It is not possible to test this claim, or to assess how the proposed operations will alter baseline soundscapes. In the absence of *a priori* measurements and comprehensive modeling. While vessels within an environment are loud, seismic operations including vessel operation and have been demonstrated to elevate ambient noise conditions in all known cases, and in broader frequency ranges than anticipated.[4,53–58] Per the Acoustics Specialist Report, ambient sound values will well exceed the 90-130 dB range within and beyond the permitted area in association with seismic operations (Acoustics Specialist Report, Table 11).

3. ***Seismic surveys use intense sound sources, which can also propagate over great distances, with sound transmission being influenced by factors like water depth, distance, and ocean conditions. Sound pulses change in character due to reflective boundaries (sea surface, seafloor, etc.).*** In keeping with this point, the Acoustic Specialist Report indicated that "the directivity of received noise is dominated by the directionality of the source array." Simply put, the direction the sound is produced in, dominates the direction the sound impacts. Despite this, no mitigation measures were suggested to restrict directionality of sound sources to minimize impact to biologically sensitive areas within and beyond the proposed permit zone.

4. ***In shallow waters, seismic sound can travel up to 75 km, while in deep water, detection ranges can exceed 1,000 km under ideal conditions.*** While this statistic is an underrepresentation (seismic has in certain context been detected for up to 4,000 km [4]), the BAR is correct that seismic sound can be very far reaching. Despite this acknowledgment, and the demonstration in the Acoustic Specialist Report that loud persistent sound sources associated with the proposed project are up to at least 200 km (maximum modeled distance), there were no concrete mitigation measures suggested that would minimize the acoustic energy input into the ocean throughout the project or to assess impact at a broader spatial extent.

5. ***Marine animals' auditory masking*** *occurs when background noise interferes with their ability to detect important environmental sounds. The duration and repetition of seismic impulses can affect animals' hearing thresholds.* It is true that the sound associated with seismic operations can mask critical sounds; behavioral responses also include altering the timing of calling – which may also interfere with important information transfer. Additionally (though unaccounted for in the Acoustics Specialist Report) the seismic ship and support vessels will also mask sounds. Moreover, animals experiencing temporary hearing shifts, will have altered decreased hearing sensitivities, thus increasing the likelihood and impact of masking. Despite these realities, mitigation measures do not adequately prevent the elevation of ambient sound that will lead to masking at broad scales or at altered thresholds, or indeed measure changes in the soundscape from baseline levels. Further, while the zones of behavioral response were modeled in the Acoustics Specialist Report, zones of masking were not solicited by TGS for the report.

9.3.1.1.1 NOISE IMPACT ON WHALES AND DOLPHINS

The overall assessment of seismic noise impact on cetaceans was calculated based on the impact to the individual, rather than the population, thus downplaying the potential impact to cetaceans over broader temporal scales. The proposed mitigation zone falls well below the zone of acoustic response expected for physiological, behavioral, or masking impacts. The Acoustics Specialist Report indicates that behavioral impacts are expected in cetaceans at 3.8 km from the array source. The maximum zones of temporary threshold shifts (TTS, temporary deafness) for very-high-frequency cetaceans are within 650 m of the source (Acoustics Specialist Report, p. i). Under normal operations, TTS zones for low-frequency cetaceans extend up to 5 km from the survey lines. Based on the research available and integrated into the BAR, a 500 m zone is insufficient to prevent injury to animals, especially given the repetitive use of airguns over 70 days. This strategy does not minimize harm. Similarly, because it is currently unknown how the seismic operations will elevate ambient sound (no baseline soundscape analysis was conducted) or how far the sound is expected to travel (lack of total onsonificaiton range) it is not possible to calculate the potential range over which cetaceans will experience acoustic masking. Lastly, while MMOs and PAM operators are extremely useful in mitigating negative impacts on marine mammals, many species (e.g., deep diving odontocetes) surface after long (>60 minute) dives and are extremely difficult to identify at distances greater than 1 km, thus minimizing the effectives of MMOs for long range impacts.

9.3.1.1.6 NOISE IMPACTS ON MARINE INVERTEBRATES

Despite the information contained in the Marine Ecology Report indicating the potential impact of seismic operations on marine invertebrates, and squid specifically (death, injury, displacement), and the acknowledgment that the zone of acoustic impact of for cephalopods is broad (2-5 km, BARp. 204) the BAR and its associated reports erroneously claim that impact of seismic on invertebrates is LOW (see specific comments on the Marine Ecology Report on squid). The proposed mitigation, that MMO would watch for mass squid mortality is functionally meaningless. Squid are neutrally buoyant and therefore would not float to the surface; even if squid did float, given the size of the ship, the water current associated with vessel transit, and the camouflage of the animals, mass mortalities of squid wouldn't be visible from the seismic ship.

9.3.1.1.7 NOISE IMPACT ON PLANKTON

The EIA indicates that pre-mitigation impacts on planktonic communities (the base of the marine food web) would be MEDIUM pre-mitigation. Indicating, by the TGS' admission a potentially biologically meaningful impact. Despite this the BAR states that the "Application Area is located far offshore, it is not deemed necessary to implement mitigation measures to avoid the key spring spawning periods thereby mitigating potential impacts on plankton to some degree." (BAR, p. 204). Put plainly, the mitigation plan is to do nothing; yet according to the EIA this will reduce the threat from MEDIUM to LOW. This is unreasonable, and not based in science.

9.3.1.2.1 IMPACTS OF NON-SEISMIC NOISE (VESSEL AND HELICOPTER NOISE)

The significance of non-seismic noise is said to be "low" before and after mitigation. This cannot be assessed according to the BAR's own criteria in the absence of a baseline soundscape analysis. Vessel noise, particularly as it reaches CBAs, MPAs, and regions of ecological importance (seamounts and caverns containing deep water corals), will alter the soundscape in potentially meaningful ways. This could impact larval recruitment, predator-prey dynamics, and beyond. The EIA, and the reports it relied on for assessment, failed to quantify, model, or predict, elevated ambient noise associated with vessel or aircraft within or beyond the proposed permit area. The assumption that this noise does not meaningfully impact the environment cannot be assessed. No mitigation was suggested, this course of action is not based on scientific information.

4 SUGGESTIONS FOR REASSESSMENT OF NOISE IMPACTS

NOTE This is a **minimal selection** of suggested assessment and mitigation measures pertaining to acoustics impacts associated with the proposed seismic operations. These measures alone will not be sufficient to minimize the acoustic impact to the marine environment within and beyond the proposed permit region. These suggestions are needed in order to assess if or how to develop mitigation plans to minimize acoustic impacts. .

1. **Comprehensive Soundscape Analysis (1-Year Minimum) Prior to Project Implementation**
   Objective: Conduct a thorough baseline analysis of the soundscape within the habitat over a minimum of one year before project activities begin. This will help establish a baseline understanding of natural noise levels and seasonal variations, providing critical context for assessing the potential impact of the project's noise on the ecosystem.

2. **Model Full Spatial and Temporal Range of Ensonification for All Sound Sources**
   Objective: Model the full spatial and temporal extent to which anthropogenic sounds associated with the proposed project will inundate marine soundscapes, including the ensonification range for airgun operations within the proposed permit area, as well as the ensonification associated with seismic ship and support vessel transit within and beyond the proposed permit area.

3. **Inclusion and Consideration Population Level Impacts and Associated Uncertainty**
   Objective: Acknowledge the necessity of modeling population level impacts (including estimated proportion impacted) and incorporate uncertainty in population density

estimates for the relevant species (e.g., marine mammals, fish, etc.) by developing multiple density scenarios. This includes:

a. Assessing the risk to species under a range of plausible population densities, especially considering variability in population numbers.
b. Where available, use population abundance data and apply variability factors to estimate the proportion of the population that could be exposed to noise during the project's operational period (e.g., 70 days).

4. **Separate Mitigation for Direct (Injury) and Indirect (Behavioral) Impacts of Noise**
Objective: Differentiate between the direct impacts (e.g., physical injury) and indirect impacts (e.g., behavioral disturbances) of noise exposure on species and propose mitigation for each
   a. For **direct impacts**, model potential injury thresholds based on noise exposure.
   b. For **indirect impacts**, consider the latest version of the **probabilistic disturbance approach**, which incorporates various behavioral states (e.g., feeding, resting, migrating) and estimates the time spent in each state. This method will help refine understanding of how noise affects species' daily activities.
   c. Develop mitigation relevant to spatial and temporal ranges of each.

5. **Exposure and Risk Assessment Based on Behavioral States**
Objective: Rather than adopting a blanket seasonal approach, model exposure levels and risks based on species' behavioral states (e.g., breeding, feeding, migration) and proportion of the population engaged in each activity. This will allow for the development of an **operation schedule** that minimizes noise during critical behavioral periods, thus reducing potential disruptions.
   a. The model should take into account how noise influences different states, adjusting operations to align with periods when species are least sensitive to noise.

6. **Integration of Southall et al. (2024) Recommendations**
Objective: Implement the recommendations outlined by Southall et al. (2024) on managing anthropogenic noise. The study critiques current regulatory approaches adopted in the BAR which rely on simple thresholds for noise exposure criterion. Southall et al (2024) calls for more nuanced criteria that consider species-specific and context-dependent responses, including behavioral responses.

7. **Required Evaluation of Proposed Mitigation Measures**
Objective: Evaluate the effectiveness of proposed mitigation strategies for both direct and indirect impacts that include uncertainty. This should involve a **comparative analysis** of different mitigation approaches, such as noise reduction technologies, spatial or temporal restrictions, and habitat protection measures. The evaluation should include:
   a. Quantitative and qualitative assessments of the potential success of each measure.
   b. A comparison of the potential impacts before and after the implementation of mitigation measures.

c. Consideration of adaptive management approaches based on scientifically based zones of impact to allow for adjustments if initial mitigation measures prove inadequate.

8. **Incorporation of Real-World Detection Probabilities of Marine Mammal Observers into Risk Assessment and Mitigation Strategies**
Objective: Integrate **real-world detection probabilities** of Marine Mammal Observers (MMOs) into the risk assessment process and the development of mitigation strategies. These detection probabilities can vary significantly based on factors such as:
   a. **Species size** (larger species are easier to detect)
   b. **Group size** (larger groups are more noticeable)
   c. **Time of day** (e.g., detection can be lower during low light conditions such as dawn, dusk, or night)
   d. **Observer experience** (more experienced observers are likely to have higher detection success)
   e. **Animal behavior state** (for example, animals in more active states may be easier to spot than those resting or submerged)
   f. This incorporation will help **refine risk assessments** by accounting for the inherent variability in detection rates and potential missed detections, especially during times of high operational noise or challenging environmental conditions. Additionally, it ensures that mitigation measures (such as shutdowns or noise reduction) are based on more realistic expectations of detection success, thereby improving overall protection for marine mammals.

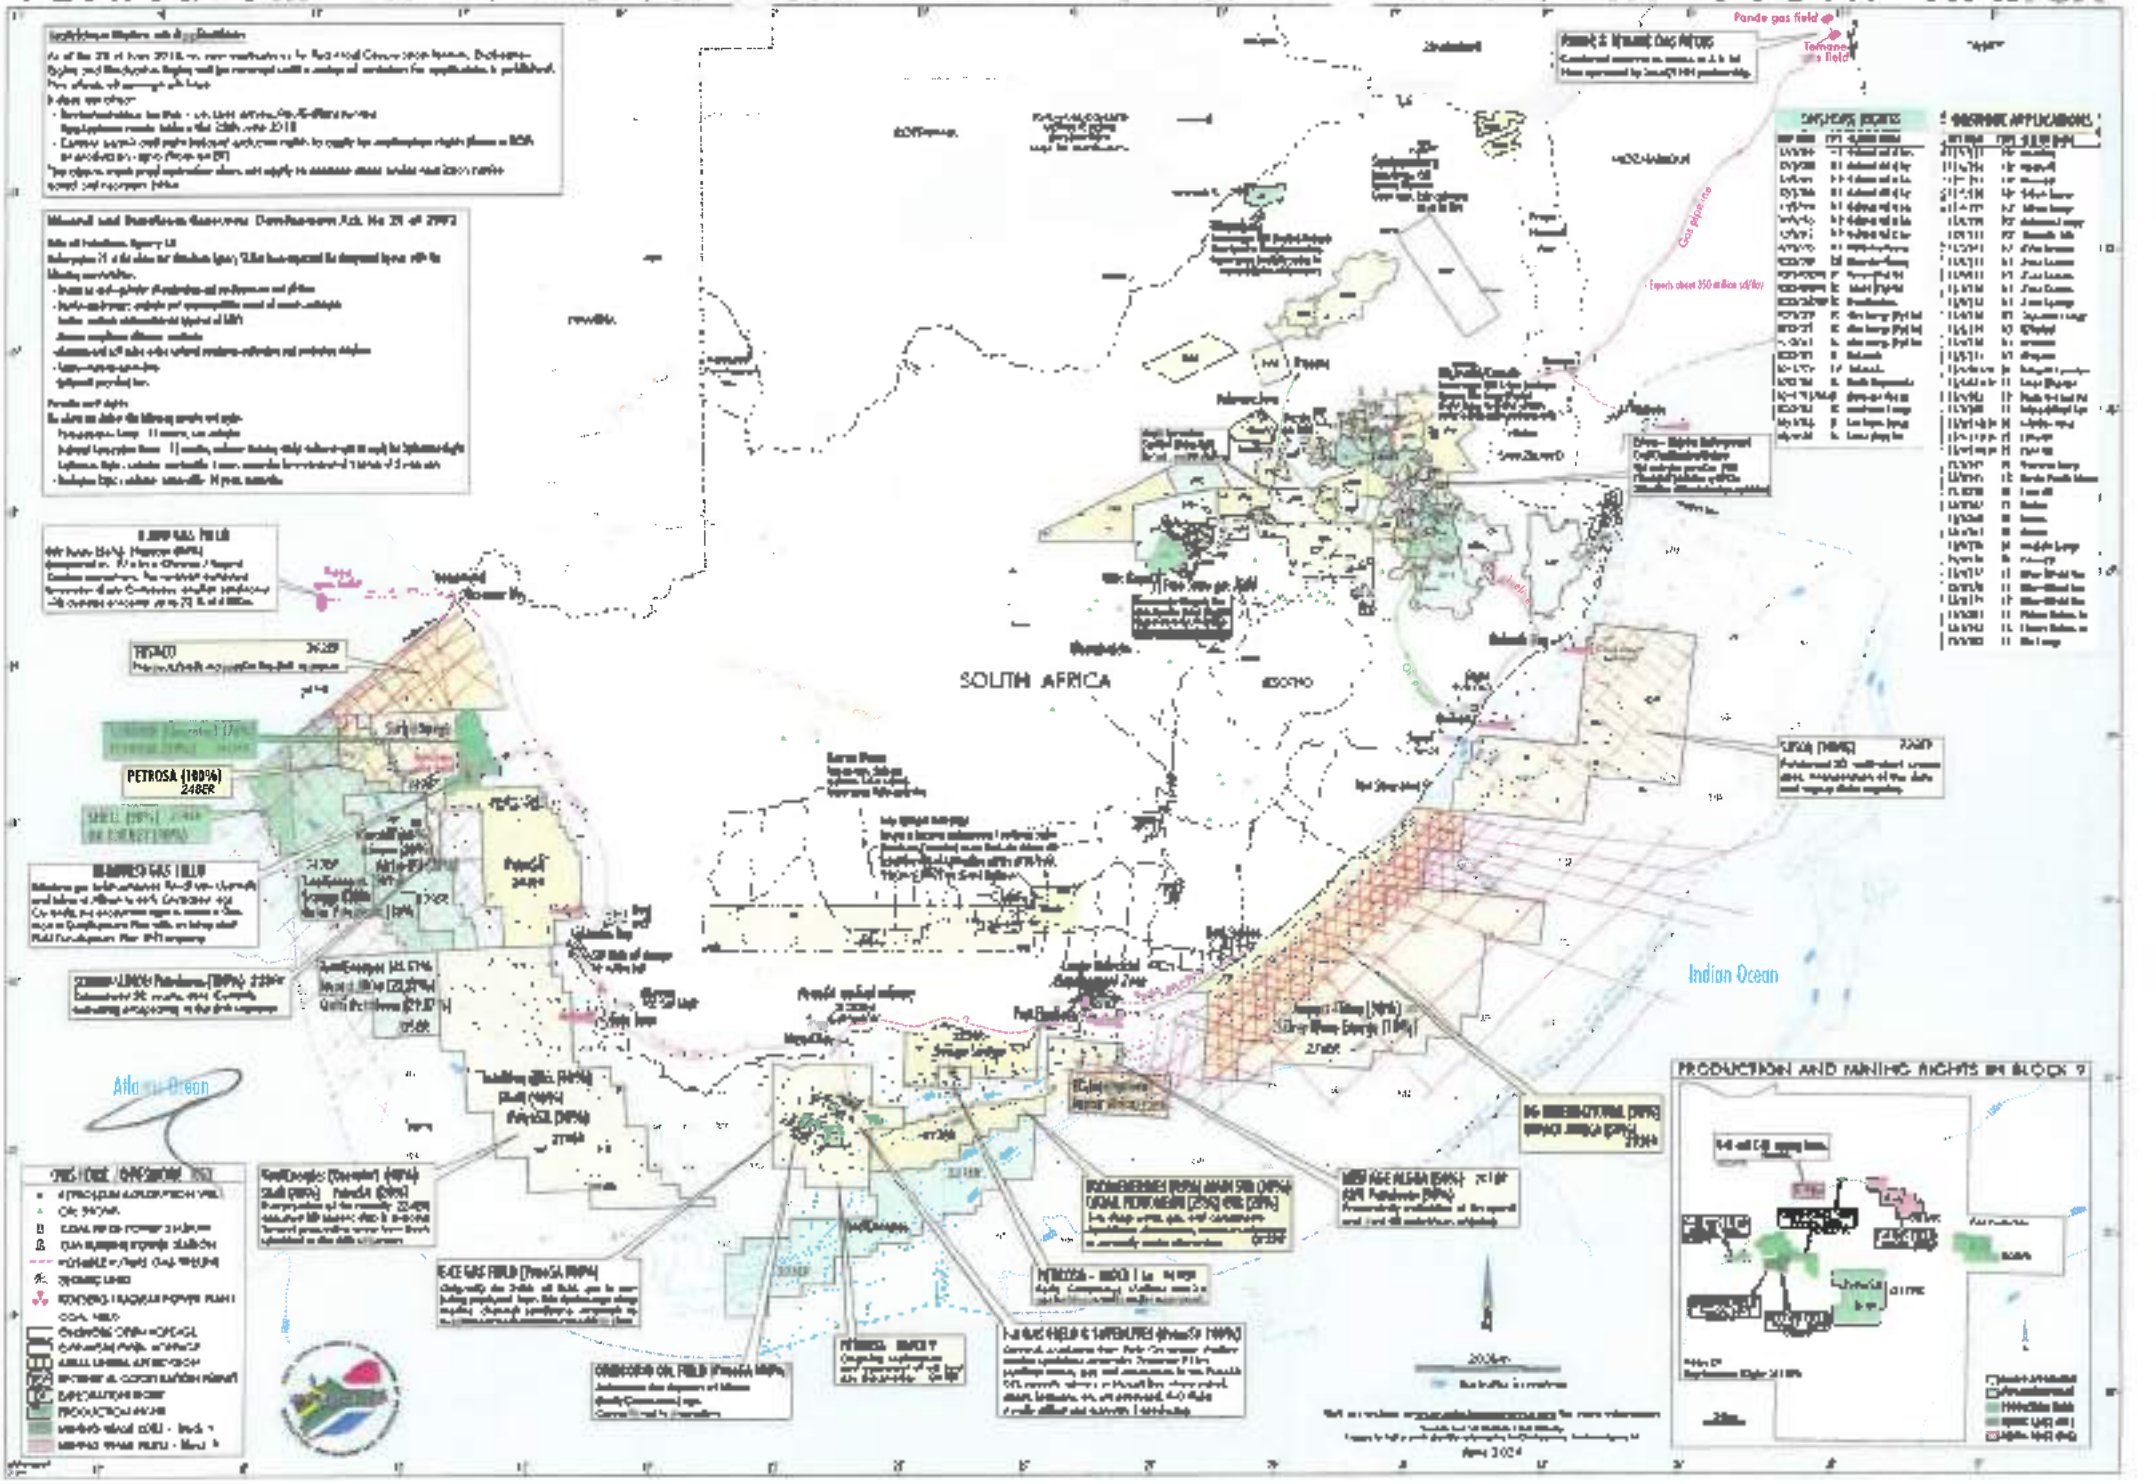
PETROLEUM EXPLORATION AND PRODUCTION ACTIVITIES IN SOUTH AFRICA



REPUBLIC OF SOUTH AFRICA

OPERATION PHAKISA

Unlocking the Economic Potential of South Africa's Oceans

Offshore Oil and Gas Exploration
Final Lab Report

15 August, 2014

2217
"A15"

Abstract

Context

- Although South Africa's oil and gas sector is in the early development phase, it has the potential to create large value to the country in the long run
- Developing an oil and gas industry takes decades; in Nigeria, it took 15-20 years from the moment of licensing until first production
- South Africa has possible resources of ~9 bn barrels oil and 11 bn barrels of oil equivalent of gas, but uncertainty is large
- Oil and gas exploration requires significant investments, particularly in South Africa's deep-water offshore environment where a single exploration well can cost over USD 150 mn. To achieve 30 exploration wells in the next 10 years, investments in the range of USD 3-5 bn are needed. Given that exploration success rates are below 15%, investors see these opportunities as risky

Vision – what success could look like

- In order to get a view of actual prospectivity, exploration activity must increase; the lab has set an aspiration to achieve 30 exploration wells in the next 10 years
- Assuming South Africa could achieve production levels of 370,000 barrels of oil and gas per day (of which the likelihood is hard to assess at this stage), this would mean up to 130,000 jobs are created with an annual uplift to GDP of USD 2.2 bn, while reducing the dependence on expensive oil and gas imports

What do you need to get there

- **Infrastructure** – although the infrastructure is currently not a constraint to exploration, particularly for gas, further coordination with other stakeholders may be helpful to incorporate the potential implications of offshore production into infrastructure plans
- **Environment** – to address concerns about a potential negative impact of offshore oil and gas exploration and production (E&P) several initiatives have been proposed, of which joint emergency response drills, and operationalisation of the international oil pollution fund are 2 examples of "quick wins"
- **Capability development** – a collaborative skills strategy roadmap and sub-surface research capability should be developed
- **Supply chain (local content)** – although still in the exploration phase, limited opportunities arise to develop local content (potential for local seismic work is assessed); a mechanism should be developed for the production phase based on global best practices
- **Institutional arrangements:** to maximise value for the country, adequate institutional governance is critical to ensure efficient and effective reservoir management, licensing, planning, data management and auditing
- **Legislative:** to affirm investor confidence, clarity and stability must be provided on the full legislative, regulatory and contractual package

ENVIRONMENTAL AUTHORISATION IN TERMS OF SECTION 24 OF NATIONAL ENVIRONMENTAL MANAGEMENT ACT, 1998 (ACT 107 OF 1998) AS AMENDED, READ WITH REGULATION 19 OF THE ENVIRONMENTAL IMPACT ASSESSMENT (EIA) REGULATIONS, 2014 AS AMENDED, FOR 3D SEISMIC SURVEY ACTIVITIES LOCATED BETWEEN APPROXIMATELY 25KM OFFSHORE OF ST HELENA BAY EXTENDING NORTH ALONG THE WESTERN COASTLINE TO APPROXIMATELY 220KM OFFSHORE OF HONDEKLIP BAY, ADJACENT TO THE NAMAKWALAND AND WEST COAST MUNICIPALITIES: WESTERN CAPE REGION.

I, Mr. Jacob Mbele, in terms of the powers delegated to me, have in terms of regulation 24 of the National Environmental Management Act, 1998 (Act 107 of 1998): Environmental Impact Assessment Regulations, 2014 (hereafter referred to as 'EIA Regulations') decided to grant an environmental authorisation (hereafter referred to as the authorisation) in respect of the application lodged to us on 06 September 2022. Herewith attached is the copy of the authorisation and reasons for the decision to grant.

You are instructed in terms of regulation 4(2) of the EIA Regulations to notify all registered interested and affected parties (I&APs), in writing and within fourteen (14) days of the date of the decision, of the outcomes of your application. You are also required to inform registered I&APs of the procedure to submit appeals against the decision as contained in the National

2023

Environmental Management Act, 1998 (Act 107 of 1998): National Appeals Regulations, 2014 (hereafter referred to as 'Appeals Regulations').

Should you wish to appeal the decision or any aspect thereof, you must submit an appeal in the prescribed form and in accordance with Chapter 2 of the Appeals Regulation, within twenty (20) days from the date of notification of the decision. The said must be submitted to the Minister of Forestry, Fisheries and the Environment, and copies sent to the Department of Mineral Resources and Energy (Head Office) and the Petroleum Agency SA by one of the following means:

1) Department of Forestry, Fisheries, and the Environment

mineral resources & energy

Department:
Mineral Resources and Energy
REPUBLIC OF SOUTH AFRICA

Enquiries: Mr. BP Mohasoa EAP Reg No.: 2022/4684 Email Address: Peter.Mohasoa@dmre.gov.za
Ref: 12/1/043

ENVIRONMENTAL AUTHORISATION IN TERMS OF
THE NATIONAL ENVIRONMENTAL MANAGEMENT ACT, 1998 (ACT 107 OF 1998) AS AMENDED ("NEMA")
AND THE 2014 EIA REGULATIONS AS AMENDED

IN RESPECT OF

THE PROPOSED 3D SEISMIC SURVEY ACTIVITIES OFFSHORE, OFF THE WEST COAST, SOUTH AFRICA

APPLICATION DETAILS

Application Reference Number	12/1/043
Holder of Environmental Authorisation	Searcher Geodata UK Limited
Location of the Activity	Located between approximately 250km offshore of St Helena Bay, extending north along the western coastline to the approximately 220km offshore of Hondeklip Bay over a number of Petroleum License Blocks.
Size of the Reconnaissance Permit Application Area	Approximately 3 000 000 ha (30 000 km²)

This authorisation does not negate the holder of the authorisation, of the responsibility to comply with any other statutory requirements that may be applicable to the undertaking of the proposed activity.

2223

DECISION ON ENVIRONMENTAL AUTHORISATION

ACRONYMS

BAR:	Basic Assessment Report
DEPARTMENT:	Department of Mineral Resources and Energy
ECO:	Environmental Control Officer
EA:	Environmental Authorisation
EIA:	Environmental Impact Assessment
EIA REGULATIONS:	EIA Regulations, 2014, as amended
EMPr:	Environmental Management Programme
I&APs:	Interested and Affected Parties
MPRDA:	Mineral and Petroleum Resources Development Act, 2002 (Act 28 of 2002), as amended
NEMA:	National Environmental Management Act, 1998 (Act 107 of 1998), as amended
Agency:	Petroleum Agency South Africa

The Department is satisfied with the information made available to it, and subject to compliance with the conditions of this Environmental Authorisation, that the applicant should be authorised to undertake NEMA EIA listed activities specified below. Details regarding the basis on which the Department reached this granting decision are set out in Section 5 and Annexure 1 of this Environmental Authorisation.

ACTIVITY (S) AUTHORISED

By virtue of the powers conferred on it by the National Environmental Management Act, 1998 (Act No. 107 of 1998) ("NEMA") and the Environmental Impact Assessment Regulations, 2014 ("EIA Regulations"), the Department hereby grants the Environmental Authorisation to Searcher Geodata UK Limited to undertake the NEMA EIA listed activities specified in section 3 below and as described in the BAR/EMPr submitted on 01 November 2022.

The granting of this Environmental Authorisation is subject to compliance with conditions specified under section 5 below.

1. DETAILS OF THE HOLDER OF THIS ENVIRONMENTAL AUTHORISATION

- Second round of advertisements announcing public meetings were placed in the same newspapers between 13 and 15 July 2022.

e) Poster placement in English, Afrikaans and IsiXhosa were placed at local public gathering places at various onshore locations.

f) Radio adverts were aired on KFM, Radio Namakwaland and Radio NFM in IsiXhosa, Afrikaans and English respectively.

g) A series of first round public meetings were held between 25 and 30 July 2022, and second round public meetings between 19 and 27 September 2022.

h) Comments and issues raised by Interested and Affected Parties were adequately addressed in the EIAR/EMPr.

4. Conclusion

In view of the above and having taken into consideration environmental management principles as set out in section 2 of NEMA, this Department is satisfied that the proposed activities will not be in conflict with the objectives of the Integrated Environmental Management set out in Chapter 5 of the National Environmental Management Act, 1998 and will not result in any detrimental risks to the environment and public. The authorisation is accordingly granted.

Searcher Geodata UK Limited	Applicant
Department of Mineral Resources and Energy	Competent Authority

Appeal: This is an appeal lodged against the decision taken by the Director General (DG) of the Department of Mineral Resources and Energy (DMRE) (competent authority), on 20 December 2022, to grant an Environmental Authorization (EA) to Searcher Geodata UK Limited (the applicant) for listed activities pertaining to the proposed seismic surveys on approximately 256 kilometres offshore of St. Helena Bay, extending north along the Western Coastline to approximately 220 kilometres offshore of Hondeklip Bay, adjacent to the Namakwaland and West Coast Municipalities: Western Cape Region.

1. BACKGROUND AND APPEAL

1.1 On 08 September 2022, the applicant lodged an EA application with the DMRE for listed activities pertaining to the proposed seismic survey on approximately 256 kilometers offshore of St. Helena Bay, extending North along the Western Coastline to approximately 220 kilometers offshore of Hondeklip Bay, adjacent to the Namakwaland and West Coast Municipalities: Western Cape Region. This application was lodged and processed in terms of the Environmental Impact Assessment Regulations, 2014, as amended (2014 EIA

EOS

2.52.4.2. I have noted the response by the applicant that the Namibian Government was pre-identified as a potential stakeholder / interested and affected party from the inception of the project in July 2022.

2.52.4.3. According to the basic assessment undertaken by the applicant/EAP, no transboundary impacts is expected as a result of the proposed activity, however, I&APs, including the Namibian government were consulted.

2.52.4.4. This ground of appeal is accordingly dismissed.

3. DECISION

3.1. In reaching my decision on this appeal, I have taken the following into consideration:

3.1.1 The information contained in the PROJECT FILE 12/1/043, with specific reference to the EA, BAR and EMPr.

3.1.2. The appeal submitted by the appellants on or about 09 February 2023;

3.1.3. The comments submitted by the DMRE on 24 March 2023; and

3.1.4. The responding statement submitted by the applicant on 22 February 2023.

3.2. In terms of section 43(6) of NEMA, I have the authority, after considering the appeal, to confirm, set aside or vary the decision, provision, or condition or directive, or to make any other appropriate decision.

3.3. Having considered the abovementioned information, and in terms of section 43(6) of NEMA, I have decided to dismiss the appeal, and to uphold the decision of the competent authority.

3.4. In arriving at my decision on the appeal, I have not responded to every statement set out in the appeal and/or responses thereof, and where a particular statement is not directly addressed, the absence of any response thereto should not be interpreted to mean that I agree with or abide by the statement made.

3.5. Should any party hereto be dissatisfied with any aspect of my decision; such party may apply to a competent court to have this decision judicially reviewed. Judicial review proceedings must be instituted within 180 days of notification hereof, in accordance with the provisions of section 7 of the Promotion of Administrative Justice Act, 2000 (Act No. 3 of 2000) (PAJA).

1 OVERVIEW

This document provides commentary and expert opinion on the scientific soundness of activities related to a planned seismic campaign in the Orange Basin region off the west coast of South Africa. Specifically, it examines whether Appendix 3.5 – "TGS: SOUTH AFRICA ORANGE BASIN 3D SEISMIC SURVEY SOUND TRANSMISSION LOSS MODELLING" (hereafter referred to as the "Acoustics Specialist Report") and Appendix 3.1 –"PROPOSED 3D SEISMIC SURVEY IN THE ORANGE BASIN OFF THE WEST COAST OF SOUTH AFRICA: BIODIVERSITY AND ECOSYSTEM SERVICES ASSESSMENT" (hereafter referred to as the "Marine Ecology Report")—both in support of the document "ENVIRONMENTAL BASIC ASSESSMENT REPORT: PROPOSED TGS ORANGE BASIN RECONNAISSANCE PERMIT, PASA REFERENCE: 12/1/040" (BAR)—adequately assess the environmental impact of anthropogenic noise associated with seismic operations and related maritime activities. This document includes commentary on the appropriateness of the content in the Acoustic Specialist Report and the Marine Ecology Report for developing mitigation strategies outlined in Section 9 ("Environmental Impacts Assessment," EIA) within the BAR, and the suitability of the proposed mitigation strategies in addressing potential harms related to sound produced by the proposed seismic operations.

1.1 PROJECT DESCRIPTION

TGS Geophysical Company (UK) Ltd is planning a seismic campaign in the Orange Basin off of the west coast of South Africa, pending the approval of the Reconnaissance Permit and vessel availability (the "project"). The Reconnaissance Permit Area spans approximately 57,400 km², located about 120 km offshore from St Helena Bay, extending to around 230 km offshore from Hondeklip Bay across several petroleum license blocks.

The survey will utilize a single 100 m seismic ship equipped with seismic sources and streamers, supported by up to two escort vessels of unknown size, and is expected to last around 70 days. The towed hydrophone streamers would be 8,000 meters in length and 2,000 meters, approximately the area of 3,000 football fields. The seismic pulse would be discharged every 2-6 seconds continuously during exploration operations at source levels (loudness at the source) between 200-255 dB re 1 µPa; for reference this is among the loudest produced anthropogenic sounds on the planet and is in the range of military weapons or explosions.

1.2 SUMMARY OF OPINION

The Acoustics Specialist Report and the associated Marine Ecology Report solicited by TGS fail to adequately demonstrate that anthropogenic noise generated by the proposed seismic campaign will not have significant ecological consequences for marine organisms and habitats at the permit location. This is primarily due to (1) the failure to recognize the anthropogenic noise from the project as chronic, (2) the failure to consider the full spatial extent of the noise generated by the project, (3) the omission of an assessment of underwater ambient sound conditions at the site prior to the proposed activities, (4) the failure to evaluate potential impacts on the broader marine community, including population-level effects, and (5) the failure to incorporate the most up-to-date and relevant scientific recommendations for assessing industrial noise impacts on marine ecosystems.

Consequently, the mitigation actions proposed in the associated Environmental Impact Assessment (EIA) are based on an inaccurate assessment of noise impacts and fail to meaningfully address the potential or likely impacts of anthropogenic noise on the marine environment related to the seismic exploration. Moreover, the mitigation actions proposed in the EIA fail to address the full range information contained in the specialist reports and reiterated within the text of the EIA, this willful omission results in even less comprehensive or appropriate mitigation measures.

1.3 PRIMARY FAILURES OF THE BAR and ASSOCIATED SPECIALIST REPORTS

1. Inadequate Premise and Limited Scope of Impact
   The Acoustics Specialist Report is founded on a flawed temporal premise and exhibits a narrow scope that fails to comprehensively address the complexities of anthropogenic noise impacts on the environment. As the primary resource used to assess mitigation needs associated with anthropogenic sound, the report is severely lacking. The fault of this should be attributed to TGS- who commissioned the report and determined the scope assigned to the contracting agency.

2. Appropriateness of Inference in Marine Ecology Report
   The Marine Ecology Report uses the outputs of the Acoustics Specialists Report in concert with data from a desk study to assess acoustic impacts on the marine environment; as such it contains the same flaws as the Acoustics Specialist Report and additionally underestimates the severity of seismic survey noise impacts. The report suggests insufficient mitigation strategies that fail to consider population-level impacts, soundscape level impacts, or chronic impacts associated seismic operations.

3. Insufficient Mitigation Measures within the EIA
   The proposed mitigation measures do not adequately address the potential acoustic impacts of the proposed project on the marine ecosystem, leaving significant risks unmitigated. The best available science was not considered when assessing the impact of the project, the scope of the available information was overly narrow, and the EIA selectively omits information included in the specialist reports and the broader literature.

2 GENERAL INTRODUCTION TO ANTHROPOGENIC NOISE IN THE MARINE ENVIRONMENT

Anthropogenic noise refers to sound generated by human activities, including infrasonic (below the range of human hearing) and ultrasonic vibrations (above the range of human hearing), as well as sounds within the human audible range. Anthropogenic noise poses a significant threat to organisms that rely on sound for vital life functions such as foraging, breeding, migration, and social interaction. Its effects are particularly severe in marine ecosystems, where sound travels vast distances with minimal energy loss. Most marine species have evolved to depend on sound as their primary sensory modality.

Social cetaceans and seabirds, including whales, dolphins, and penguins, rely on acoustic signals for communication, foraging, and social cohesion. Bottom-dwelling animals, fish, and invertebrates also respond to environmental sounds; for example, larval stages of various species use sound cues to time their transition from open water to benthic habitats. Alterations to the marine soundscape impact how marine animals interact with their environment, have the potential for both short term individual harm, and may result in shifts in long-term population dynamics.

Anthropogenic noise impacts ecosystems by disrupting communication, displacing species from critical habitats, altering foraging and predator-prey behaviors, increasing physiological stress, causing physical harm (including hearing loss), and even leading to mortality. Assessing these effects requires an interdisciplinary approach, combining ecology, resource management, acoustics, and statistics. Research on marine responses to noise has documented behavioral changes, auditory impairments, increased mortality, and reduced reproductive success. As such, any activity that generates noise may have significant ecological consequences, underscoring the need for comprehensive environmental impact assessments.

2.1 RELEVANT DEFINITIONS AND EXPLANATIONS

Characterizing Sounds

When determining the impacts of noise on an organism or an ecosystem, the sound must first be characterized. Sound is broadly characterized according to the following:

1. Duration: how long each signal lasts
2. Frequency (or pitch): how high, low, or broadband (simultaneously high and low) a sound is
3. Pulsivity: whether a sound is impulsive (like a series of bangs from fireworks) or continuous (like traffic noise)
4. Chronic versus discrete: Does the noise occur in a single short time period (like a jackhammer outside of an apartment window for a morning) or does it persist over long time periods (like an apartment which abuts a train track with trains passing by every day for many years).

Inappropriately characterizing noise has severe implications on individuals or organisms, and improper characterization can hide ecological impacts that may be significant. For example:

1. Duration: It would be misleading to characterizing the duration of a fireworks display that took place from 7pm until 11pm as having an average duration of 1.1 seconds (the length of time of a single firework).
2. Frequency: It would be misleading to say that simultaneously blowing 10,000 dog whistles (which are too high pitched for humans hear) would not impact a mother dog and her pups that were feeding 1 meter from the whistle blowers, simply because it doesn't substantially contribute to overall low frequency sound levels.
3. Pulsivity: It would be misleading to say that animals were capable of adjusting the timing of their calls to vocalize in between sound signals, if the sounds were continuous and there was no break between sounds.
4. Chronic vs. discrete: It would be misleading to say that the sound of a jackhammer outside of a bedroom window would have negligible effects on the apartment residents because it only occurred for three hours, when in reality the sound of the jackhammer occurred for three hours every day at 3am for 20 years.

Determining Ecological Baselines

To assess whether elevated noise levels associated planned human activities will impact an ecosystem, it is crucial to understand the environment's sound profile prior to the proposed human interference. This process is referred to as "determining the baseline soundscape," defined as the acoustic condition of a site before anthropogenic disturbance.

Components of a Baseline Soundscape Assessment: A baseline soundscape assessment should provide a thorough analysis of the sonic environment prior to proposed anthropogenic activities, focusing on spatial and temporal variations in sound levels and frequencies. Key components include:

1. **Identification and Characterization of Natural Sound Sources**: This includes biophony (sounds from living organisms), geophony (natural environmental sounds), and anthrophony (human-generated sounds).

2. **Data Collection Across Habitats and Seasons**: The assessment should capture sound data across different habitats and seasonal variations within a proposed site, enabling the detection of changes in sonic diversity and diel sound patterns associated with alteration.
3. **Evaluation of Sound Pressure Levels**: This includes assessing sound levels across ecologically relevant frequency ranges and identifying key signals, correlating these findings with ecological functions.
4. **Establishment of Reference Points for Ambient Noise Levels**: Identifying pre-project sound levels and sources is essential for future impact assessments and for effective project management and harm prevention. In the absence of pre-project sound levels, contributions of the project to the soundscape cannot be assessed, and preventative mitigation cannot be employed.

Mischaracterization or omission of baseline soundscape elements can significantly impact ecological interpretation, leading to negative ecological consequences across several scales. For example:

1. **Erroneously Assigning Acoustic Baselines**: An urban task force tasked with determining whether traffic noise affects the foraging habitat of a rare bird compares ambient noise levels during moderate traffic and a period with a single tractor-trailer truck. They conclude noise has no impact based on equivalent noise levels. However, a second task force compares recordings from a traffic-free Sunday morning and a Monday rush hour, revealing a 300% increase in ambient noise due to traffic—an important change that would be overlooked with a mischaracterized baseline.
2. **Omitting Frequency Analysis**: The same task force examines whether new power lines interfere with bat echolocation (ultrasonic frequencies >20 kHz). They report a small increase in average sound levels between 1 kHz and 30 kHz, concluding the noise increase is not ecologically significant. However, noise levels in the bats' communication range exceed 400% when power lines are active, indicating that their findings could lead to hearing loss in bats.
3. **Omitting Temporal Patterns of Sound Sources**: A contractor records baseline sounds for only 10 seconds each hour over a single autumn day, outside the typical mating and migration seasons. Consequently, the report lacks data on these critical signals and inaccurately concludes that elevated noise levels won't impact them. In reality, migrating and mating animals acoustically present for several months each year were simply not recorded.

3 SPECIFIC COMMENT AND CRITIQUE OF SPECIALIST REPORTS

3.1 INADEQUATE PREMISE AND LIMITED SCOPE OF ACOUSTICS SPECIALIST REPORT

3.1.1 Appendix 3.5 – "TGS: South Africa Orange Basin 3D Seismic Survey Sound Transmission Loss Modelling" (Acoustics Specialist Report), prepared by Environmental Impact Management Services Inc. (EIMS), presents a Sound Transmission Loss

Modeling (STLM) study to assess the spatial extent of noise impact on marine fauna within the proposed survey area off the West and South-West Coast of South Africa. This report was commissioned by TGS and used as the basis for risk assessment and mitigation planning associated with the proposed project.

3.1.2 The science contained within the report appears to be thorough. Due to fundamental flaws in its initial assumptions and the project scope requested by TGS, however, the Acoustics Specialist Report fails to accurately represent the real-world impacts of 3D seismic exploration on the marine soundscape and marine organisms within and beyond the proposed permit area. The report is based on incorrect premises regarding both the temporal and acoustic characteristics of the noise. EIMS' study focuses on the impact of discrete, 24-hour, pulsive noise on low-frequency sound levels in an otherwise pristine marine environment. Specifically, EIMS was tasked with identifying zones of impact from single airgun pulses and the cumulative effects of multiple airgun pulses over a 24-hour period (Acoustics Specialist Report, p. i).

3.1.3 In reality, the proposed project involves chronic pulsive noise coupled with continuous vessel noise over several months (70 days), significantly raising ambient sound levels in the low and mid-frequency ranges that affect marine mammals, fish, and invertebrates, both within and beyond the proposed project area. If the project were limited to 24 hours and only involved airguns, the study's assumptions might be valid. However, the cumulative effects of sustained high-intensity noise from multiple sources over 70 days are far more impactful than the short-term effects modeled in the report.

3.1.4 The Acoustics Specialist Report's failure to consider the added impacts of multiple sound sources on both direct (injury) and indirect (behavioral) effects on animals significantly undermines the assessment and its use for determining robust mitigation plans. The study exclusively considers the threats posed by airguns, primarily modeling the temporary threshold shifts (temporary deafness, TTS) and permanent threshold shifts (permanent deafness, PTS) associated with their use, with moderate to minimal consideration for behavioral impacts. However, additional sound sources—including two support vessels, a seismic ship measuring 100 meters in length, and generator noise on the ship—are also critical sources of noise associated with the proposed project. Recent research investigating marine mammal response to noise associated with seismic operations indicates that the behavioral response to seismic vessels is at the same magnitude as the airguns themselves[1] Notably, while airgun noise is generally considered low-frequency (<200 Hz), the frequency range produced by vessels is broader (also including mid-high frequency components), which were not included in the noise impact assessment. Noise from these additional omitted sources contributes to the overall ambient sound levels, collectively affecting the acoustic environment that marine organisms rely on for survival.

3.1.5 No baseline soundscape assessments were made for the proposed permit region within the Acoustics Specialist Report nor the BAR. No effort was made to quantify the naturally occurring sound levels for this region, the sources of naturally occurring sounds, or the seasonal and temporal cycles in ambient sound levels that may serve as

ecologically important cues. Given that marine organisms use sound for navigation, prey detection, predator avoidance, and foraging, alterations to the natural soundscape within and beyond the permitted region may have severe ecological consequences. In the absence of known natural ambient noise levels, it is not possible to assess how much the proposed activities will increase ambient noise levels in the soundscape—and therefore also not possible to assess underwater noise impacts.

3.1.6 The contribution of this project to the ambient soundscape is particularly relevant given that airguns produce some of the loudest known underwater sounds on the planet[2,3] and in some cases, can be detected 4,000 kilometers from the source[4]. The Acoustics Specialist Report failed to quantify how many total square meters would be ensonified as a result of the proposed project (see Wood 2010 for an example)[5]. However, based on the modeling reported, the detection of airguns is certain to expand beyond the permitted area and into the Critical Biodiversity Areas (CBA) and Marine Protected Areas (MPA) within and beyond the permitted area (Acoustics Specialist Report, Figure 17; Marine Ecology Report, Figure 42). Additionally, seismic and support vessels will operate beyond the limits of the proposed permit region, transiting through both CBAs and MPAs. The contributions of these sound sources to sensitive habitats were not modeled or addressed. Soundscape impacts and ensonification ranges were not solicited by TGS, and would have indicated a much broader spatial impact of the project than is currently reported

3.1.7 Noise produced from industrial activities cannot be physically contained underwater and may inundate critical biodiversity locations proximate to proposed operations and associated vessel activities. This requires careful consideration given the known impact of noise on marine mammals (stress, behavioral responses, reduction in foraging[6]), fish (behavioral responses, physiological responses, antipredator responses, death[7,8]), larval invertebrates (reduction in settlement, larval deformation [9–11]), and pelagic zooplankton (death[12]). Anthropogenic noise within CBAs and MPAs may harm, alter, or lead to death or population decline across a wide range of organisms and life stages that make up both ends of the trophic web. Because noise cannot be contained to the project site due, the impacts of noise are further reaching than the directing region of interest and must include coastal and adjacent pelagic areas as well.

3.1.8 An adequate baseline assessment of the acoustic properties of the soundscape—including biological sources of ambient sound, environmental sources, and ambient sound levels—is needed to complete an assessment of underwater noise impacts. Broader-scale sound propagation modeling, including the total range of ensonification associated with airguns and general project operations (seismic ship returning to port, support vessels, aircraft), throughout both pelagic and coastal habitats – inclusing seismic ship travel routes – is essential for adequately assessing project impact, risk, and mitigation strategies. This is particularly relevant for the Child's Bank, the Tripp Seamount, Cape Canyon and Cape Valley, which will likely experience changes in ambient soundscape conditions associated with the project. The report models ensonification up to 200 km, and notably the project is associated with high noise values up to that range (e.g., Acoustics Specialist Report, Figure 17).

3.1.9 The Acoustics Specialist Report overlooks the broader ecosystem-scale consequences of injuries caused by anthropogenic noise. The report focuses primarily on direct physical injuries to marine organisms, such as hearing damage from airgun blasts. This is not a comprehensive assessment. Temporary or permanent hearing loss, stress, and direct or indirect death in fishes and invertebrates are all physical consequences of anthropogenic noise exposure. However, the repercussions of such injuries extend beyond individual organisms and can affect entire ecosystems. When marine mammals or fish experience hearing loss, their ability to communicate, navigate, and locate predators or prey is compromised. This impacts their survival and can also disrupt predator-prey dynamics within the ecosystem, leading to population imbalances. Additionally, both injuries and anthropogenic noise in isolation can lead to stress responses in affected species, potentially resulting in altered reproductive success and decreased population resilience. The failure to adequately assess these ecosystem-level consequences limits the understanding of how noise pollution can disrupt ecological interactions and degrade marine biodiversity.

3.1.10 In addition to the direct impacts on individual animals, the report fails to consider the population-level consequences of behavioral changes induced by noise exposure. Noise from airgun activities can lead to significant shifts in the behavior of marine species. Responses of fishes to anthropogenic noise include reduction of anti-predator response, which leave individuals at higher risk of being eaten, acoustic masking of breeding sounds which may impact species at the population level, and reduced breeding success [2,13,14]. Marine mammals may alter their vocalization patterns, leading to reduced communication effectiveness. Fish may also exhibit changes in schooling behavior or abandon critical habitats due to increased noise levels. Such behavioral changes can affect reproduction rates, survival, and population dynamics over time. Furthermore, if key species alter their foraging behaviors or habitats, the repercussions can cascade through the food web, impacting other species reliant on them. The Acoustics Specialist Report's neglect of the consequences of behavioral shifts and their population-level impacts undermines the comprehensive assessment needed to understand the full ramifications of the proposed project on marine ecosystems.

3.1.11 The report also fails to quantify the number of marine animals likely to be acoustically impacted by airgun and other anthropogenic noise sources, missing an opportunity to address critical factors such as sex and behavioral state that influence vulnerability to noise exposure. Research indicates that certain demographics, such as nursing females, may be more sensitive to noise due to their specific behavioral contexts[15]. To fully understand the implications of noise exposure, it is essential to estimate the proportion of populations that could be affected by the proposed activities, particularly for vulnerable species. Furthermore, long-term consequences for impacted individuals can include decreased reproductive success and altered migration patterns[16,17], which can lead to population declines over time. A robust assessment would not only quantify the number of individuals affected but also evaluate the potential implications for population viability, particularly in the context of ongoing anthropogenic pressures[18]. This level of analysis is critical for informing appropriate mitigation strategies and ensuring the long-term sustainability of marine populations.

3.1.12 Since the release of the Acoustics Specialist Report, more recent scientific studies have emerged that challenge the premise of using blanket sound exposure level (SEL) or sound pressure level (SPL) thresholds to assess the impacts of anthropogenic sound on marine animals (Southall 2024). The Acoustics Specialist Report heavily relies on Southall (2019) to justify using these thresholds to determine varying levels of risk, while omitting the caveats included in the 2019 publication. Southall 2019 states that "***The approaches [in Southall (2019)] are not applicable in evaluating potential auditory effects of chronic noise exposure over periods of weeks, months, or years.***"[19]

3.1.13 In the updated guidelines, Southall (2024) again explicitly states that "simplistic received level-only step-function 'thresholds' indicating a binary lack or presence of response for any sound type are outdated and inconsistent with the best scientific information available"[19]. The Acoustics Specialist Report relies on exactly these binary thresholds, despite strong scientific evidence that this method is flawed[18,19]. Moreover, Southall (2024) highlights the issue of appropriately assessing the temporal scale (chronic impacts versus acute impacts) as a major flaw in the method used in the Acoustics Specialist Report. According to Southall (2024), "Where the acute exposure-response severity scale-based assessment approach really falls short is in the evaluation of repeated or sustained exposures for aggregations and/or local populations of animals on broader spatial and temporal scales." Given the multiple months of sound exposure to this ecosystem (70 days), this should be considered a chronic rather than acute sound source.

3.1.14 Beyond the 2024 publication, which the agency responsible for the Acoustics Specialist Report may not have had access to, Southall (2021) offers clear recommendations on acoustic exposure and the types and severity of behavioral responses, focusing on vital rates during acute events. Notably, Southall (2021) was not cited in the Acoustics Specialist Report, despite the report's goal of determining zones of impact for behavioral responses Acoustics Specialist Report, p. i). Given the Acoustics Specialist Report's reliance on Southall (2019), it should be assumed that the work of Southall—internationally regarded as industry standard and best practice—is considered reliable by EIMS. The omission of the most recent work is yet another indication that the Acoustics Specialist Report fails to reach the necessary depth to be used for reliable environmental impact assessment. These flaws can be predominantly associated with the scope of the project as requested by TGS.

Summary of Comments on Acoustic Specialist Report:

1. **Inaccurate Assumptions in Acoustic Specialist Report:** The report is based on incorrect assumptions, primarily focusing on short-term impacts from 24-hour airgun pulses. However, the actual project will involve 70 days of chronic, high-intensity noise, including both airguns and continuous vessel noise, leading to significantly higher impacts than modeled.
2. **Underestimated Noise Sources:** The study overlooks the noise contributions from multiple sources, including support vessels and generator noise, which affect both low and mid-frequency ranges critical to marine fauna and elicit behavioral responses. These omitted noise sources exacerbate the overall impact of seismic operations on the marine soundscape.

MS

3. **Lack of Baseline Soundscape Assessment:** No baseline data on natural ambient noise levels or soundscape characteristics in the project area were collected, making it impossible to accurately assess how much the proposed activities would increase ambient noise levels.
4. **Broader Spatial Impact Unaccounted For:** The report fails to quantify how far noise will travel beyond the project area, particularly into Critical Biodiversity Areas (CBAs) and Marine Protected Areas (MPAs), where noise could have far-reaching ecological consequences.
5. **Insufficient Consideration of Ecosystem-Level Consequences:** The report focuses primarily on direct physical injuries (such as hearing loss) but does not adequately address the indirect effects on behavior, communication, and predator-prey dynamics, which could disrupt entire ecosystems.
6. **Failure to Address Behavioral and Population-Level Impacts:** Noise-induced behavioral changes, such as altered communication or abandonment of critical habitats, are not properly assessed. These changes could lead to population-level consequences, affecting reproduction, survival, and overall ecosystem stability.
7. **Outdated Noise Thresholds and Methodologies:** The report relies on outdated sound exposure thresholds that fail to account for the chronic nature of the project's noise impacts. More recent scientific guidelines suggest that this approach is insufficient for assessing long-term impacts on marine animals.
8. **Missing Quantification of Impacted Marine Animals:** The report does not estimate the number of marine animals likely to be affected by the noise, nor does it consider the heightened vulnerability of specific demographics, such as breeding males or nursing females, to noise exposure.
9. **Need for Scaled Sound Propagation Modeling:** The report requires a broader-scale sound propagation model and an assessment of the full spatial and temporal extent ensonification.

3.2 COMMENTS ON APPROPRIATENESS OF INFERENCE IN MARINE ECOLOGY REPORT

3.2.1 Appendix 3.1 – " PROPOSED 3D SEISMIC SURVEY IN THE ORANGE BASIN OFF THE WEST COAST OF SOUTH AFRICA: Biodiversity and Ecosystem Services Assessment " (Marine Ecology Report), builds on the information provided in the Acoustics Specialist Report. As such, it shares same shortcomings, as well as additional issues with scope, depth, and inappropriate inference of acoustic information and application to mitigation strategies.

3.2.2 The Marine Ecology Report mirrors the shortcomings of the Acoustics Specialist Report by considering TTS an acceptable impact after mitigation, despite significant unknowns regarding the consequences of temporary hearing loss for affected populations and species. The Marine Ecology Report fails to account for the potential impacts of repeated noise exposure over multiple days, which could have more serious long-term effects that those assumed in the report. Established methodologies, such as those from Wood (2010) and Southall (2024), provide

guidance on assessing environmental impacts based on sex and behavioral states. However, the Marine Ecology Report neglects to incorporate these variables or critically to estimate the total proportion of marine populations of any species likely to be affected by the 70-day project. This omission occurs, despite the acknowledgement that portions of the proposed permit area are ecologically valuable for critical species and are in some cases considered vulnerable to human activities (Marine Ecology Report, "3.4.2 Conservation Areas and Marine Protected Areas"). Instead, the report applies the same simplistic binary threshold approach as the Acoustics Specialist Report, without considering chronic impacts or population level consequences.

3.2.3 In the case of marine mammals, prolonged exposure to noise is associated with chronic stress, internal and external injuries, displacement from breeding and foraging areas, altered migratory patterns, and permanent hearing loss[17,20-23]. Despite the vulnerability of local cetacean species such as humpback whales, sperm whales, Bryde's whales, and beaked whales found in the proposed permit area (Marine Ecology Report, Table 7) neither the Marine Ecology Report nor the Acoustics Specialist Report adequately addresses the risks associated with chronic noise exposure for these animals at the individual or population level. The assumption was made that animals would likely leave the area, but there was no quantitative estimation of the number of individuals impacted, the probability of habitat abandonment, the change in probability associated with age, sex, or behavior state (e.g. cows and calves versus adult males). This is particularly critical for data deficient species (fish, invertebrates, benthic organisms in abyssal regions) and deep diving odontocetes expected to use much of proposed region.

3.2.4 The Marine Ecology Report and associated EIA recommendations (BAR Section 9: Environmental Impact Assessment) fail to adequately suggest mitigation measures that will address the acute risks of seismic operations to the marine environment. The proposed measures, including a 500 m buffer around sensitive areas, a 500 m mitigation zone, Marine Mammal Observers (MMO), Passive Acoustic Monitoring (PAM), and operational responses based on animal proximity, are inadequate. For example, the report acknowledges that certain species, including beaked whales, are at risk of fatal acoustically induced decompression sickness —a behavioral response with an acute outcome (Marine Ecology Report, p. 67). Very high frequency cetaceans, which includes most odontocetes and beaked whales and will be impacted at ranges of 650 m (injury) and 3.8 km (behavioral responses), yet the mitigation zone is only 500 m. This is a clear misalignment between the proposed mitigation strategies and the data driven spatial extent of impact to marine species. Per the information included in the Marine Ecology Report, this misalignment may result in odontocete fatality.

3.2.5 Similarly, the Marine Ecology Report downplays the impact of noise on invertebrates and prey species, and the report suggests ineffective mitigation strategies to minimize the impact of seismic operations. While the report acknowledges the physiological and behavioral responses of squid (Marine Ecology Report, "4.3.6 Impacts of Seismic Noise

on Marine Invertebrates")— a primary prey source for marine mammals, including beaked whales, in Southeast African waters [24,25]—it incorrectly downplays squid mortality as having a LOW impact due to temporal and spatial scale. The report claims the impact on squid would be REGIONAL and IMMEDIATE- 1.5 months, but mortality is permanent and behavioral responses of surviving squid will likely occur beyond the permitted region, as the acoustic influence zone (2–5 km) extends beyond the survey area during operations (EIA, p. 215, area (Acoustics Specialist Report, Figure 17; Marine Ecology Report, Figure 42). The loss of squid would significantly affect trophic interactions, especially in a system already low in food sources. The report's claim that the removal of squid (a scarce resource) is low impact, is akin to draining a desert oasis and labeling the impact low because water is rare there anyway.

3.2.6 Additionally, the proposed mitigation measure intended to minimize harm to cephalopods —"Terminate seismic shooting upon observing any obvious mass squid mortalities estimated by the MMO as a direct result of the survey"—is ecologically unsound. Squid, which are found at depth, are neutrally or negatively buoyant and will not float to the surface for meaningful observation [26]. Even if they did float to the surface, they are highly camouflaged and ship movement would scatter them, making detection by the MMO virtually impossible. This suggestion that MMO's would be capable of reporting squid mortality is unrealistic, and the consequences of squid mortality are ecologically meaningful.

3.2.7 Impacts to Plankton and Ichthyoplankton were considered MEDIUM before mitigation, and LOW after mitigation. However, the proposed mitigation measures – for example no seismic operation within 5 km of important ecological areas – directly minimize the duration or extent of high source level sounds inundating the marine soundscape (see Figure 45a, Marine Ecology Report for a visualization of spatial scale, see also Madsen et al 2006)[27]. Noise associated with seismic operations will extend well beyond 5km, and vessel noise within ecologically vulnerable areas may have meaningful impacts that were omitted from this assessment. Fishes exposed to anthropogenic noise experience reduced anti-predator responses, leaving them more vulnerable to predation, acoustic masking of breeding sounds, reduced breeding success, temporary or permanent hearing loss, stress, and death[17,28,29]. Many larval invertebrates and fishes, such as corals, shellfish, and crustaceans, rely on sound to locate suitable habitat for settlement—the transition from their pelagic phase to a permanent location.[30–37] Acoustic masking of environmental cues within MPAs CBAs or other vulnerable habitats exposed to both seismic and vessel sounds may disrupt this process for key structure-building organisms.

3.2.8 Importantly, like the Acoustics Specialist Report, the Marine Ecology Report fails to consider population-level consequences for any species of interest. It makes no effort to quantify the number of individuals affected by the proposed activities or to assess the potential short- and long-term impacts on population dynamics. These omissions minimize the overall consequences of the proposed seismic activities. Understanding population-level impacts is critical, as disruptions to even a small number of individuals can have cascading effects on the species' reproductive success, genetic diversity, and

long-term survival, or may have meaningful trophic implication as prey species (like squid) grow scarce.

3.2.9 Lastly, the Marine Ecology Report fails to quantify soundscape properties in relation to other oceanographic features, such as bathymetry and currents. Since sound is the primary way marine organisms interact with their environment, the omission of a basic soundscape description and the potential impacts of the proposed project on it is a significant oversight.

Summary of Comments on Marine Ecology Report:

1. **Inadequate Consideration of Temporary Threshold Shifts (TTS)**: Based on mitigation suggestions the Marine Ecology Report TTS an acceptable post-mitigation outcome and fails to address the long-term consequences of temporary hearing loss to individuals of specific species or populations. There is also no consideration for the cumulative effects of multiple days of noise exposure. It overlooks more detailed approaches, such as assessing impacts based on species' sex and behavioral states, and neglects to estimate how much of the marine population will be affected by the 70-day project.
2. **Chronic Noise Exposure Risks**: The report downplays the significant risks of prolonged noise exposure for vulnerable cetacean species (e.g., humpback whales, sperm whales, beaked whales). It fails to assess how chronic noise might cause stress, injuries, altered migration patterns, and permanent hearing loss. There is also no quantitative estimation of how habitat alteration might affect these species.
3. **Insufficient Mitigation for Acute Noise Impacts**: The mitigation strategies proposed, including a 500 m buffer zone, are insufficient to minimize acoustic impacts to marine species (e.g, beaked whales and cephalopods). This highlights a failure to align mitigation efforts with the real world risks.
4. **Failure to Address Population-Level Impacts**: The report does not estimate how many individuals will be affected or assess the broader population-level consequences of direct or indirect harm, which downplays the long-term impacts of seismic exploration to this marine ecosystem.
5. **Omission of Soundscape Analysis**: The report neglects to assess the soundscape in relation to key oceanographic features (e.g., bathymetry, currents), despite sound being critical for marine organisms' interactions with their environment.

Overall, the report underestimates the severity of both acute and chronic noise impacts on marine life and offers inadequate mitigation strategies without accounting for population-level or soundscape effects.

3.3 INSUFFICIENT MITIGATION MEASURES PROPOSED WITHIN BAR SECTION 9 "ENVIRONMENTAL IMPACT ASSESSMENT" (EIA)

Throughout, the EIA fails to effectively propose mitigation measures that will address the acoustic impacts of seismic operations on the marine environment. Broad criticisms of the BAR's approach to mitigating acoustic impacts as well as specific criticisms on mitigation measures are below.

Broad Concerns Associated with BAR Section 9, Environmental Impact Assessment (hereafter "EIA")

3.3.1 **Failure to Address Habitat Variability:** The BAR fails to adequately account for the variability in habitat sensitivity within the proposed permit region. The region in question displays significant bathymetric variability (BAR, p. 46), with habitat use and biodiversity differing greatly throughout the area (Marine Ecology Report, p. 19). For example, the Marine Ecology Report highlights the continental slope region (200–2000 meters in depth) as likely to support cetaceans and endangered fishes (Marine Ecology Report, Table 1 & p. 50), yet, the EIA (BAR, Section 9 "Environmental Impact Assessment") does not propose targeted mitigation measures for activities on the continental slope. Environmental mitigation measures should consider different operational behaviors based on habitats expected to harbor higher biodiversity or be home to species of concern.

Different marine habitats support distinct species assemblages, each with its own sensitivities to human-induced disturbances. The lack of appropriate mitigation in certain regions could result in physical damage to sessile organisms that inhabit specific habitats but lack the ability to abandon an environment when seismic operations commence. Alternatively, mobile organisms like cetaceans are more likely to congregate along continental slopes where nutrient upwelling attracts prey (Marine Ecology Report p. 50). Ignoring habitat-specific sensitivities increases the risk of disrupting critical ecological processes

3.3.2 **Inconsistencies within the BAR**: The BAR and associated EIA contain inconsistencies. For example, the BAR proposes a long-term soundscape analysis for acoustics mitigation (BAR, p. 259) but fails to specifically include this measure in mitigation plans or to indicate spatial and temporal extent as part of the preventive strategies. The BAR also specifically acknowledges the need to minimize ambient sound levels associated with seismic operations (BAR, p. 245), yet requires no concrete mitigation measures regarding implementing technological or operational adjustments.

The EIA makes broad recommendations without considering the specific environmental conditions or the species most at risk at any given location or time of year. For example, seismic operations are proposed for January-May to minimize impact to baleen whales and commercially important fisheries - yet the BAR states that "it should also be kept in mind that some of the migratory species are now present year round off the West Coast, and that certain baleen and toothed whales are resident and/or show seasonality opposite to the majority of the baleen whales" (BAR, p 244). Despite this acknowledgment, these data were not meaningfully incorporated into planning or mitigation.

Effective EIAs should provide consistent, integrated, and transparent evaluations of all potential risks. A fragmented approach can result in a gross underestimation of cumulative or synergistic effects, where multiple stressors interact to amplify the harm caused.[38]

3.3.3 **Overly Optimistic Reliance on MMOs and PAM** The EIA fails to provide a clear scientifically driven, adaptive plan for real-time responses based on monitoring during the seismic survey. The existing plan incorporating real-time monitoring data (e.g., Passive Acoustic Monitoring (PAM) or Marine Mammal Observers (MMOs) is touted as a catch all to mitigate nearly every acoustic impact. MMOs, however, are limited in the scope and scale of their observations and PAM only captures loudly vocalizing animals (essentially omitting invertebrates and fish). Research indicates that the visual extent of MMOs from large ships is limited to 1 km, [5,18] yet per the Acoustics Specialist Report and the Marine Ecology Report acoustic impacts to marine mammals occur well beyond this range. MMOs are tasked with documenting mammals, fish, turtles, seabirds, fishes and invertebrates. This is both unrealistic and unreasonable. Many species of concern (e.g., odontocetes like sperm whales or beaked whales) have dive times in excess of one hour and surface intervals of less than a minute[39,40], making them hard to sight. Invertebrates, like squid, are negatively or neutrally buoyant[41] and aren't likely to be at the water's surface. Similarly, most fish species can't be reliably cited from a ship observation platform. Thus, while MMOs and PAM operators are crucial for reducing seismic operation impacts, they are not a panacea to address all potential risks.

3.3.4 **Incorrect Temporal Scale** The EIA focuses on short-term acoustic impacts (seconds to hours), despite the project involving approximately 70 days of seismic operation. This narrow focus disregards the long-term implications of chronic noise exposure. Prolonged anthropogenic[20,42,43] noise can lead to cumulative effects such as chronic stress, hearing damage, and altered behavioral patterns in marine species.[17] These chronic impacts, especially over the course of two months, are more likely to disrupt population dynamics, such as habitat avoidance or disrupted breeding patterns, which were overlooked in the assessment. Noise from the seismic survey is both chronic and spatially far-reaching, making the EIA's temporal scope inaccurate (See Commentary on Acoustics Specialist Report).

3.3.5 **Unknowns Are Disregarded** The EIA does not sufficiently account for unknown variables, including species-specific responses, role of behavioral states, lack of biodiversity data and ecosystem sensitivities. Uncertainty is inherent in ecological impact assessments, particularly when dealing with complex, dynamic marine ecosystems. It is essential to adopt the precautionary principle in such cases, ensuring that mitigation measures err on the side of caution to protect ecosystems from unforeseen consequences [18,44]. By failing to address these unknowns, the EIA underestimates in the scoring system and in its overall assessment the potential impacts of the seismic activity on species and habitats. The failure to collect baseline data significantly increases uncertainty; despite this, the EIA does not recommend commissioning ecological studies to address biological unknowns.

3.3.6 **Disregard for Far-Field Sound** The EIA does not adequately consider the effects of far-field sound, which can propagate over long distances and affect distant marine life. On page 58 of the BAR states that for areas that "receive the sound in the far field only, no detrimental effects to the communities or to individual benthic species are expected" (BAR, p. 58). However, seismic noise can travel thousands of kilometers [4], disrupting long-range communication among marine species such as cetaceans.[45] Far-field sound from seismic airguns will extend well beyond the immediate operational area, including into Critical Biodiversity Areas (CBAs) and Marine Protected Areas (MPAs) (see commentary on Acoustics Specialist Report and Marine Ecology Report), yet the EIA does not quantify the extent or ecological consequences or far field sound, nor does the EIA recommend broader scale acoustic modeling.

3.3.7 **Generalized Masking Effects** The EIA, acknowledges the importance of acoustic masking to marine organisms (BAR, p. 198) but overgeneralizes the effects of noise masking, failing to account for species-specific auditory ranges and behavioral needs. Different marine species rely on unique frequency ranges for communication, predator detection, and prey location [35,42,46–47]. A generalized approach that does not differentiate between species' auditory sensitivities can result in inadequate mitigation. For instance, what may be a moderate disturbance for one species could be catastrophic for another. Masking effects should be assessed separately for each species, given their varying hearing thresholds and reliance on the sonic environment.

3.3.8 **Disregard for Chronic Impacts** The EIA does not sufficiently consider the long-term effects of temporary injuries, such as hearing loss, resulting from seismic exposure. Temporary hearing loss can have severe long-term consequences if it impairs an animal's ability to communicate, forage, or avoid predators. Chronic exposure to noise may also lead to habitat abandonment or reduced reproductive success, ultimately affecting population resilience.[17,42,50] Seismic operations, particularly over 70 days, will result in chronic, not just temporary, impacts, leading to long-term harm to individuals and populations that depend on the proposed permit region.

3.3.9 **Disregard for Cumulative Impacts of Project Stressors** The EIA does not adequately consider the cumulative impacts of multiple noise sources, such as airguns, vessels, and ambient noise, over the duration of the 70-day seismic survey. Despite including a discussion on Cumulative Impacts (e.g., BAR section 9.2) generally, the BAR adopts a siloed approach in assessing risks Per the EIA impact assessment protocol, the criteria required to score a "High" Cumulative Impacts is stated as: "Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/ definite that the impact will result in spatial and temporal cumulative change" (BAR, Table 39). Yet there is no transparent measure assessing the interactive impact of each potential threat. Instead, the TOS appeared to assess risks in isolation rather than integrating them. For instance, there is no apparent analysis concerning the impact to species that

experience temporary hearing loss (TTS) alongside habitat displacement- and although this would change the temporal and spatial scale of impact that is not reflected in the mitigation assessment. Similarly, the combined effects of anti-predator behaviors triggered by vessel noise and physiological stress associated with seismic noise may change reproductive output in fishes, which would alter the temporal scale of impact – but this scientific probability did not appear to change the risk assessment rating. This piecemeal approach – or at the very least the lack of transparency pertaining to how cumulative impact criteria were scored – significantly underestimates the true impact of the proposed activities.

3.3.10 **Disregard for Cumulative Impacts of Possible Multiple Projects** The EIA fails to propose adequate mitigation to prevent the impact of multiple exposures to marine organisms in association with other proposed survey projects in the region (e.g., Searcher and Gx Technologies). This scenario – multiple projects occurring simultaneously – was not quantitatively modeled within the Acoustics Specialist Report, addressed in the Marine Ecology Report, and therefore adequately assessed in the EIA. The EIA within the BAR considers the impact of the proposed exploration project isolation, with one brief mention of isolated impacts of multiple project (BAR, p. 211). This is a gross oversight that requires comprehensive consideration and mitigation strategies based in realistic data to remedy.

Each additional project in or near the proposed survey region is associated with a set of risks that compound when they occur in close spatial or temporal proximity. Most mitigation measures proposed to address the impact of anthropogenic noise in the EIA would be minimized or completely invalidated by the presence of additional exploration. Part of the EIA mitigation plan hinges on there being a 'safe place' for marine organisms to retreat to avoid the impacts of extremely high amplitude sound, or by minimizing the spatial and temporal scale of sound exposure associated with the project. These assumptions are untrue if multiple project occur simultaneously. The scale of sound propagation greatly exceeds the proposed 40 km mitigation zone proposed to account for the occurrence of simultaneous projects (BAR, p. 211). Moreover, depending on the temporal scale of the other project, this would extend the overall high noise exposure to the environment, rendering the modeled SEL in the Acoustics Report incorrect, increasing the probability for both PTS and TTS for marine organisms, and increasing the probability for elevated stress levels in marine organisms at a regional level. Noting that the sound of seismic exploration, vessels, and other anthropogenic noise sources can travel for hundreds or even thousands of miles, the 40km buffer between ships would have minimal mitigation impact. No additional mitigation measures were proposed (e.g. adjusting the timing of operations, altering seasonality, stopping in the presence of other operations, etc.).

3.3.11 **Flawed Scoring System** The EIA employs a scoring system that does not allow for population-level impacts or the meaningful incorporation of uncertainty. In data-deficient situations, this scoring system biases the assessment toward assuming minimal impact, leading to underestimation of real risks. There is a need to factor in

uncertainty and variability in population responses to ensure a precautionary approach is taken.

3.3.12 **Inadequate Mitigation Zone** The EIA's reliance on a 500 m mitigation zone is insufficient to protect marine life from the harmful impacts of seismic noise. The Acoustics Specialist Report explicitly indicates that behavioral impacts are expected for marine mammals at distances up to 3.8 km from the array source and for fish at 1.3 km. Similarly, a zone of 2-5 km is necessary to avoid significant impacts on squid and other cephalopods (BAR, p. 215). A 500 m zone does not adequately mitigate the risk of injury or behavioral disruptions, especially given the repetitive use of airguns over 70 days. The BAR and associated specialist reports failed to incorporate the best available statistical methods to model habitat abandonment or avoidance, which would provide a more accurate assessment of indirect impacts[18,19,31,32]

3.3.13 **Failure to Use Best Science** The EIA fails to incorporate the best available scientific practices in its mitigation strategies. For example, in the absence of comprehensive biological surveys, best practice recommends assuming the presence of sensitive species and applying conservative mitigation measures to avoid harm. The reliance on outdated scientific recommendations from the Acoustics Specialist Report results in insufficient mitigation strategies. The Specialist Report critiques this failure to integrate the latest scientific guidelines, such as those from Southall et al. (2021), which provide more accurate frameworks for assessing long-term noise impacts (Specialist Report, p. 57).

Selected section specific comments associated with proposed mitigation within the EIA

9.3.1.1 ACOUSTIC IMPACTS OF SEISMIC SURVEYS ON MARINE FAUNA
This section outlines the importance of sound in the marine environment and the broad impacts of the noise associated with seismic operations to the marine environment and fauna. The following specific points are made (p. 128, statistics per the BAR):

1. **Shipping noise** is a significant and persistent source of anthropogenic sound, particularly at low frequencies, and can propagate over large distances, affecting vast marine areas.
2. The **Application Area** for the proposed project lies within busy shipping routes, where ambient noise is expected to be high (90-130 dB) due to shipping traffic.
3. **Seismic surveys** use intense sound sources, which can also propagate over great distances, with sound transmission being influenced by factors like water depth, distance, and ocean conditions. Sound pulses change in character due to reflective boundaries (sea surface, seafloor, etc.).
4. In **shallow waters**, seismic sound can travel up to 75 km, while in **deep water**, detection ranges can exceed 1,000 km under ideal conditions.
5. **Marine animals' auditory masking** occurs when background noise interferes with their ability to detect important environmental sounds. The duration and repetition of seismic impulses can affect animals' hearing thresholds

Despite the BAR's identification of these threats, most of these concerns are not adequately addressed by the proposed mitigation measures. Below is a point-by-point consideration of these omissions.

1. ***Shipping noise:*** *is a significant and persistent source of anthropogenic sound, particularly at low frequencies.* Despite this, the BAR neither commissioned the modeling of noise associated with the seismic ship and vessel operations, nor conducted a baseline soundscape analysis to measure the potential changes associated with seismic operations. Mitigation measures did not include vessel speed limits or daily maximum hours a day of use, both which would minimize vessel noise associated with shipping operations. The EIA within the BAR determined pre-mitigation impact of vessel noise on marine fauna to be "LOW" however, there is no empirical data to support this.

2. ***The Application Area*** *for the proposed project lies within busy shipping routes, where ambient noise is expected to be high (90-130 dB) due to shipping traffic.* TGS failed to measure the *in situ* contributions of vessel noise to the proposed permit area or the adjacent areas likely to be ensonified by seismic operations. It is not possible to test this claim, or to assess how the proposed operations will alter baseline soundscapes. In the absence of *a priori* measurements and comprehensive modeling. While vessels within an environment are loud, seismic operations including vessel operation and have been demonstrated to elevate ambient noise conditions in all known cases, and in broader frequency ranges than anticipated.[4,53–58] Per the Acoustics Specialist Report, ambient sound values will well exceed the 90-130 dB range within and beyond the permitted area in association with seismic operations (Acoustics Specialist Report, Table 11).

3. ***Seismic surveys*** *use intense sound sources, which can also propagate over great distances, with sound transmission being influenced by factors like water depth, distance, and ocean conditions. Sound pulses change in character due to reflective boundaries (sea surface, seafloor, etc.).* In keeping with this point, the Acoustic Specialist Report indicated that "the directivity of received noise is dominated by the directionality of the source array." Simply put, the direction the sound is produced in, dominates the direction the sound impacts. Despite this, no mitigation measures were suggested to restrict directionality of sound sources to minimize impact to biologically sensitive areas within and beyond the proposed permit zone.

4. ***In shallow waters,*** *seismic sound can travel up to 75 km, while in deep water, detection ranges can exceed 1,000 km under ideal conditions.* While this statistic is an underrepresentation (seismic has in certain context been detected for up to 4,000 km [4]), the BAR is correct that seismic sound can be very far reaching. Despite this acknowledgment, and the demonstration in the Acoustic Specialist Report that loud persistent sound sources associated with the proposed project are up to at least 200 km (maximum modeled distance), there were no concrete mitigation measures suggested that would minimize the acoustic energy input into the ocean throughout the project or to assess impact at a broader spatial extent.

5. ***Marine animals' auditory masking*** *occurs when background noise interferes with their ability to detect important environmental sounds. The duration and repetition of seismic impulses can affect animals' hearing thresholds.* It is true that the sound associated with seismic operations can mask critical sounds; behavioral responses also include altering the timing of calling – which may also interfere with important information transfer. Additionally (though unaccounted for in the Acoustics Specialist Report) the seismic ship and support vessels will also mask sounds. Moreover, animals experiencing temporary hearing shifts, will have altered decreased hearing sensitivities, thus increasing the likelihood and impact of masking. Despite these realities, mitigation measures do not adequately prevent the elevation of ambient sound that will lead to masking at broad scales or at altered thresholds, or indeed measure changes in the soundscape from baseline levels. Further, while the zones of behavioral response were modeled in the Acoustics Specialist Report, zones of masking were not solicited by TGS for the report.

9.3.1.1.1 NOISE IMPACT ON WHALES AND DOLPHINS

The overall assessment of seismic noise impact on cetaceans was calculated based on the impact to the individual, rather than the population, thus downplaying the potential impact to cetaceans over broader temporal scales. The proposed mitigation zone falls well below the zone of acoustic response expected for physiological, behavioral, or masking impacts. The Acoustics Specialist Report indicates that behavioral impacts are expected in cetaceans at 3.8 km from the array source. The maximum zones of temporary threshold shifts (TTS, temporary deafness) for very-high-frequency cetaceans are within 650 m of the source (Acoustics Specialist Report, p. i). Under normal operations, TTS zones for low-frequency cetaceans extend up to 5 km from the survey lines. Based on the research available and integrated into the BAR, a 500 m zone is insufficient to prevent injury to animals, especially given the repetitive use of airguns over 70 days. This strategy does not minimize harm. Similarly, because it is currently unknown how the seismic operations will elevate ambient sound (no baseline soundscape analysis was conducted) or how far the sound is expected to travel (lack of total ensonificaiton range) it is not possible to calculate the potential range over which cetaceans will experience acoustic masking. Lastly, while MMOs and PAM operators are extremely useful in mitigating negative impacts on marine mammals, many species (e.g., deep diving odontocetes) surface after long (>60 minute) dives and are extremely difficult to identify at distances greater than 1 km, thus minimizing the effectives of MMOs for long range impacts.

9.3.1.1.6 NOISE IMPACTS ON MARINE INVERTEBRATES

Despite the information contained in the Marine Ecology Report indicating the potential impact of seismic operations on marine invertebrates, and squid specifically (death, injury, displacement), and the acknowledgment that the zone of acoustic impact of for cephalopods is broad (2-5 km, BARp. 204) the BAR and its associated reports erroneously claim that impact of seismic on invertebrates is LOW (see specific comments on the Marine Ecology Report on squid). The proposed mitigation, that MMO would watch for mass squid mortality is functionally meaningless. Squid are neutrally buoyant and therefore would not float to the surface, even if squid did float, given the size of the ship, the water current associated with vessel transit, and the camouflage of the animals, mass mortalities of squid wouldn't be visible from the seismic ship.

9.3.1.1.7 NOISE IMPACT ON PLANKTON

The EIA indicates that pre-mitigation impacts on planktonic communities (the base of the marine food web) would be MEDIUM pre-mitigation. Indicating, by the TGS' admission a potentially biologically meaningful impact. Despite this the BAR states that the "Application Area is located far offshore, it is not deemed necessary to implement mitigation measures to avoid the key spring spawning periods thereby mitigating potential impacts on plankton to some degree." (BAR, p. 204). Put plainly, the mitigation plan is to do nothing; yet according to the EIA this will reduce the threat from MEDIUM to LOW. This is unreasonable, and not based in science.

9.3.1.2.1 IMPACTS OF NON-SEISMIC NOISE (VESSEL AND HELICOPTER NOISE)

The significance of non-seismic noise is said to be "low" before and after mitigation. This cannot be assessed according to the BAR's own criteria in the absence of a baseline soundscape analysis. Vessel noise, particularly as it reaches CBAs, MPAs, and regions of ecological importance (seamounts and caverns containing deep water corals), will alter the soundscape in potentially meaningful ways. This could impact larval recruitment, predator-prey dynamics, and beyond. The EIA, and the reports it relied on for assessment, failed to quantify, model, or predict, elevated ambient noise associated with vessel or aircraft within or beyond the proposed permit area. The assumption that this noise does not meaningfully impact the environment cannot be assessed. No mitigation was suggested, this course of action is not based on scientific information.

4 SUGGESTIONS FOR REASSESSMENT OF NOISE IMPACTS

NOTE This is a **minimal** selection of suggested assessment and mitigation measures pertaining to acoustics impacts associated with the proposed seismic operations. These measures alone will not be sufficient to minimize the acoustic impact to the marine environment within and beyond the proposed permit region. These suggestions are needed in order to assess if or how to develop mitigation plans to minimize acoustic impacts..

1. **Comprehensive Soundscape Analysis (1-Year Minimum) Prior to Project Implementation**
   Objective: Conduct a thorough baseline analysis of the soundscape within the habitat over a minimum of one year before project activities begin. This will help establish a baseline understanding of natural noise levels and seasonal variations, providing critical context for assessing the potential impact of the project's noise on the ecosystem.

2. **Model Full Spatial and Temporal Range of Ensonification for All Sound Sources**
   Objective: Model the full spatial and temporal extent to which anthropogenic sounds associated with the proposed project will inundate marine soundscapes, including the ensonification range for airgun operations within the proposed permit area, as well as the ensonification associated with seismic ship and support vessel transit within and beyond the proposed permit area.

3. **Inclusion and Consideration Population Level Impacts and Associated Uncertainty**
   Objective: Acknowledge the necessity of modeling population level impacts (including estimated proportion impacted) and incorporate uncertainty in population density

estimates for the relevant species (e.g., marine mammals, fish, etc.) by developing multiple density scenarios. This includes:

a. Assessing the risk to species under a range of plausible population densities, especially considering variability in population numbers.
b. Where available, use population abundance data and apply variability factors to estimate the proportion of the population that could be exposed to noise during the project's operational period (e.g., 70 days).

4. **Separate Mitigation for Direct (Injury) and Indirect (Behavioral) Impacts of Noise**
Objective: Differentiate between the direct impacts (e.g., physical injury) and indirect impacts (e.g., behavioral disturbances) of noise exposure on species and propose mitigation for each
   a. **For direct impacts,** model potential injury thresholds based on noise exposure.
   b. **For indirect impacts,** consider the latest version of the **probabilistic disturbance approach,** which incorporates various behavioral states (e.g., feeding, resting, migrating) and estimates the time spent in each state. This method will help refine understanding of how noise affects species' daily activities.
   c. Develop mitigation relevant to spatial and temporal ranges of each.

5. **Exposure and Risk Assessment Based on Behavioral States**
Objective: Rather than adopting a blanket seasonal approach, model exposure levels and risks based on species' behavioral states (e.g., breeding, feeding, migration) and proportion of the population engaged in each activity. This will allow for the development of an **operation schedule** that minimizes noise during critical behavioral periods, thus reducing potential disruptions.
   a. The model should take into account how noise influences different states, adjusting operations to align with periods when species are least sensitive to noise.

6. **Integration of Southall et al (2024) Recommendations**
Objective: Implement the recommendations outlined by Southall et al. (2024) on managing anthropogenic noise. The study critiques current regulatory approaches adopted in the BAR which rely on simple thresholds for noise exposure criterion. Southall et al (2024) calls for more nuanced criteria that consider species-specific and context-dependent responses, including behavioral responses.

7. **Required Evaluation of Proposed Mitigation Measures**
Objective: Evaluate the effectiveness of proposed mitigation strategies for both direct and indirect impacts that include uncertainty. This should involve a **comparative analysis** of different mitigation approaches, such as noise reduction technologies, spatial or temporal restrictions, and habitat protection measures. The evaluation should include:
   a. Quantitative and qualitative assessments of the potential success of each measure.
   b. A comparison of the potential impacts before and after the implementation of mitigation measures.

c. Consideration of adaptive management approaches based on scientifically based zones of impact to allow for adjustments if initial mitigation measures prove inadequate.

8. **Incorporation of Real-World Detection Probabilities of Marine Mammal Observers into Risk Assessment and Mitigation Strategies**
Objective: Integrate **real-world detection probabilities** of Marine Mammal Observers (MMOs) into the risk assessment process and the development of mitigation strategies. These detection probabilities can vary significantly based on factors such as:
   a. **Species size** (larger species are easier to detect)
   b. **Group size** (larger groups are more noticeable)
   c. **Time of day** (e.g., detection can be lower during low light conditions such as dawn, dusk, or night)
   d. **Observer experience** (more experienced observers are likely to have higher detection success)
   e. **Animal behavior state** (for example, animals in more active states may be easier to spot than those resting or submerged)
   f. This incorporation will help **refine risk assessments** by accounting for the inherent variability in detection rates and potential missed detections, especially during times of high operational noise or challenging environmental conditions. Additionally, it ensures that mitigation measures (such as shutdowns or noise reduction) are based on more realistic expectations of detection success, thereby improving overall protection for marine mammals.

IN THE HIGH COURT OF SOUTH AFRICA

(WESTERN CAPE DIVISION, CAPE TOWN)

Case No ...../2024

In the matter between:

AUKOTOWA FISHERIES PRIMARY CO-OPERATIVE LIMITED	First Applicant
THE GREEN CONNECTION NPC	Second Applicant
NATURAL JUSTICE	Third Applicant

and

DIRECTOR-GENERAL: DEPARTMENT OF MINERAL AND PETROLEUM RESOURCES	First Respondent
MINISTER OF ENVIRONMENTAL AFFAIRS	Second Respondent
TGS GEOPHYSICAL COMPANY (UK) LTD	Third Respondent
MINISTER OF MINERAL AND PETROLEUM RESOURCES	Fourth Respondent

---

EXPERT AFFIDAVIT : G K HAMILTON

I, the undersigned,

GILLIAN KAY HAMILTON

do hereby make oath and state:

1. I am an economist specializing in climate change, particularly in climate mitigation, energy, and development economics.

2. The facts contained in this affidavit fall within my personal knowledge, except where I indicate otherwise and are, to the best of my knowledge, true and correct. To the extent that I rely on information supplied by others, I believe that such information is true and correct.

3. I hold a Master's degree in Sustainable Development from Stellenbosch University, a BPhil (Honours) in Sustainable Development from Stellenbosch University, an Honours in Economics specializing in trade and development from the University of Johannesburg, a Postgraduate Diploma in Management from Wits Business School, and a BCom from Pretoria University.

4. With over 20 years of experience, I have conducted extensive research and identified solutions to developmental challenges in South Africa, including economic models of development. As the former Branch Manager for Al Gore's NGO in Africa, the African Climate Reality Project, I possess comprehensive knowledge of climate change and climate mitigation policies. In this capacity, I represented civil society in discussions on various climate mitigation and economic policies in South Africa, including the carbon tax regulations and the green taxonomy.

5. In 2021, I authored a literature review titled "The Socioeconomic Consequences of Offshore Oil and Gas Activities on South Africa" for The Green Connection. I presented my findings at the African Oceans Tribunal and to the Energy Governance Network of South Africa. I have also published several opinion pieces advocating for sustainable economic practices, such as

"The GNU must come to grips with energy transition" and "Gas is a risky investment for SA amid renewables push."

6. My experience and qualifications are set out in my curriculum vitae, a copy of which is attached marked Annexure **"GH1"**. By virtue of my qualifications, training and experience, I submit that I am qualified to give expert evidence on the issues traversed in this affidavit.

7. In order to arrive at a balanced assessment of whether or not the 3rd Respondent's proposed offshore 3D seismic survey (a technology used for the acquisition of seismic data for possible future oil and gas exploration) is socially, environmentally and economically sustainable, it is necessary to assess, evaluate and consider the social, environmental and economic impacts (and risks) of those activities, both positive and negative.

8. In the 2nd Respondent's Appeal Decision, it is recorded that the 1st Respondent indicates that "...It is also important to note that the proposed project has the potential to produce long-term benefits to South Africa, even though immediate benefits are limited..." (at para 2.9.3) and "...Whilst there are no immediate benefits from the proposed activity, however, dependent on the success of the proposed project, there might be future benefits" (at para 2.9.8).

9. The 2nd Respondent notes in her evaluation (reasons for decision) that "...some of the concerns raised by the Appellants extend beyond the proposed project activity in respect of which the EA was granted. I confirm that any activity beyond the EA will be subject to a separate application and a separate assessment process. Accordingly, it is not necessary to consider submissions made in respect of activities that fall outside the EA for the purposes of this

appeal" (para 2.21.2). The 2nd Respondent indicates further she is "...satisfied that the socio-economic impacts and mitigation measure on *inter alia*, marine fauna, small scale and commercial fishing have been considered and assessed..." (at para 2.21.6) and that "Many of the comments made by the appellants were made on the assumption that the impacts associated with production had to be considered, not just those associated with exploration. This approach is incorrect. The EA and accordingly, this appeal is limited to considerations of the impacts of exploration which are far less significant and far less invasive than they will be if extraction and production takes place. As such, it is not necessary to consider the possible impacts of a project that is not yet planned and falls outside the scope of the EA" (at para 2.21.7).

10. As a consequence, the potential negative economic impacts and risks of developing an oil and gas sector in South Africa have not been assessed, evaluated or considered.

11. In this affidavit, I explain the potential negative economic impacts and risks of developing an oil and gas sector in South Africa, based on an extensive literature review and research. The views expressed in this affidavit are dealt in more detail in the Addendum '***Literature Review: The Negative Economic Impacts of Developing an Oil and Gas Sector in South Africa***' (**Annexure "GH2"**).

12. In Summary, the research shows (among other things) that:

12.1. The disparity between the narratives of African leaders and the realities faced by communities in sacrifice zones (A sacrifice zone refers to a geographic area that has been permanently impaired by environmental

damage or economic disinvestment) illustrates a fundamental misunderstanding of the adverse effects fossil fuel investments can have on local economies.

12.2. Research shows that establishing an offshore oil and gas industry within South Africa is unlikely to yield significant economic benefits. Instead, it may exacerbate existing challenges. Past experiences across Sub-Saharan Africa indicate that actual benefits often fall short of forecasts.

12.3. With an accelerated global energy transition through increased shifts towards renewable energy and increasing climate mitigation commitments, the risks associated with oil and gas developments are profound. The financial, environmental, and social repercussions may well outweigh any anticipated economic gains in the form of increased levels of sovereign debt, lower credit ratings

12.4. It is imperative for South Africa to adopt a sustainable and renewable energy-focused economic approach, acknowledging the importance of protecting the socio-economic well-being of its citizens and environment.

Differentiating between Economic impacts during the reconnaissance (3D seismic survey), exploration and extraction phases

13. The economic impacts on South Africa of developing an oil and gas sector will differ during the reconnaissance (3D seismic survey), exploration and extraction phases:

- During the reconnaissance phase (3D seismic survey), the impacts are likely to be short term in duration (due to the surveys estimated to take no more than 70 days). However, if these surveys have a negative impact on the fish stocks and the fishing industry then there are likely to be long-term, negative ramifications in the longer term on the local economy.[1]
- During the exploratory phase, the impacts are likely to be largely localised and positive, albeit, of a relatively short-term duration (likely around six months) and smaller in magnitude. This assumes there won't be negative impacts on the fishing industry which will have extensive longer-term impacts on the local primary, secondary and tertiary industries reliant on fish stocks.
- During the extraction phase, the impacts are likely to be negative both at a national and local level. Moreover, these impacts will have large, long-term consequences.

14. The reconnaissance (3D seismic survey) phase will likely require local service providers for refuelling, catering as well as transport and accommodation for crew members i.e. a small, positive impact.

15. The exploratory phase will likely require local service providers for refuelling, catering, goods as well as transport and accommodation for crew changes –

[1] For instance, the research on Saldanha Bay Municipality 'Socio-Economic Futures' notes that in Saldanha Bay Municipality (SBM), 'Livelihoods in the area are heavily dependent on fishing and, to a less extent, agriculture. Fishing accounts for 31% of all jobs, agriculture 6% and food processing, which is predominately fish processing, a further 5%.' The research adds that '..while the 'financial, insurance and business services' sector is large it only exists because of the income generated from fishing, 'food, beverages and tobacco' and construction.' Fishing is the most important economic sector in Saldanha Bay Municipality, at 15% of the total value added in the SBM. The report concludes that the local municipal area is overwhelmingly dependent on fishing and fish processing as nearly all the tertiary industries are a product of these industries. A downturn in these sectors will largely increase unemployment, poverty and inequality at a local scale.

with impacts more similar to tourism. This is due to the specialised nature of the survey vessels and drilling unit which are sourced from international contractors. The technical nature of the operations means that the survey vessels and drilling unit are crewed by highly skilled and experienced personnel largely recruited internationally.

16. The extraction phase could last for decades and during this time, South Africa's 'resource curse' (explained below) is likely to be magnified, and experience both in South Africa and internationally has indicated extensive negative local economic development, essentially maldevelopment.

Experience from other African Countries

17. Lessons learnt from other African countries indicates that there are numerous challenges that arise between the reconnaissance (3D seismic survey) and exploration phase and the actual production, and that these have economic consequences that must be taken into account:

- **Overvaluation of oil and gas finds**: For oil and gas to be commercially viable, the deposit size of the find is important. Many oil and gas finds in Africa tend to be overestimated due to companies wanting to emphasize positive results to inflate their share prices. This misled governments and other companies exploring in the same areas.
- **Timeline from discovery to production**: Oil and gas projects frequently have time and cost overruns, especially in Africa. Globally, the average amount of time it takes to get from discovery to production is 7.5 years. In Sub-Saharan Africa, the average time is around 12 years. For gas assets, the average time is 9 years globally, versus 15 years in Africa. The

extensive time and cost overruns may make these extractive projects less commercially viable.

- **Government revenues generated tend to fall significantly short of forecasts**: Revenue projection is on average 63% lower than is initially estimated. The shortfall has been attributed to lower rates of production than originally forecast; challenges associated with taxing production as the resource sector can be hard to tax effectively; underestimates of costs or cost deduction; and, mistaken fiscal assumptions in modelling. Consequently, the share of after-cost revenues that flow to the government as opposed to companies (known as the 'government take') is lower than initial expectations.

18. Senegal and Mozambique are recent examples of countries that have faced these challenges. Senegal's oil and gas sector has faced project delays, political uncertainties, mismanagement while their domestic energy poverty has not declined. Mozambique estimated that Area 1 and Area 4 within the Rovuma Basin would earn between $31 and $63 billion in government take over the lives of the two projects, with the likely figure (its base case scenario) being in the region of $49 billion. However, these revenues are significantly overstated and modelling undertaken in 2021 indicates that revenues are likely to be in the region of $18.4 billion, 70% of which will only come after 2040.

The Resource Curse and Localised Maldevelopment

19. The resource curse, also known as the 'Paradox of Plenty' refers to the failure of states to improve the social and economic conditions of their citizens despite being rich in resources such as oil and gas. In addition, countries rich in

extractive resources tend to have higher levels of inequality and lower levels of democracy. South Africa already suffers from the resource curse, experiencing many of the symptoms outlined in the resource curse literature. These symptoms include relatively slow GDP growth, gross inequality and entrenched poverty. Most of the SA population has failed to benefit from natural resource wealth – with sections of society actively harmed through the process of mineral extraction.

20. There is an assumption that the establishment of an oil and gas industry brings extensive local economic benefits to the areas in which the industry takes hold. International experience indicates that regions rich in non-renewable resources have tended to be cursed, rather than blessed and tend to suffer from localised maldevelopment. For example, evidence from the United States and Canada shows that the influx of people that follows the emergence of extractive industries results in increased demand for public services for several complex and often interrelated reasons. A growing population clearly demands increased infrastructural support in terms of basic municipal services such as health, education, emergency services, water and sanitation, electricity, and transport.

21. The influx of people to local areas also has other negative social ills or consequences such as:

- Increases in prostitution.
- Sex trafficking, including children, in oil boomtowns linked to 'a confluence of underlying forces including big oil money, an increase in drug cartels

and drug use, degradation of women in a male-dominated workforce, increased access to weapons, and a rise in transient populations'.

- Increases in domestic violence, dating violence, sexual assault, and sexually transmitted diseases.
- Increases in traffic violations, traffic accidents and fatalities.
- Increased drug abuse and drug trafficking.
- Crime levels increase compared to before the extraction of oil and gas and compared to other towns without extractive industries.
- Unemployment levels in these towns tends to increase.

22. An excellent example of the resource curse and local maldevelopment in South Africa is the platinum boom in Rustenburg. Between 1994 – 2009, platinum output increased by 67% between 1994 and 2009, changing Rustenburg from an agricultural community to city. By 2012, Rustenburg contributed almost 5% to South Africa's GDP. During this period, people migrated to Rustenburg to find jobs in the platinum sector which resulted in the population growing from about 68 000 in 1996 to 626 522 in the 2016. The most significant increase was among the male population in the 20 – 34 age group. However, the impact of the platinum boom has been largely negative.

23. The rapid increase in population density has led to numerous social challenges, including increased unemployment rates, increased crime rates (and frequently noted as the most dangerous city in Africa), substantial increases in HIV and AIDS rates, and significant poverty levels and income inequality threaten social cohesion as almost 62% of the population live in poverty. Evidence shows that the local government is unable to meet the demand for basic services such as housing, water, electricity, sewerage, public transport, health facilities and

schools. This inability to meet with the demands for social goods has been hampered by the mismanagement of local public finances, inadequate government capacity, and questionable policy decisions.

The Reduction in Demand for Fossil Fuels and Transition Risk

24. It is widely agreed that the world is currently transitioning its energy sources from fossil fuels to clean energy. A number of global energy scenarios forecast a global decline in oil and gas use (some from as early as the 2020s) although the pace and scale of the transition differ amongst scenarios. The drivers responsible for these differences range from the implementation of stronger climate-friendly policies, improvements in technology, increasing energy efficiency and the cost competitiveness of oil substitutes amongst other factors. Mass-manufactured technologies such as solar photovoltaic (PV), wind turbines and electrical vehicles (EVs) are leading the way. Sales of residential heat pumps and stationary battery storage are also rising. At the same time, implementation and updating of government policies and the slowdown of China's growth rate are expected to continue to drive the global energy transition.

25. Transition risk is the risk that the value of assets and income are less than expected because of climate policy and market transformations, such as the transition away from fossil fuels i.e. a reduction in demand. Modelling indicates that both current and emerging African petrostates should be cautious when considering investing in gas and gas infrastructure because investments in African gas are ultimately value destructive. Notably, this declining demand is important for new oil and gas projects to take into account when considering

the economic, financial and climate change risks of major new oil and gas projects.

26. If South Africa plans on exporting oil and gas, as a newcomer to the market, its costs would likely be higher than established players and due to the global transition to net zero, South African gas will not be sufficiently price competitive to be exported or there will be no market for South African oil and gas. If the intention is to use the oil and gas domestically, then models developed in South Africa indicate that South Africa's power needs can be met with very little gas and the large majority of new energy new generation capacity should be wind and solar, with an increasing requirement for flexible (dispatchable) capacity to support this. Moreover, gas power is almost triple the cost of renewable energy and thus not cost-competitive. Research by National Business Institute (NBI) indicates that either way South Africa will have to substitute gas with greener alternatives and phased out by 2050 for South Africa to achieve a net-zero 2050 target. This indicates a high probability of stranded assets if South Africa invests in both the upstream and downstream oil and gas sector.

The Risk of Stranded Assets

27. **Stranded assets** are assets that become devalued or fail to generate an economic return before the end of their economic lifetime or can no longer be monetised due to changes in circumstances. Simply put, stranded assets are projects that fail to deliver adequate returns as conditions change. Economic modelling shows that to achieve Net Zero Emissions in 2050 (NZE2050), with the current levels of investment in oil and gas, over US$350 billion in African oil

and gas assets would be stranded, with more than US$90.3 billion in stranded assets in Nigeria alone. The implication for South Africa is that it is likely that investments in an oil and gas industry will end up being stranded assets as the demand from fossil fuels falls and the energy transition gains momentum.

Fiscal Breakeven Price

28. The fiscal breakeven price or price necessary for an oil-exporting state to balance its budget is another way to measure a state's vulnerability or economic resilience. Although oil and gas producers do not know what demand and price will do in the future, it is likely that an early excess of supply is likely to push down prices, leading to low subsequent investments, and resulting in higher prices in the short term.

29. Essentially, the lower the production price is for a state, the less vulnerable these states are – it is important that a petrostate's fiscal breakeven price is higher than the average price of Brent crude oil (approximately USD 80 per barrel in 2023). Therefore, only those petrostates that have reduced costs and carbon intensity and become aggressively competitive will be viable as overall demand and markets become more competitive during the energy transition. The Global Energy Scenarios forecasts that in the Net Zero Emissions scenario oil will be around $15 per barrel and the Mean scenario forecast oil price at around $65 per barrel from 2027 to 2050. At this stage, few petrostates will have a breakeven fiscal price i.e. their costs are not profitable. As an emerging Petrostate, South Africa's investments in an oil and gas sector are unlikely to be low enough to breakeven, never mind be profitable.

Additional Economic Risks and Decreased Macroeconomic Stability to be

Considered

30. The anticipated negative economic impacts (external costs) of developing a domestic offshore oil and gas sector at this juncture include, but are not necessarily limited to, the social costs of carbon, increasing sovereign debt and fiscal risk, a downgrade in our credit ratings (making capital more expensive), an increase in illicit financial flows and a reduction in our trade and competitiveness. These factors are likely to decrease South Africa's macroeconomic stability.

Increase in Sovereign Debt

31. The increase in sovereign debt levels in low- and middle-income countries is not only attributed to oil and gas dependency however **oil and gas production tends to exacerbate fiscal risks.** Petrostates tend to become locked into debt dependency because they tend to have increased fiscal dependence on oil and gas revenue, increasing their debt levels when the oil price is high because their credit ratings rise and hence make cheaper finance available, **and when it is low,** in order to fill their resulting fiscal gaps. It is likely that **the energy transition will further exacerbate the levels of sovereign debt** as countries credit ratings decline and debt becomes more expensive while also seeing revenue from oil and gas falling and debt servicing becoming more important.

32. South Africa's debt has ballooned and is expected to increase to 77.7% of GDP in the 2025/26 fiscal year. This limits government's ability to channel resources into the productive side of the economy as debt service costs are crowding out social spending as debt repayments form a greater share than social protection, health, community development, or economic development, with one in every

five rands being spent on servicing the debt. However, if SA has to take out further loans to develop an O&G sector, our debt and debt repayments would rise even more which could lead us to default on debt repayments and to shift into a full economic recession. If the oil and gas sector cannot deliver on increasing economic growth, as predicted with the increase in transition risk, it is questionable whether it is prudent to be investing in volatile commodities like oil and gas which could become a serious financial burden on the South African economy.

Downgrade in credit ratings

33. Credit ratings are described as **independent mechanisms to assess creditworthiness** or the ability – and willingness – **of debt issuers to meet repayment**. Credit ratings provide international investors with a rapid, standardised way to assess and price debt, and are particularly important for borrowing in international capital markets.

34. Although **fossil fuels** were once considered to be credit positive, credit ratings agencies now issue **specific warnings about the financial risks of fossil fuels** including oil and gas as these now face substantial financial risks. There has already been a trend emerging of petrostates' credit rates being downgraded. As petrostates earn less revenue from their oil and gas production, their **creditworthiness declines** i.e. they will have **lower credit ratings and thus borrowing on international capital markets will become more expensive** for these petrostates. The consequences are likely to be a devaluation of currency, rising debt levels, reduced access to capital markets and economic contraction leading to lower investor confidence.

35. South Africa's credit ratings have been somewhat volatile over the last decade and these ratings are lower than investment grade ratings, making it more expensive to borrow on international markets. It is likely that investment in the O&G sector in SA would result in credit ratings agencies further downgrading us, making it more challenging to borrow on international markets.

Increase in Illicit Financial Flows

36. **Illicit financial flows** (IFFs) are methods, practices and crimes aimed at **transferring financial capital out of a country, in contravention of laws.** IFFs include money laundering, bribery and tax evasion. Research indicates that the **extractive industries, like the oil and gas sector, are particularly prone to IFFs.** Illicit financial flows (IFFs) are difficult to measure due to their secrecy but it has been estimated that South Africa is losing more than $62 billion a year because of illicit financial flows and tax evasion. It is likely that IFFs will take place in an oil and gas sector in South Africa where it is difficult to govern and measure extraction of oil and gas – which further impacts on the lack of profitability of an oil and gas sector and will reduce government take.

Decrease in trade and competitiveness

37. There has been an increasing focus on **climate measures to prevent the risk of carbon leakage** (i.e. the movement of production and associated emissions between countries due to different levels of decarbonisation effort through carbon pricing and climate regulation) and is designed to **support increased ambition on climate mitigation**. These are known as carbon border adjustment mechanisms (CBAMs) or taxes. However, South Africa's exports

are at particular risk and South Africa is vulnerable to changes in trade patterns arising from measures aimed at transiting to low-carbon pathways.

38. South Africa's exports are already very carbon intensive due to our carbon-intensive energy system and the country is a large exporter of fossil fuels. And as South Africa has a relatively long distance to its trading partners, this has implications for transport costs and associated greenhouse gas (GHG) emissions. The impact of CBAMs will be determined by the carbon embedded production in goods that are traded. Analysis by TIPS notes that under the EU CBAM, a total of US$2.4 billion (about R45.4 billion) of South African exports (based on 2023 data) is at risk in the short term. The UK CBAM would have a smaller impact but would likely result in a total of US$223 million (About R4.3 billion) of South African exports (based on 2023 data) being at risk in the short term.

39. Thus, if South Africa decarbonises its electricity systems more, the CBAMs will have less impact. However, if South Africa chooses to invest in an oil and gas sector, this will increase its carbon emissions and exports will be negatively impacted through these CBAMs, with substantial negative impacts on our Gross Domestic Product (GDP) and on employment.

Increase in the social costs of carbon

40. The social cost of carbon (SCC) is an estimate of the cost of the damage done by each additional ton of carbon emissions. It also is an estimate of the benefit of any action taken to reduce a ton of carbon emissions. Research estimates that the macroeconomic damages from climate change are six times larger than previously thought. The social cost of fossil fuel combustion for South Africa is

at least R660-billion a year and exceeds, by five times, the revenues government earns from fossil fuel combustion. The social cost includes deaths, disease and working days lost owing to air pollution and GHG emissions.

Decommissioning Costs Must be Factored into Economic Calculations

41. It is important to include the cost of decommissioning of offshore oil and gas infrastructure upfront in all financial decisions – otherwise these costs will be borne by the state and ultimately, by the South African taxpayers. For instance, the total cost of decommissioning UK offshore oil and gas production, transportation and processing infrastructure is estimated to cost £48bn. At present, there is no estimation of what decommissioning of oil and gas infrastructure costs will be for South Africa but these costs must be included in economic models.

Most likely economic scenario for South Africa's oil and gas sector

42. Based on the logic from other African countries, if South Africa were to find oil or gas in 2024, it would likely take at least until 2034 to start producing (but more likely in 2039) – and then South Africa would have a payback period of approximately 15 years (i.e. until 2049 or 2054) before the country would begin to see any profits on these investments. However, South Africa will need to shut operations due to climate change commitments by 2050 (if the global market for oil and gas even exists at that stage, which from the energy scenarios, seems unlikely).

43. During this time, South Africa is unlikely to see fiscal benefits such as increases in economic growth.

44. From a macroeconomic perspective if South Africa pursues an extractive oil and gas policy, it is likely that South Africa's levels of debt will increase and credit ratings are likely to drop further and due to the presource curse, these negative macroeconomic impacts are likely to take place before production begins, amplifying the knock-effect of poor decision-making.

GILLIAN KAY HAMILTON

I hereby certify that the deponent knows and understands the contents of this affidavit and that it is to the best of her knowledge both true and correct. This affidavit was signed and sworn to before me at Johannesburg on this the 11 day of November 2024, and that the Regulations contained in Government Notice R.1258 of 21 July 1972, as amended, have been complied with.

Sustainability, Climate Change Consultant, Analyst, Advisor

EXPERIENCED **sustainability and climate change consultant – leveraging a business and economics background and extensive experience in 'making order from chaos', developing strategy, plans, solutions.**

- 20 years' immersion in Development, Sustainability, Climate Change
- Former Head Africa Climate Reality Project (Al Gore's NPO)
- GIZ Climate Change and Climate Leader (Al Gore) trained
- BPhil *cum laude*, MPhil Sustainable Development (Stell)
- BCom, BCom Hons Economics, PD Management (Wits)

work experience

Principal Consultant – Sustainability, Climate Change

Twig Consulting | Johannesburg, South Africa | 2010 - present

LEAD **development of research, policy, strategy, projects, project evaluations, analysis, case studies and reports for public and private organizations (eg UNICEF, the DTI, InfraSalience, Trialogue and GIBS.) Research, analyse data, write reports on the impact of climate change in Africa and on South Africa's energy and climate policies.**

➢ *Key Areas of Focus:* **Sustainability; Climate Change; Climate Diplomacy; Alternative Economics; Green Finance; Biodiversity; Energy Policy; Politics; Economics**

➢ *Key Projects, Contributions, Outputs:*

- **Lead** a network of African climate experts working on aspects of climate diplomacy.
- **Spearheaded research for NGOs and present** reports to, network with and connect NGO, government and other stakeholders (eg forums such as the SA Oceans Tribunal). Notable research includes making the case for the South Africa's oceans to be declared as sentient beings.
- **Researched and developed** work on the alternative economics front – prepared a proposal ("Koeksister") outlining changes to the economic system as the basis for confronting climate and environmental changes.
- **As a Climate Leader** engage with, contribute to and participate in networks such as: EGSA and The Reilient40, developing ideas, sharing knowledge and up-to-date climate information.
- **Developed an Urban Management Strategy** for Johannesburg's Urban Forest (Food & Trees for Africa).
- **Conducted Monitoring & Evaluation** on Corporate Social Responsibility projects for Trialogue and the British Foreign Office.

- **Wrote Sustainability case studies** for GIBS (Gordon Institute of Business Science), including a study on Transnet's Biodiversity.
- **Produced research** on Agricultural Cooperatives for the DTI (Department of Trade & Industry).
- **Provided strategy and reports** for UNICEF and assisted CARE South Africa-Lesotho with their strategic planning.

Head: Africa (Programme Manager / Branch Manager)

Climate Reality Project ; Johannesburg, South Africa | May 2016 - Aug 2019

(Climate Reality Project is Al Gore's NPO. See www.climaterealityproject.org)

HEADED support to 600 Climate Leaders throughout Africa, driving achievement of objectives such as increasing influence on policy and project managing and reporting on the NPO's activities in Africa.

➢ *Key Areas of Focus:* Climate Change; Environmental Governance

➢ *Key Projects, Contributions, Outputs:*

- **Took over a local Africa office** that was having little impact and lacked credibility. With the team, consolidated, reinvigorated the vision and mission, put together exciting projects with other NGOs, and attracted additional funding for capacity building and projects.
- **Led a successful initiative** to pressure a public finance institution to reduce the funding of fossil fuels; and raised the profile of the NGO through extensive public and media commentary.
- **Successfully engaged** with the Dept of Environment to get the NEVA Study on jobs affected by climate change to be conducted.

work experience: 1998 - 2010

Project Manager | Non-Clinical Director

ECHO (Enhancing Children's HIV Outcomes) | Sept 2006 - Dec 2009

PROMOTED to Non-Clinical Director in 2007. Managed >R50m in donor funding, 100 staff and managed relationships with USAID and UNICEF. Started out managing the Hamet Shezi Children's Clinic (2006).

Early Career and Student Work:

- Independent Consultant (Development) | 2005 – 2006
- Au-Pair | 2000 - 2001
- HR Administrator | Standard Bank | 2000
- Student Work (Part-time) | 1999 – 2000
- Second Lieutenant | SANDF | 1998

1. Introduction

The landscape of energy production and consumption in Africa, particularly in South Africa, is at a critical juncture. While African leaders and elites often advocate for investment in oil and gas as a means of catalysing economic development, this perspective starkly contrasts with the realities faced by individuals residing in so-called sacrifice zones—communities impacted directly by the fossil fuel industry.

Activists, climate campaigners, and many politicians recognize the detrimental economic and environmental implications of fossil fuel dependency, arguing for a transformative shift towards sustainable energy solutions. In light of climate science and the evolving global energy landscape, the African continent is poised to either replicate the carbon-intensive pathways of the past or forge a new, cleaner trajectory.

This literature review critically examines the potential economic consequences of pursuing oil and gas investments in South Africa against the backdrop of an impending global energy transition, climate risks, and socio-economic disparities. It highlights existing narratives, emerging scenarios, and pressing challenges while ultimately arguing for an urgent pivot to renewable energy sources that can foster economic resilience and equity.

2. Global Energy Scenarios

> *The large deviations in outcome indicate a high level of uncertainty*. (RystadEnergy 2024)

The International Energy Agency (IEA) noted in their World Energy Outlook (2023) that global energy demand increased by 1.3% in 2022 and it is likely that energy demand will continue to grow. This increase in global demand for energy is due to both a growing economy and population growth (International Energy Agency 2023). Moreover, in Africa, increasing urbanisation and industrialisation will drive an increasing energy demand (Cilliers 2023).

With the increasing demand for energy in mind, the IEA (2023) developed three main scenarios to explore different pathways for the energy sector until 2050. These scenarios largely reflect government energy and climate-related policies, investment decisions, household and industrial strategies that affect the rate at which different technologies might enter the mix (International Energy Agency 2023). The IEA (2023) warns that none

of the scenarios should be considered a forecast- rather the aim is to understand the levers and likely outcomes of different actions.

In addition to the IEA (2023) scenarios, the Organization of the Petroleum Exporting Countries (OPEC) and RystadEnergy, an energy research and business intelligence company headquartered in Norway, also conducted analysis global demand scenarios for oil and gas to quantify risk and resilience (RystadEnergy 2024, Prince, et al. 2023). Both OPEC and RystadEnergy tend to have a more bullish view of the future of demand and commodity prices, however, RystadEnergy notes the high levels of uncertainty and a fast-changing market landscape which require an evaluation of the potential future risks and opportunities in the energy market (RystadEnergy 2024, Prince, et al. 2023, International Energy Agency 2023).

Prince et al (2023) note that most authoritative sources forecast oil and gas demand falling quickly as renewables capture market share but many oil companies – both private and National Oil Companies (NOCs) – are basing their investment decisions on continued or even rising levels of demand and equivalently high commodity prices. Six of the seven scenarios touched on in the literature below forecast demand for fossil fuels declining. The exception is the OPEC forecast which indicates demand for fossil fuels will increase. Each scenario is aligned to a likely global temperature rise above pre industrial levels in 2100, which is an important indication of the impact of energy on climate change.

The scenarios are:

- **Net Zero Emissions by 2050 (NZE) Scenario (1.5 °C):** In addition to keeping the 1.5 °C Goal in reach, the NZE Scenario meets UN Sustainable Development Goals (SDGs) seven i.e. universal access to reliable modern energy services is reached by 2030, and major improvements in air quality are secured. The goal of achieving the NZE Scenario is difficult but possible due to the recent acceleration in clean energy transitions. In this scenario, both behaviour changes and increases in low-emission liquid fuels results in oil demand peaking at 100 million bpd in 2023 and falling sharply to 29 million bpd in 2050. This scenario sees major changes in the composition of product demand, requiring refiners to adapt refinery configurations and business models and to invest more heavily in emission reductions, hydrogen, and biofuels.

- **RystadEnergy –Sigma Scenario (1.6°C):** RystadEnergy (2024) believes this scenario is less likely than their average scenario. In this scenario, oil demand peaks at 105 million bpd in 2025 and then declines to 39 million bpd by 2050; while gas demand peaks at 4.3 trillion cubic metres in 2030 and declines to 1.9 trillion cubic metres in 2050. Assumptions of this scenario include substantial

uptake of electric vehicles (EVs) and governments adopt policies to curtail ICE sales; banning of single use plastic and plastic recycling rates are high for some plastics types; oil substitution notably accelerates with exponential growth of sustainable aviation fuels (SAF) and changes in the maritime sector. At the same time, Asia solely drives gas demand growth in the next 10+ years and gas demand peaks in all other continents in the 2020s; gas demand for power declines through electrification of industrial and residential use intensifies from the early 2030s, supported by strong growth in renewables.

- **Announced Pledges Scenario (APS)** (1.7 °C): This scenario assumes that governments will meet, in full and on time, all of the climate-related commitments that they have announced, including longer term net zero emissions targets and pledges in Nationally Determined Contributions (NDCs), as well as commitments in related areas such as energy access. Pledges made by businesses and other stakeholders are also taken into account where they add to the ambition set out by governments. However, IEA (2023) expresses some optimism about this scenario but says that very considerable progress would have to be made for it to be achieved. Key assumptions about this scenario are that action is taken to increase the use of alternative fuels and cut emissions to achieve the climate goals of governments and targets set by industry organisations. Under the APS scenario, renewables generate approximately half of all electricity by 2030. Oil demand peaks within five years, primarily driven by the early uptake of EVs. Since it factors in the snowballing economic impacts of renewables alongside a 'forceful policy response', this is our proxy for reduced demand and declining commodity prices. This scenario's trajectory leads to 1.8°C of warming by 2100. We refer to this scenario as a moderate transition. (Prince, et al. 2023)

- **RystadEnergy Mean Scenario (1.9°C):** In this scenario, gas demand peaks at 4.7 trillion cubic metres in 2033 and declines to 3.4 trillion cubic metres in 2050; oil demand peaks at 105 million bpd in 2026 and declines to 65 million bpd in 2050. Key assumptions of this Mean Scenario include exponential growth of EVs, plastic recycling and bans on single plastic use reduce plastic demand; increasing recycling rates accelerate the decline of feedstock demand; a shift in both aviation and maritime fuels; robust growth in renewable power generation supported by declining costs will drive electrification of industrial and residential gas use which will intensify in the early 2030s with gas used to balance intermittent renewables; moderate development of hydrogen, batteries and carbon capture, utilization and storage (CCUS). In this scenario, gas is considered an important part of the transition towards a low-carbon world in markets that are currently highly dependent on coal.

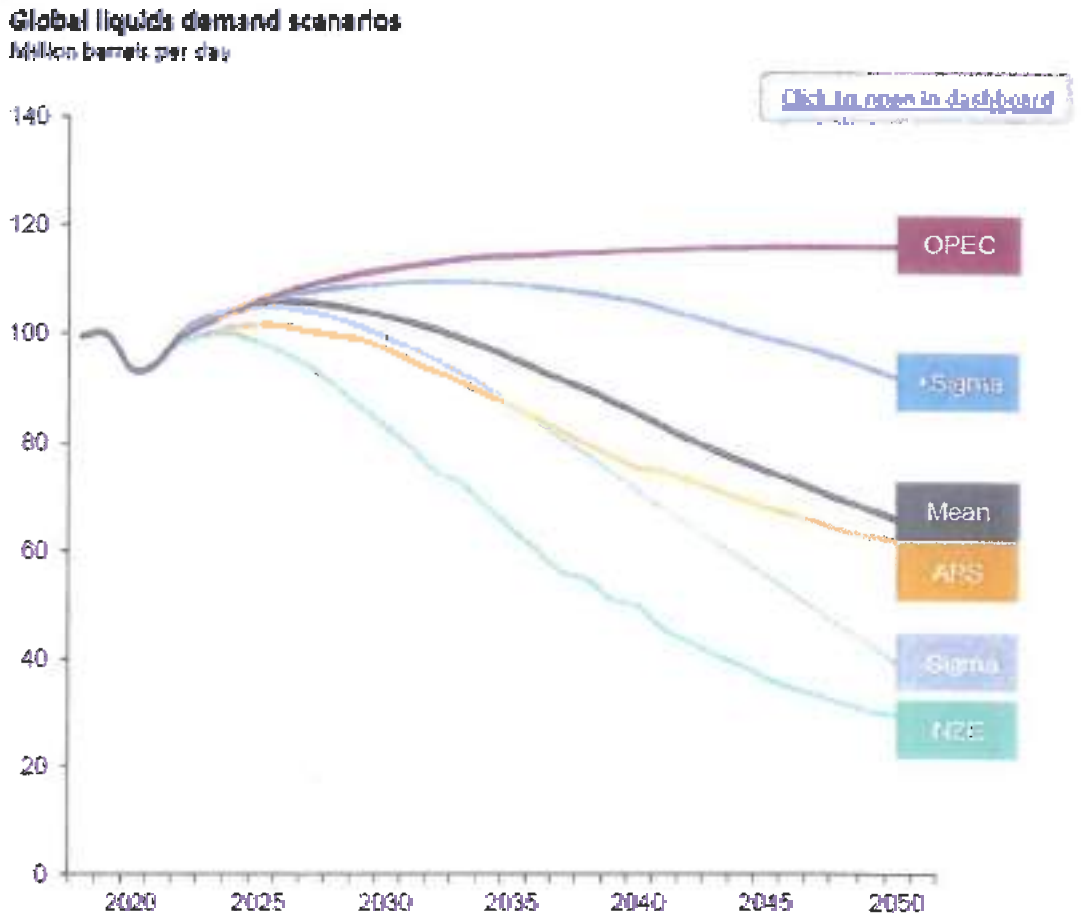
- **RystadEnergy +Sigma (2.2°C) scenario:** the 2.2°C scenario shows gas peaking in 2037 at 5.1 trillion cubic meters and declines to 4.4 trillion cubic meters in 2050; oil demand peaks in 2032 at 109.5 million bpd and declines to 92 million bpd in 2050. The +Sigma sees slow EV adoption, especially in non-OECD countries; low increase in plastic recycling rate; aviation jet displacement is limited, as is maritime gasoil; gas is considered an important part of the transition to a low-carbon world across major gas markets with continuous growth in demand for gas in Asia; gas demand in the power sector continues to grow, replacing coal in the power sector but peaking in 2030 due to slower growth in renewable power generation driven by lower investment in new capacity.

- **Stated Policies Scenario (STEPS) (2.4 °C):** This scenario is a reflection on what governments are actually doing to reach their targets and objectives across the energy economy and aspirational energy or climate targets are not automatically assumed to be met i.e. a proxy for industry business-as-usual (Prince, et al. 2023). IEA's Stated Policies Scenario (STEPS) describes a world where no new climate policies are implemented, beyond those that are already in force. Prior to 2022, STEPS projected rising oil demand until at least 2040 and gas demand until at least 2050, but the 2023 edition projects that coal, oil and gas will all peak before 2030. (Prince, et al. 2023). We refer to this scenario as a **slow transition** (Prince, et al. 2023).

- **OPEC Scenario:** The OPEC scenario sees a bullish liquids demand with gradual increase in demand up until 2045. Global oil demand is expected to rise from 99 million bpd in 2022 to 116 million bpd in 2045. This scenario assumes that the aviation, road transportation, and petrochemical sectors will each see oil demand grow with the largest demand increase from the road transportation sector as internal combustion engine (ICE) vehicles will continue to dominate the global fleet and account for more than 72% in 2045. With respect to refined products, major long-term demand growth is expected for jet/kerosene followed by ethane/liquified petroleum gas, diesel/gasoil, naphtha and gasoline. (RystadEnergy 2024).

Except for the OPEC scenario, these global energy scenarios illustrate the global decline in oil and gas use – most of the scenarios illustrate the peak in oil in the 2020s or early 2030s, and then gradually decline from there. The drivers responsible for these differences range from policy assumptions and the pace of technological advances to the cost competitiveness of oil substitutes and beyond. But it is clear that there is a transition away from fossil fuels, including oil and gas, although scenarios differ as to the pace and scale of the transition (International Energy Agency 2023, RystadEnergy 2024).

Figure 1: Forward Projections for Global Liquids Demand (RystandEnergy, 2024)



3. The Global Energy Transition to Net Zero is Reducing Demand in the Oil and Gas Sector

> ***It also reflects longer term trends: fossil fuel technologies have been losing market share to clean energy technologies across various sectors in recent years, and in many cases fossil fuel-powered technologies have already seen a peak in sales or additions.*** **(International Energy Agency 2023).**

For the first time in the decision text of a UN climate summit, known as a Conference of the Parties (COP), there was a call for "the phasedown of unabated coal power and phase-out of inefficient fossil fuel subsidies" at COP26 in Glasgow in 2016. This was followed by a strong push at COP27 in Sharm el-Sheikh in 2022, supported by 80 governments.

The Global energy scenarios largely indicate a global decline in oil and gas use (some from as early as the 2020s) although the pace and scale of the transition differ amongst

scenarios. For example, McKinsey's "current trajectory" energy transition scenario suggests that global oil demand could peak by 2027, while global gas demand could peak by 2040 (Leke, et al., 2022). The drivers responsible for these differences range from the implementation of stronger climate-friendly policies, improvements in technology, increasing energy efficiency and the cost competitiveness of oil substitutes amongst other factors (Dube, No date; International Energy Agency, 2023; RystadEnergy, 2024).

It is unlikely that the demand outlook will be linear and it is more realistic that in the short-term it is likely that oil and gas prices will remain somewhat volatile and rise and fall (Sanzillo 2024, International Energy Agency 2023). The IEA (2023) uses an example of how heatwaves and droughts could cause temporary jumps in coal demand by pushing up electricity use at a time when hydropower output may be constrained.

However, these changes in price are unlikely to reverse the more fundamental trend of new lower-cost (and lower-carbon) technologies as determinants of economic growth (Sanzillo 2024, International Energy Agency 2023). Notably, this declining demand is important for new oil and gas projects to take into account as the economic, financial and climate change risks of major new oil and gas projects must be taken into account (International Energy Agency 2023).

In addition to the energy scenarios, analysis of the global macroeconomic situation confirms the energy transition. Although developed economies saw an increase in natural gas demand in 2021 and the energy sector showed some financial recovery, this did not last long, and demand in 2022 was below pre-pandemic levels (Sanzillo 2024, International Energy Agency 2023). The Russian invasion of Ukraine in February 2022 resulted in fossil fuel companies earning record amounts due to inflation, fears of oil and gas shortages and higher interest rates (RAN; BankTrack; IEN; OCI; Reclaim Finance; the Sierra Club; Urgewald, 2023). As mentioned above, this did not last long, especially as Europe had an unseasonably warm winter, lowering their demand for oil and gas.

Thus, it is widely agreed that the global energy sector has been in a state of economic decline and this trend will continue (Sanzillo, 2024). Sanzillo (2024) substantiates this statement by noting that:

- The energy sector only has 3.9% of the stock market – declining from 28% of the stock market in the 1980s.
- During the decade before the Ukraine invasion, the energy sector lagged the stock market and for five years it placed last in the stock market.

- At the start of this century, coal was the leading source of electricity, commanding 50% of the electricity market. In 2023, it failed to command 20% in any given month.
- The oil and gas sector faces strong competition in most of its major end-product markets e.g. ExxonMobil CEO Darren Woods anticipates that there will be no new automobiles using gasoline by 2040 and the gas sector will likely decline.
- Plastics use is expected to grow, but recycling will put a damper on industry growth projections (Sanzillo 2024).

4. Key Drivers of the Energy Transition

Market signals, financial incentives and maturing technology have driven investment and deployment of clean energy (International Energy Agency 2023). Mass-manufactured technologies such as solar PV, wind turbines and EVs are leading the way. Sales of residential heat pumps and stationary battery storage are also rising fast (International Energy Agency 2023). Following the Russian Federation (hereinafter Russia) invasion of Ukraine, Europe has seen an accelerated move away from gas (International Energy Agency 2023). At the same time, implementation and updating of government policies and the slowdown of China's growth rate are expected to continue to drive the global energy transition.

Clean energy deployment is accelerating fast

In 2015, the market tipping was reached as renewable energy (RE) crossed average global grid parity, making it the cheapest from of new energy (PWC, 2020). Across the world, renewable energy generation is increasing as steady and continuing cost reductions take place - in 2019, 200 gigawatts (GW) of renewable power plants were built while only 100GW of fossil fuel and nuclear were constructed (Robertson, 2020; Jeliazkov, et al., 2020). Grid scale battery usage is increasing rapidly, and battery cost deflation is faster than wind or solar (Robertson, 2020).

IRENA (2018) notes that the share of renewable energy in the power sector will increase from 25% in 2017 to 85% by 2050, mostly through growth in solar and wind power generation. Investment in clean energy in sub-Saharan Africa increased USD 7.4 billion in 2018, from USD 2.3 billion in 2017 with the REIPPP attracting ZAR 209.4 billion (approx. USD 14.2 billion).

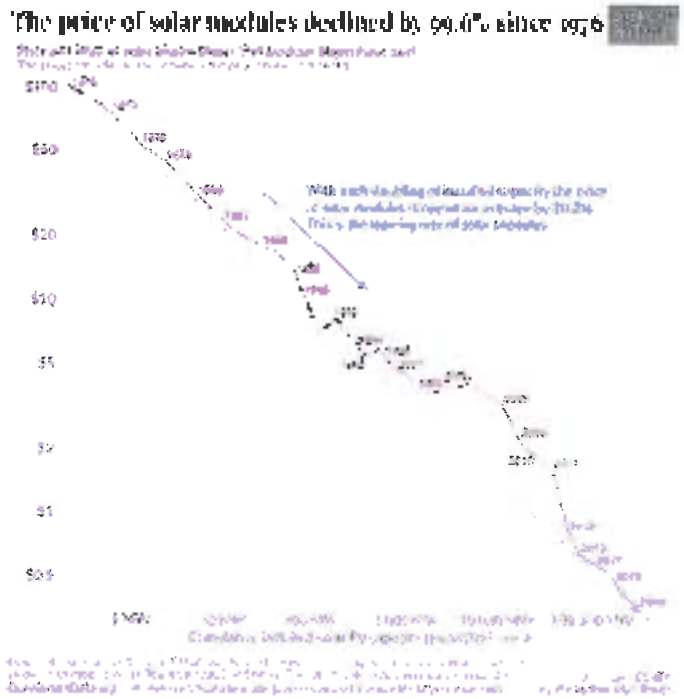
SystemIQ (2020) adds that green finance mechanisms are being developed to accelerate renewable energy deployment and to avoid the impact of stranded assets e.g., the European Commission's €1 trillion European Green Deal investment plan proposed in January 2021 which aims to assist all member states and will be used to support the

renewable energy-skilling of workers, helping SMEs to create new economic opportunities, and overall diversify economic activity, investing in the future of the most affected regions. Moreover, Multilateral Development Banks (MBDs) and investors have shifted their priorities to both financing the transition, and scaling up renewable energy, positing fossil fuel projects as high-risk investment prospect for future finance (SystemIQ, 2020).

As the costs of key clean energy technologies – solar PV, wind, heat pumps and batteries – fell by close to 80% on a deployment weighted average basis between 2010 and 2022, their uptake has increased (International Energy Agency 2023). The falling costs of wind and solar are due to the learning curves of clean energy and it's likely that the price difference between fossil fuels and renewables will become larger in future- with renewables likely to become even cheaper (Roser 2020). The result has been that electricity has expanded to become the basis of the entire energy system (Prince, et al. 2023). 'Importantly, these cost reductions cannot be reversed: the new technologies and means of industrial production cannot be "unlearned".' (Prince, et al. 2023).

As a consequence of increased electrification and deployment of wind, solar and battery technology, the economics of gas power plants have been threatened, making electrification rather than gas a more economical energy source. According to BNEF (2020), two-thirds of the world's population live in a country where either onshore wind or solar photovoltaic provide the cheapest source of new, utility-scale generation. Battery storage is now the cheapest new-build technology for peaking purposes (up to two-hours of discharge duration) in gas-importing regions, like Europe, China or Japan (BloombergNEF 2020).

The IEA (2023) documents the boom in solar manufacturing which has increased ten-fold globally over the last decade. They believe this trend will continue, with investments in the pipeline set to raise global solar module manufacturing capacity from about 640 GW in 2022 to over 1 200 GW in the medium term. The rapid expension of solar manufacturing suggests that the uptake in solar installations will continue.



Increasing energy efficiency

Although increasing energy efficiency hadn't been prioritised in the energy transition this trend is set to change: The IEA (2023) documents in their annual Energy Efficiency Report of 2023, that countries have mobilised $700 billion for energy efficiency projects since 2020. At COP28, nearly 200 countries pledged to double the global average annual rate of energy efficiency improvements by 2030 (from about 2% in 2023 to over 4% in 2030). The IEA (2023) adds that energy efficiency is currently seeing a strong global focus among policy makers as many governments are introducing new or strengthening existing policies and energy saving programmes. These countries include India which has enacted new policies for various sectors and the USA through their Inflation Reduction Act which has stimulated energy efficiency measures coupled with substantial job creation with over 2 million Americans working in energy efficiency, according to the National Resources Defence Council.

Buildings within cities and urban areas tend to represent the biggest sources of GHG emissions, contributing, on average, 60 percent of global emissions. According to C40 Cities (2020), building retrofitting could provide up to 55 percent of the GHG reductions needed to meet global 2030 targets and align the world with the 1.5 degrees Celsius trajectory. As a result, countries like South Africa, who have set targets for carbon reductions in alignment with the Paris Agreement, have identified the retrofitting of buildings as a key element in their climate action initiatives (C40 Cities, 2021; C40 Cities, 2020).

However, the outcomes from increased energy efficiency won't be immediate and energy efficiency gains are likely only to be realised over a period of years (International

Energy Agency 2023). The World Economic Forum estimates energy demand could be decreased by 31% across all sectors if businesses take action to reduce demand by 2030. The IEA (2023) calculates that energy efficiency pledges could cut energy costs in advanced countries by one-third, reducing CO2 reductions by 50% in 2030. Priorities vary by country, but key improvements at the global level come from upgrading the technical efficiency of equipment such as electric motors and air conditioners, from efficiency gains brought about by electrification and the switch away from solid biomass use in low-income countries, and from using energy and materials more efficiently. Further electrification of end-uses is a priority. EVs and heat pumps are central to this (International Energy Agency 2023).

The other benefits of increasing energy efficiency include increasing energy security, reducing air pollution and needing less clean energy to be installed, reducing costs. At the same time, increasing energy efficiency has the ability to create a substantial number of jobs. For South Africa, C40 Cities has calculated building interventions are poised to become a catalyst for job creation by 2030 in South Africa. C40 Cities (2022) highlights that building retrofits have the potential to create and sustain between 342,000 and 560, 000 jobs. This accounts for over 78 percent of the potential job opportunities stemming from the implementation of climate mitigation actions. Building retrofitting also offers the opportunity to create green jobs for vulnerable groups, such as women, youth and the unemployed (C40 Cities, 2022).

As the PWC (2020) report notes: there is no turning back the global energy transition and this market disruption is taking place against increasingly fragile African economies who depend on fossil fuels for foreign revenue. The market shift has impacted oil and gas companies as seen in their announcements of large losses, divestments, downscaling and lay-offs in an attempt to remain profitable (PWC, 2020). **Companies such as BP, Chevron, Shell, Total and Eni have also written off assets** based on the assumed oil price – with an estimated US$87bn reserves that are now assumed uneconomical (PWC, 2020). Another clear indication is that **the accountants and auditors of the big energy firms are beginning to acknowledging the transition** as Total, Repsol, Shell and BP now base their financial statements on price assumptions that are more conservative than their peers (Grant, 2020). BP's auditors, Deloitte, explicitly noted in 2019 that its previous impairment prices were not consistent with the Paris goals, based on a comparison to third party scenarios and BP subsequently amended its assumptions in Q2 2020 (Grant, 2020).

Technology is making it possible to decarbonise heavy industries

The Making Mission Possible Report by the Energy Transitions Commission notes that **it is technically possible to decarbonise heavy industries** (Energy Transitions Commission, 2020). Although many high heat applications for gas can be substituted

with cheap renewable power, there may be some applications for the foreseeable future that will continue to require gas (Robertson, 2020). Due to innovation, many technologies and business solutions are close to being brought to market that will make it possible to decarbonise heavy industries (Energy Transitions Commission, 2020). Similarly, Robertson (2020) predicts that by 2030, green hydrogen will be cost competitive across all 'hard to decarbonise' sectors. IRENA (2020) differs as it believes that the solutions may not be commercially mature or ready for wide adoption quite yet, especially as uncertainties remain about their potential and optimum use, and none will be easy to scale-up.

Rapid increase in Electric Vehicle Sales

Global oil demand is largely due to road transport (45% of demand) and petrochemicals (15% of demand). However, as internal combustion engines (ICE) are phased out and the uptake of electric vehicles increases, road transport will no longer be a source of oil demand growth. This change is expected to take place as soon as 2030, with projections assuming that the sale of ICE vehicles has already peaked (International Energy Agency 2023).

Government commitments and carbon neutral policies are rapidly moving to decarbonise the energy sector

Pressure on governments from civil society, peers and their own increasing concerns about the impacts of climate change have resulted in stronger commitments and policies to drive decarbonisation (International Energy Agency 2023). Globally, developed economies are beginning the shift away from fossil fuels by accelerating green policies and investments as 'carbon neutral' and 'net zero' have become real targets, embedded in national policies and legislation in order to align with the goal of the Paris Agreement (PWC, 2020; Robertson, 2020; Huxham, et al., 2020; IRENA, 2020). Unlike demand shocks like COVID-19 where prices and consumption may recover, the low carbon transition will bring long-term structural changes, influencing the value of physical and financial assets, tax flows, jobs and knowhow. These risks are known as "climate transition risks" (Huxham, et al., 2020).

Europe has increased its ambition to cut gas dependence due to its historic reliance on Russian gas. These commitments include:
Governments have also formed voluntary alliances on fossil fuel phaseout (International Energy Agency 2023). For example:

- Beyond Oil and Gas Alliance (2021) in which core members commit to ending new oil and gas licensing

- Clean Energy Transition Partnership, in which governments and financial institutions agree not to provide international public finance for fossil fuels.

- Targets for net zero emissions have now been set by governments (33 countries and the European Union plus businesses). As of June 2023, net zero emissions pledges cover more than 88% of global energy-related emissions and nearly 92% of global GDP (Net Zero Tracker 2023). 149 countries have pledged to meet a net zero emissions target (Net Zero Tracker 2023).

Bank Fossil Fuel Policies

Article 2.1c of the Paris Agreements aims to make "finance flows consistent with a pathway towards low greenhouse gas emissions and climate-resilient development." (Just Share 2023). The implication of this is that capital needs to be directed towards low-carbon solutions, and away from high-carbon activities (Just Share 2023). Thus, financial institutions, like banks, can support the goals of the Paris Agreement through their lending, investment and underwriting activities. The United Nations–convened Net Zero Banking Alliance (NZBA) and the sector-specific alliance for banks under the Glasgow Financial Alliance for Net Zero (GFANZ) are two alliances that have been formed within the banking sector to align to Article 2.1C (Just Share 2023).

Globally, despite over 125 banks embracing net zero commitments or joining NZBA since 2021, many of the banks have targets that are too low to meet the Paris Agreement or are heavily reliant on false solutions such as carbon offsets and discredited technologies such as Carbon Capture and Storage (CCS) (RAN; BankTrack; IEN; OCI; Reclaim Finance; the Sierra Club; Urgewald 2023). Many banks have policies that expose them to climate risk. However, the Banking on Climate Chaos (2023) report notes that there are some banks that are adopting restrictions on financing hydrocarbons. Examples include French banks Crédit Mutuel (coal policy) and La Banque Postale (strong fossil fuel policy); Danish Danske Bank (new policy excluding companies with upstream expansion plans) and HSBC starting to move towards exclusion policies.

South Africa's five largest banks (Absa Group Limited (Absa), FirstRand Limited (FirstRand), Investec Limited (Investec), Nedbank Group Limited (Nedbank), and Standard Bank Group Limited (Standard Bank) were analysed for their climate-related disclosures, policies and the extent to which their lending and investment activities support their stated commitment to the goals of the Paris Agreement (Just Share 2023). The research found that Investec has signed onto the NZBA; Absa, FirstRand, Investec and Standard Bank are signatories to the PRB while Nedbank is "in support of the Principles for Responsible Banking,". All these banks continue to finance the fossil fuel industry – and during 2022, many of these banks increased their exposure to fossil fuels. However, Investec's fossil fuel financing and exposure decreased, due to a large and unexplained reduction in the bank's oil exposure (Just Share 2023). All five of the SA

banks analysed made progress in their recognition of climate risks and commitment to global climate goals and have committed to reduce their financed emissions to net zero by 2050.

What is interesting is that although neither international nor South African banks are moving as fast as we need to align to the Paris Agreement, there have been some shifts and new policies excluding or limiting fossil fuels investments and exposure to climate change. Moreover, it is likely that SA banks will begin to implement stronger policies as the South African Reserve Bank has issued Guidance notes to both the SA banking and insurance sector in May 2024 (South African Reserve Bank 2024). These guidance notes set out the requirements for banks operating in SA to disclose their climate related risks and to put measures in place to reduce their risks. Amongst other things, the guidance notes also require banks to disclose their Scope 1, 2, and 3 greenhouse gas (GHG) emissions as well as:

- Climate-related transition risks: The amount and percentage of assets or business activities vulnerable to climate-related transition risks through exposure to transition sensitive sectors.
- Climate-related transition risks: The financed emissions of exposures to transition sensitive sectors.
- Climate-related physical risks: The amount and percentage of assets or business activities exposed to physical risks in geographical regions or locations.
- Capital deployment: The amount of capital expenditure, financing and/or investments deployed towards climate-related risks and opportunities (South African Reserve Bank 2024).

A slowdown in China's growth rate

China's growth has shaped energy markets and the global environment, accounting for more than 50% of global energy demand growth and 65% of the rise in energy sector CO_2 emissions over the last 10 years as China experienced rapid electrification. At the same time, China is massively increasing its domestic petrochemical production: petrochemical production is responsible for around 80% of growth in oil product demand in China over the 2019 to 2023 period.

However, China's growth rates have slowed and there is an expectation that its total energy demand will peak around the middle of this decade; with stable and then slowly declining demand, clean energy growth is sufficient to drive a decline in fossil fuel demand and hence emissions.

5. Transition Risk

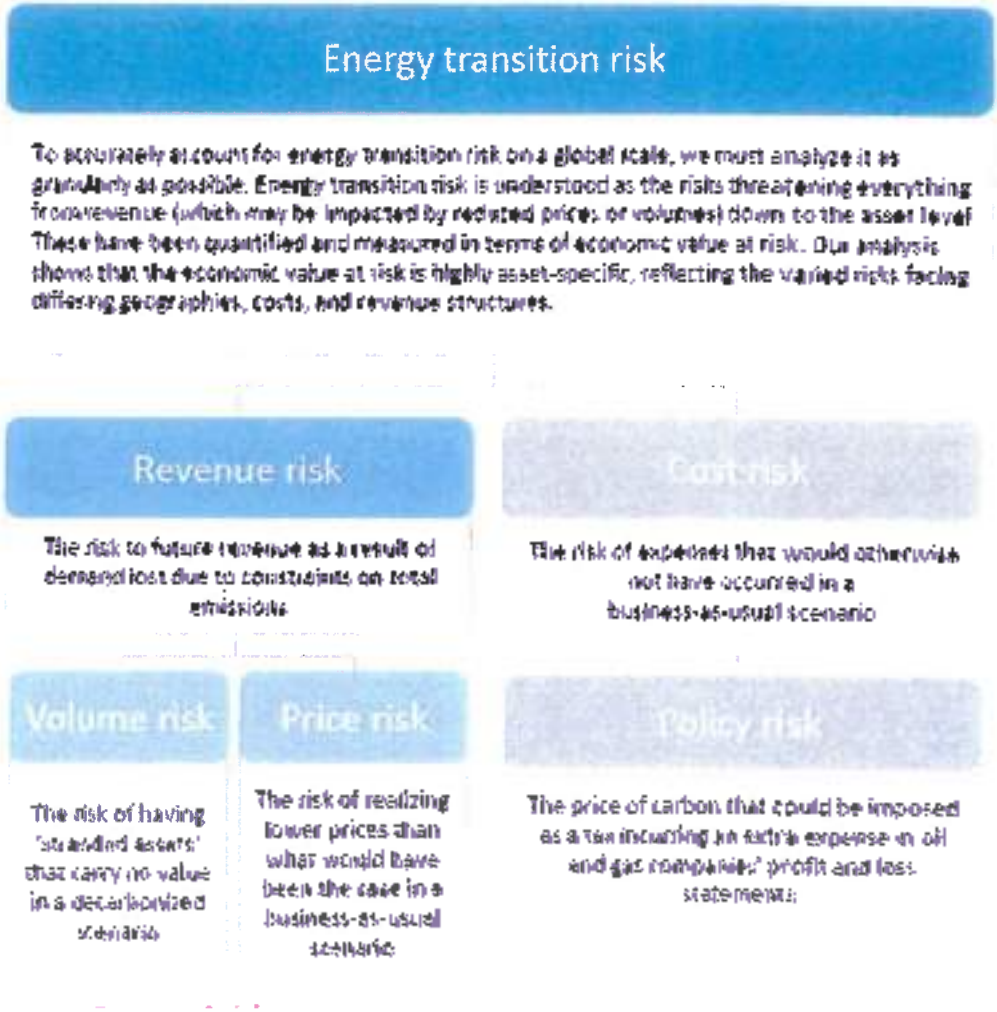
In the report titled, 'Understanding the impact of a low carbon transition on South Africa' Huxman et al (2019) describe transition risk as the risk that the value of assets and income are less than expected because of climate policy and market transformations, such as the transition away from fossil fuels. The African Climate Foundation (No Date) defines transition risks as liabilities that the banking and insurance industries would hedge against. They note that transition risks are increased in countries with poor governance. Carbon Tracker suggests that the O&G industry should practise prudent risk management by having a cautious view of the future, considering higher risk level and limiting capital expenditure to only competitive projects (Carbon Tracker, 2023).

RystadEnergy (2024) finds that the energy transition risk is comprised of both revenue risk and cost risk (RystadEnergy, 2024). Although these risks tend to be highly asset-specific, the economic impact on African countries regarding stranded assets and transition risks are analysed according to whether these countries are existing petrostates[1] (Nigeria and Algeria), emerging[2] gas producers (Mozambique, Tanzania, Mauritania and Senegal) and countries currently exploring for gas (South Africa and Namibia) (Carbon Tracker, 2023). Modelling indicates that both current and emerging African petrostates should be cautious when considering investing in gas and gas infrastructure because investments in African gas are ultimately value destructive (The African Climate Foundation, 2022).

[1] Petrostates are countries economically dependent on the extraction of oil and gas

[2] Emerging petrostates are those countries that have only recently discovered oil and gas and are wanting to exploit these discoveries (Prince, et al. 2023).

Figure 1: Energy Transition Risk



Petrostates

Most producers are ill-prepared for the coming peak. (Prince, et al. 2023)

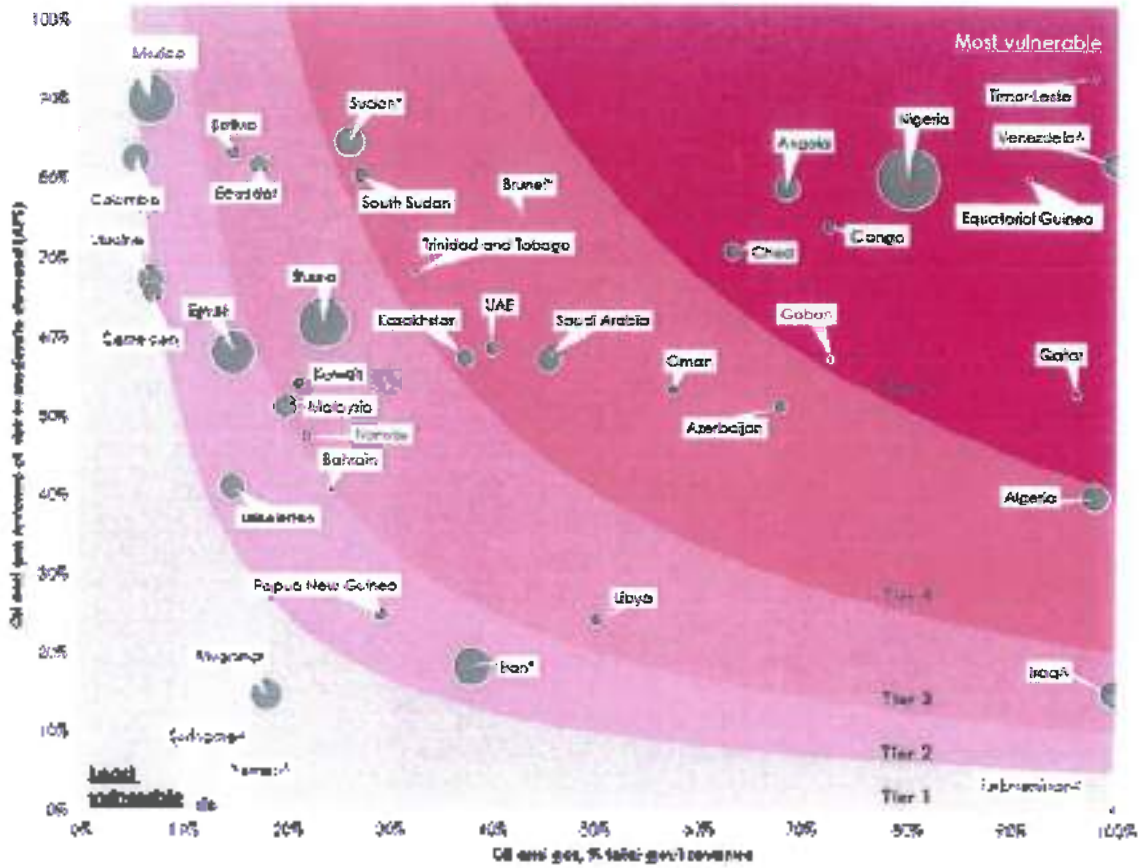
African oil- and gas-producing countries are facing difficult times: they are vulnerable to the global energy transition because it is likely that reduction in the demand for oil and gas, due to the energy transition, will lead to a fall in commodity prices for oil and gas, reducing production volumes and subsequent revenue reductions as their exports decline (Prince, et al. 2023). African countries exhibit a high potential revenue loss, and represent countries with high oil and gas revenue dependence i.e. the percentage of O&G revenue as a percentage of total government revenue tends to be high (Prince, et al. 2023). Moreover, high population growth in African petrostates compound their vulnerability. The most vulnerable African countries are Equatorial Guinea, Nigeria, Gabon, Congo, Angola and Chad (in that order).

At the same time, **additional investments in O&G are highly likely to be stranded assets** (Boyer 2021, Prince, et al. 2023, Dube No date, RystadEnergy 2024). According to McKinsey, replacement of approximately 60 percent of Africa's current oil production could become uncompetitive by 2040, facing the increased risk of stranded assets (Leke, Gaius-Obaseki and Onyekwelli 2022). In Nigeria, petroleum exports make up more than 85 percent of the government's total export revenues (Leke, Gaius-Obaseki and Onyekwelli 2022). African petrostates face extensive risk and projections have questioned the potential revenue in light of the accelerating energy transition:

- More than 2/3 of the Mozambican NOC Empresa Nacional de Hidrocarbonetos' planned investment would end up in projects that would not break even.
- Almost ½ of the Nigeria National Petroleum Corporation's projects would not break even either, putting at risk $13 billion
- Almost ⅓ of the Republic of Congo SNPC's planned expenditures would not yield any profit (between $500 and $600 million)
- Senegal's oil and gas resources might already be stranded, e.g. the Sangomar field original internal rate of return was estimated at 28% but drops to 9% when taking into account the energy transition and operational delays.
- Ghana would see less than half of their projected revenues materialise in net zero by 2050 scenario,
- The nascent oil and gas projects in Uganda would yield no revenues (Boyer 2021).

Oil and gas often make up a high proportion of government revenues, thus if oil prices fall, these **governments will struggle to balance their budgets as they need to continue providing public services for their populations**. Boyer (2021) suggests that governments should be transparent about project costs and contractual terms to allow a proper understanding of each project's economics and viability under different parameters.

Figure 3: **Vulnerability of Petrostates' Total Government Revenues to Reduced Oil and Gas Demand Resulting From A Moderate-Paced Energy Transition**



Source: Rystad Energy, IMF, CTI Analysis

Notes: Bubble size indicates relative population size. ' indicates countries where we have not been able to update oil and gas as % of total govt revenue data since our last analysis. ^ indicates either greater oil and gas revenue than total government revenue (Iraq, Venezuela) or improved oil and gas revenues in our moderate transition, due to unknown gas pricing and demand

The fiscal breakeven price or price necessary for an oil-exporting state to balance its budget is another way to measure a state's vulnerability or economic resilience. Although O&G producers do not know what demand and price will do in the future, it is likely that an early excess of supply is likely to push down prices, leading to low subsequent investments, and resulting in higher prices in the short term. Essentially, the **lower the production price is for a state, the less vulnerable these states are** – it's important that a petrostates fiscal breakeven price is higher than the average price of Brent crude oil (approximately USD 80 per barrel in 2023) (Prince, et al. 2023). Therefore, **only those petrostates that have reduced costs and carbon intensity and become aggressively competitive will be viable** as overall demand and markets become more competitive during the energy transition. The Global Energy Scenarios forecasts that in

the Net Zero Emissions scenario oil will be around $15 per barrel and the Mean scenario forecast oil price at around $65 per barrel from 2027 to 2050. At this stage, few petrostates will have a breakeven fiscal price i.e. their costs are not profitable.

Emerging Petrostates

The global transition to Net Zero increases the financial risk for countries who are "emerging petrostates". Oil and gas producers will face a **declining demand plus lower commodity prices** on future revenues – and these aspects must be **factored into development of new oil and gas projects** as discoveries with less competitive breakeven price risk becoming stranded assets (RystadEnergy 2024., Prince, et al. 2023). At the same time, these **large capital investments** take years to develop the infrastructure required to extract oil plus **need decades of production to recoup costs** something that is highly unlikely to materialise, given the need for the energy transition (and noting that most O&G projects are only economically feasible if most of the products are exported).

Despite these concerns for emerging producers, African countries continue to trying to exploit their oil and gas finds. However, Prince et al. (2023) warn: '...they run the risk of wasting precious capital on upfront oil and gas investments, without realising the future cashflows they may be planning for.' i.e. **these 'assets' will likely be stranded before these countries are able to realise revenues.** Noticeably, faster and deeper energy transitions will affect demand more strongly and trigger higher risks of stranded assets. The analysis by ACF (no date) indicates that numerous LNG projects currently approaching or beyond their final investment decisions (FID) would no longer be economical.

Examples indicate that many countries may only begin exporting their oil and gas after fossil fuels are set to peak in the mid-2020s. Most African oil and gas projects take over 12 years to start producing and then these countries need to payback the investment costs (Payback periods for LNG projects can span 15 years, with contracts often accompanied by 20-year take-or-pay clauses.) before they begin to produce (The African Climate Foundation, no date).

This means **that if countries find gas in 2025, then they will likely only start producing in 2037** but will still **need to payback the investments costs**, at least until 2052 (depending on how big the find and how profitable the markets will be) – by which time they will need to close operations due to being obsolete, uncompetitive and not financially viable as well as due to climate change commitments. During this time, there will not be money flowing into the country i.e. no benefit for the country in question but there will be debt to repay. Added to this, analysis finds that African oil and gas assets are on average 15% to 20% more expensive to develop and operate and 70 to 80 percent

more carbon intensive than global oil and gas assets (Leke, Gaius-Obaseki and Onyekwelí 2022).

These examples include:

- **Uganda** which has faced delays on its oil and gas project e.g. the East Africa Crude Oil Pipeline which is likely to begin oil exports in 2025
- **Mozambique** has billion-dollar investments, on top of the increases in sovereign debt, which will require revenues to pay back well beyond peaking demand
- BP's floating LNG project along the border between **Mauritania and Senegal** has been delayed but is expected to be operational next year.
- The Mauritanian government is hoping to agree a business plan for a major offshore gas field in **Mauritania** in the coming years, with Shell also exploring for oil in the area.
- **Ghana** has been aiming to double its oil production and the government is selling more exploration rights in the hope of boosting production amid a severe economic crisis (Prince, et al. 2023).

Companies are at risk across the entire value chain

The road ahead will be unlike any the industry has travelled before. (RystadEnergy 2024).

RystadEnergy (2024) note that along the full value chain i.e. exploration, development and production, companies in the oil and gas sector are at risk as we transition global energy systems. Included in their stakeholders are investors and banks (likely consultants too) who have traditionally earned an income from the oil and gas sector.

While the whole oil and gas sector will be negatively impacted, some companies might be better positioned to remain competitive for a longer period of time. At this stage, it is estimated that national oil companies (NOCs) hold the most competitive reserves (i.e. produce at lower costs), so they will probably remain more competitive in a low-price oil market environment – although they will face a minimum of a 20% decline in liquid production rates by 2040 (Prince, et al. 2023). Therefore, towards 2050, most NOCs will hold an increasing share of global production and investments in all scenarios. However, these outcomes aren't certain for all NOCs and some NOCs are less competitive than others (Prince, et al. 2023). At the same time, NOCs have fewer incentives to change as governments want to maintain income from petroleum. Public companies are more likely to be spurred by persistent shareholder or external pressure to embrace lower-

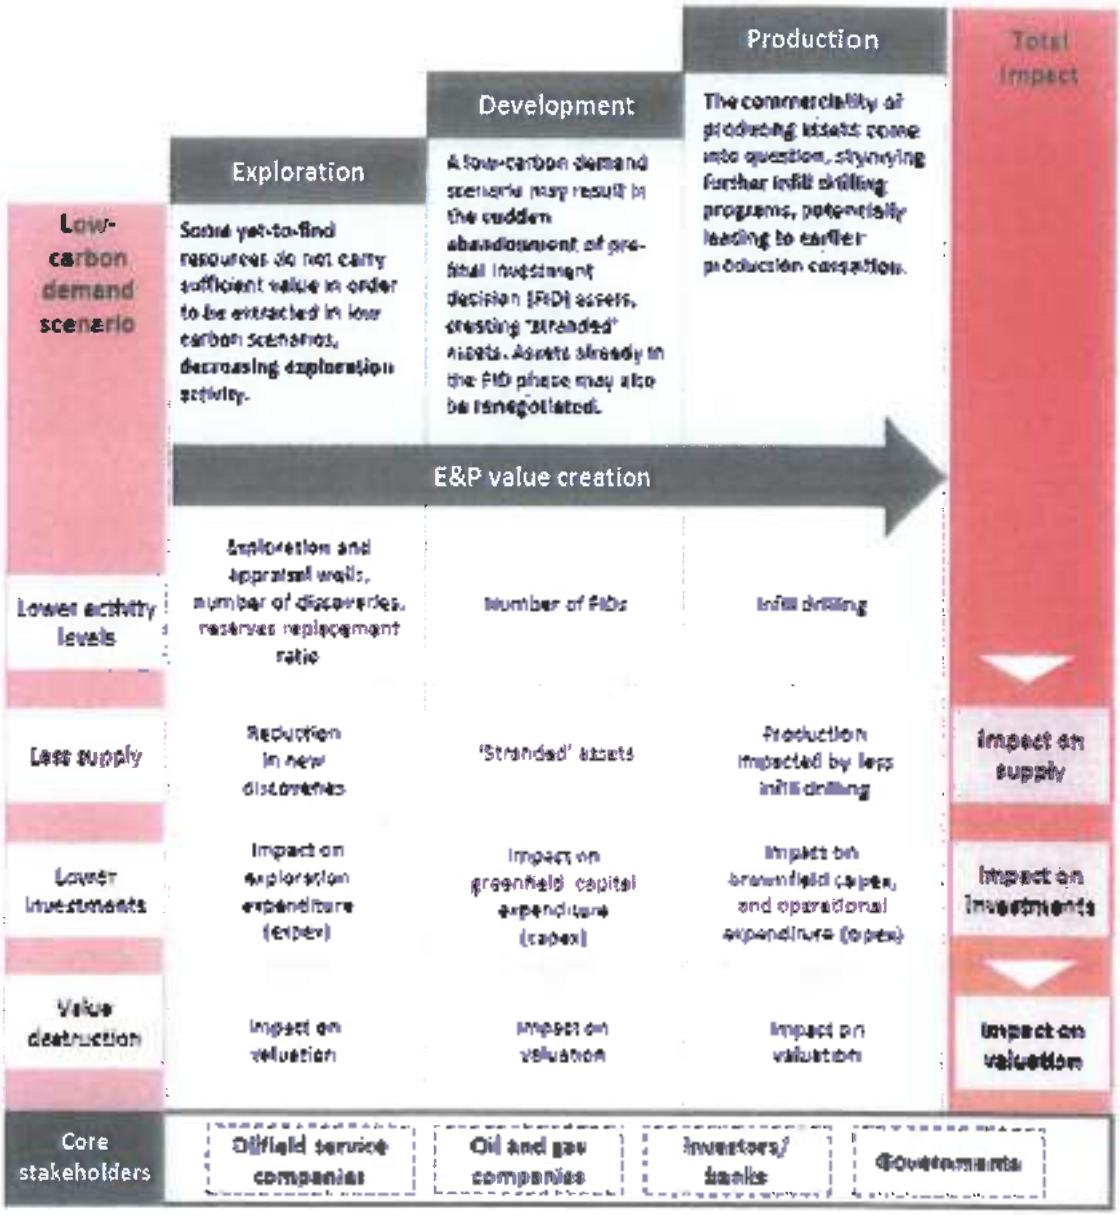
carbon operations (RystadEnergy 2024). Non-NOCs will likely face over 50% decline in demand (Prince, et al. 2023).

Oil and gas companies are in denial about climate change and analysis of eight of the largest integrated oil and gas companies — BP, Chevron, Eni, Equinor, ExxonMobil, Repsol, Shell, and TotalEnergies (the "oil majors") indicate that none of their plans or strategies are aligned to the Paris Agreement (RAN; BankTrack; IEN; OCI; Reclaim Finance; the Sierra Club; Urgewald 2023). Despite signing onto pledges, major oil and gas companies have been backsliding and it is unlikely that any of these companies will willingly make the energy transition (RAN; BankTrack; IEN; OCI; Reclaim Finance; the Sierra Club; Urgewald 2023).

Prince, et al. (2023) suggest that the oil and gas sector is trying to slow down the process of transition by trying to innovate technology that is currently dependent on oil and gas. They use the term the 'sailing ship effect'[3] to describe this inefficient use of capital to delay an inevitable transition – that would have been better spent on new technologies and innovation (Prince, et al. 2023). The example cited is Saudi Aramco's doubling of its spending on research and development in the last five years, with a particular focus on the efficiency of internal combustion engines.

[3] The "sailing ship effect" describes the increase in sailing ship innovation in the mid-nineteenth century to delay their replacement with steamships (Prince, et al. 2023).

Figure 5: Companies are at risk along the whole value-chain



Transition Risk and South Africa

South Africa would be considered an emerging petrostate, thus, if SA plans on exporting O&G, it is likely that due to the global transition to net zero, SA gas will not be sufficiently price competitive to be exported and the global demand is likely to decline by the mid-2020s i.e. there will be no market for SA O&G (IEA, 2024; International Energy Agency, 2023). If the intention is to use the O&G domestically, then models developed in SA indicate that South Africa's power needs can be met with very little gas and the large majority of new energy new generation capacity should be wind and solar, with an increasing requirement for flexible (dispatchable) capacity to support this (Roff, et al. 2022). Moreover, gas power is almost triple the cost of renewable energy and thus not

cost-competitive (Roff, et al. 2022). Research by NBI indicates that either way SA will have to substitute gas with greener alternatives and phased out by 2050 for South Africa to achieve a net-zero 2050 target (NBI, BCG, BUSA, 2022). This indicates a high probability of stranded assets if SA invests in both the upstream and downstream O&G sector.

In 2019, Huxham, et al analysed South Africa's transition risk. They found that **South Africa faces transition risk of more than $120 billion in present value terms between 2013 and 2035.** The authors note that South Africa's trade-offs associated with a low-carbon transition are particularly acute because of the high levels of unemployment and inequality, together with a strong reliance on fossil fuels. **This analysis did not include analysing the risk from the offshore oil and gas industries** but they did make key recommendations for the South African government and businesses prior to investing in these projects. Moreover, they note that if the government took action to mitigate the risks, it could avoid potential economy-damaging risk concentrations and in so doing, reduce the costs associated with the decarbonisation of the South African economy:

> 'The analysis ... demonstrates that the risk to South Africa – its companies, workers and public finances – of **continuing with business as usual is higher than the costs of managing those risks through proactive management of risks to the economy**.' (Huxham, et al., 2019).

A key recommendation was that **South Africa should avoid or delay new investments that could add to South African climate transition risk** until the market for the related product is certain. South Africa needs to understand thoroughly the consequences and likelihood of the transition and related risks as well as determining whether these investments continue to make sense within South African's development ambitions. Thus, South Africa should introduce climate transition risk assessments as a standard condition of application for public sector procurements, financial assistance such as guarantees to finance on preferential terms from state-owned financial institutions or other fiscal incentives, could help avoid investments where the risks outweigh potential or likely benefits (Huxham, et al., 2019).

Making the risk and its eventual allocation explicit may also reduce the incentive for local entrepreneurs to compete to buy emissions-intensive assets from international mining majors, leaving more transition risk with investment grade balance sheets who are strong enough to absorb it. Such a step would also make it easier for government to budget for the effect on the public finances. (Huxham, et al., 2019).

The long-term structural changes in demand for fossil fuels, will have enormous repercussions as they will influence the value of physical and financial assets, tax flows, jobs and knowhow (Huxham, et al., 2020).

6. The Danger of Stranded assets

Stranded assets are assets that become devalued or fail to generate an economic return before the end of their economic lifetime or can no longer be monetised due to changes in circumstances (Dube, No date; Carbon Tracker, 2023). The International Energy Agency defines stranded assets as "those investments which have already been made but which, at some time prior to the end of their economic life, are no longer able to earn an economic return". Simply put, stranded assets are projects that fail to deliver adequate returns as conditions change (Grant & Coffin, 2020). These investments may involve the purchase of rights to explore in a given area, or assets with infrastructure in place actually producing hydrocarbons. Livsey (2020) notes that global investors are shifting their investments away from the traditional energy sector and this poses a big problem for energy groups whose fossil fuel reserves may never be extracted due to climate change. The energy groups will then be left with stranded assets, having to write off substantial amounts of their fossil fuel reserves – estimated to be over $900bn — or one-third to half the current value of big oil and gas companies (Livsey, 2020). Hurst (2020) highlights the impact that COVID-19 has had on companies which have abandoned projects that are no longer viable. Moreover, Livsey (2020) predicts that oil producers will be hit twice – fossil fuels will lose their value while simultaneously carbon taxes will reduce demand further.

Economic modelling shows that to achieve Net Zero Emissions in 2050 (NZE2050), with the current levels of investment in O&G, over US$350 billion in African oil and gas assets would be stranded, with more than US$90.3 billion in stranded assets in Nigeria alone (The African Climate Foundation no date). Global Energy Monitor (2022) documents a US$245 billion planned expansion of gas infrastructure that is underway in Africa- most of this gas is intended to support Europe's short-term energy crisis resulting from Russia's invasion of Ukraine. This will likely lead to stranded assets and a failure to invest as strongly as necessary in Africa's domestic generation capacities and renewable energy future (Global Energy Monitor, 2022).

At the end of January 2021, the risk of stranded assets facing energy companies was highlighted as rating agency S&P increased its risk rating for the entire oil and gas sector from "intermediate" to "moderately high" because due to the move away from fossil fuels, poor profitability and volatile prices (Butler, 2021). As such, 13 oil and gas companies were warned that they may be downgraded in weeks. The companies on notice of a possible downgrade are Australia's Woodside Petroleum as well as multinationals Chevron, Exxon Mobil, Imperial Oil, Royal Dutch Shell, Shell Energy North America, Canadian Natural Resources, ConocoPhillips and French group Total (Butler, 2021). S&P are also considering downgrading four large Chinese producers – China Petrochemical Corp, China Petroleum & Chemical Corp, China National Offshore Oil Corp and CNOOC (Butler, 2021).

'Embarking on a large-scale gas-to-power strategy given these realities creates significant economic and environmental risk.' (Roff, et al. 2022).

If there is no economic rationale for large-scale gas use in power and there is no international market for O&G, then following the SA government's outdated vision would deliver assets that are stranded (Roff, et al. 2022). Moreover, using the logic from emerging petrostates, if SA were to find Oil or Gas in 2024, it would likely take at least until 2034 to start producing – and then SA would have a payback period of approximately 15 years (i.e. until 2049) before SA would begin to see any profits on these investments. However, SA will then need to shut operations due to climate change commitments by 2050 (if the global market for O&G even exists at that stage, which from the energy scenarios, seems unlikely). During this time, SA is unlikely to see fiscal benefits such as increases in economic growth.

From a macroeconomic perspective if SA pursues an extractive O&G policy, it is likely that SA's levels of debt will increase and credit ratings are likely to drop further.

7. Lessons learnt from other African countries

South Africa should look to both African and global countries for lessons on the extraction of oil and gas reserves. In February 2024, Bloomberg documented some of the challenges facing African countries regarding their O&G finds, noting Senegal's economic woes:

> *Senegal joins other African countries that have struggled to ride some of the world's biggest oil and gas discoveries in decades. The finds have rarely lived up to their promise, often doing more harm than good. Everything from project delays to political uncertainties and mismanagement have capped export revenues, forcing the nations into additional borrowings and worsening their financial situations. Senegal's debt is becoming more expensive, Mozambique has had to restructure its loans and Ghana defaulted amid the mismanagement of its oil and gas production.*
>
> *The discoveries have also done little to improve the energy situation at home. Domestic markets across the continent are no match for the lucrative ones beyond its borders. Foreign companies balk at developments that don't target export markets, leaving local economies with limited access to their own gas that can be used to generate electricity for homes and industry. Almost 600 million people, or just under half of Africa's population, lack direct access to energy even as 6% of the world's gas and about 7% of its oil is produced there.*

Mihalyi & Scurfield (2020) highlighted the benefit of hindsight as they analysed 12 Sub-Saharan African countries who had found oil and gas deposits during the period 2001 – June 2020. Their findings were that all 12 countries fell short of forecasted expectations.

The economic outlook of these countries has changed following these disappointments, especially following the slump in commodity prices that began in late 2014 (Mihalyi & Scurfield, 2020).

1. Overvaluing non-renewable resources

For oil and gas to be commercially viable, the deposit size of the find is important. Mihalyi & Scurfield (2020) find that the commercial viability of resources varies significantly and may change over time. Moreover, many of the African countries they analysed suffered disappointment after their initial discoveries. One reason that discoveries were overestimated was due to companies wanting to emphasize positive results to inflate their share prices. This also has the effect of misleading governments and other companies exploring in the same areas (Mihalyi & Scurfield, 2020). The PWC's Africa Oil and Gas Review (2020) estimates that the demand slump in global oil will result in lower prices per barrel over at least the next 20 years which will 'cost' Africa R14,55tn in lost export revenues.

In 2020, Huxham, et al analysed how a global low carbon transitions could affect the profitability and value of Uganda's two principal under-development upstream oil fields; the export pipeline from the Kabaale industrial park near Hoima to Tanga port in Tanzania, and the East Africa Crude Oil Pipeline or EACOP (including the planned oil refinery to be built in the Kabaale industrial park). Huxham, et al (2020) note that in Uganda, the value of the upstream oil reserves has fallen by more than 70% (from R887 billion to R262 billion) since 2013. They argue that if a global low carbon transition consistent with keeping global warming to well below two degrees occurs, the value of Uganda's oil reserves could fall a further R145 billion (or 56% of its value in 2020) and would be worth 88% less than they were in 2013.

2. Timeline from discovery to production

Industry studies indicate that oil and gas projects frequently have time and cost overruns, and more so in Africa (Mihalyi & Scurfield, 2020). Globally, the average amount of time it takes to get from discovery to production is 7.5 years. In Sub-Saharan Africa, the average time is around 12 years. For gas assets, the average time is nine years globally, versus 15 years in Africa (Mihalyi & Scurfield, 2020). The extensive time and cost overruns may make these extractive projects less commercially viable, especially within the context of falling demand.

3. Government revenues generated

African government revenues have fallen significantly short of forecasts. The most recent revenue projection is on average 63% lower than was initially estimated (Mihalyi & Scurfield, 2020). The shortfall has been attributed to; lower rates of production than

originally forecast; challenges associated with taxing production as the resource sector

Mozambique government revenues lower than projected

There is no shortage of natural gas in Mozambique, however, the challenge lies in mobilising investments needed to bring the gas to market (Hubert, 2019). The first project to extract gas in Mozambique is the Coral South Floating project, led by Eni. The first exports are expected in late 2022.

Previous revenue projections generated by the International Monetary Fund (IMF), the World Bank-funded Gas Master Plan, and Standard Bank analysis, suggested very substantial government revenues from LNG by the early- to mid-2020s. These forecasts assumed early first exports, the rapid expansion of production capacity, and very high LNG prices (Mihalyi & Scurfield, 2020).

The predictions for government revenues from FLNG are crucial for Mozambique given the challenges of external debt and declining donor support (Hubert, 2019). Three different government revenue forecasts have been generated: Eni has indicated that the government can expect to generate around $16 billion in revenue over the life of the Coral South FLNG project; the Mozambique Ministry of Finance model suggests the project could generate around $11.5 billion in revenue; while the Mozambique Minister of Mineral Resources and Energy reported that the project could generate up to $24.5 billion.

The IMF projections for Mozambique appear flawed as they estimated that corporate income tax would be paid in the first production year, which experts believe is unlikely (Mihalyi & Scurfield, 2020). Moreover, Hubert (2019) estimates that the construction of the liquid natural gas (LNG) facilities needed for export will cost tens of billions of dollars.

An alternative forecast by Hubert (2019), using an assumed oil price of $70 per barrel in 2022, forecasts government revenues of around $11.6 billion over the life of the project. However, government revenues are highly sensitive to oil prices and if the price increases to $85 per barrel they estimate government revenues of $19 billion, while at $55 per barrel revenues would fall to $5.5 billion. Hubert (2019) suggests that government share of revenues is low at approximately 49% and that timing is a challenge as the rear-loaded nature of the agreement means that government revenues are likely to be very modest in the early years of production, especially if there are cost over-runs, or if prices remain low. This means that the start of significant government revenues will be pushed back even further (Hubert, 2019).

can be hard to tax effectively; underestimates of costs or cost deduction; and, mistaken fiscal assumptions in modelling (Mihalyi & Scurfield, 2020). In addition, the share of after-cost revenues that flow to the government as opposed to companies (known as the 'government take') has not met with expectations (Hubert, 2019).

---

8. The Resource Curse and Local Maldevelopment

The failure of states to improve the social and economic conditions of their citizens despite being rich in resources such as oil and gas has been described as the 'Paradox of Plenty' or the 'resource curse'. The paradox is that, on average, countries with an abundance of non-renewable resources tend to have lower levels of economic

development and growth than those without such resources (Lagercrantz & Khabbaz, 2019; Onyeukwu, 2007; Stiglitz, 2012). In addition, countries rich in extractive resources tend to have higher levels of inequality and lower levels of democracy (Stiglitz, 2012; Lagercrantz & Khabbaz, 2019; Overy, 2019).

In general, countries with extensive oil and gas reserves do not develop their own economies by reinvesting their wealth. This is largely because weak political institutions and underdeveloped civil societies make it possible for political elites within mineral or non-renewable resource rich countries to redirect much of the income to themselves. This, often deliberate, mismanagement of resource revenues means that mineral resource rich countries tend to underinvest in education and other important public goods. This underinvestment is exacerbated by the neglect of taxes as a source of revenue because extractive revenues are so high.

In addition, resource rich countries fail to diversify their economies adequately, prioritising the quick gains that come from extraction, over more long-term economic planning. This often results in the agricultural sector being neglected, leading to increased poverty in rural populations. It also leads to underemployment as jobs are not created in other economic sectors. All of this is further compromised by the volatility in non-renewable resource prices which causes unstable revenue streams, a situation made worse by commodity trading (Stiglitz, 2012; Onyeukwu, 2007; Romanova, 2007).

It is unsurprising that this unstable and chaotic context gives rise to conflict between different political forces within countries over access to non-renewable resource rents. Gillies (2020) describes the emergence of the 'rentier state': A political system where elites allocate resource wealth to extend their power rather than to provide public goods (Stiglitz, 2012; Lagercrantz & Khabbaz, 2019; Gillies, 2020).

Seriously compounding the problem of the resource curse, is the phenomenon known as 'Dutch Disease'. Dutch disease, so named after the experience of the Netherlands after its discovery of North Sea gas and oil in the 1960s, describes problems that emerge with the rapid inflow of money that comes from non-renewable resource extraction. Firstly, it leads to currency appreciation, which results in a dramatic fall in the competitiveness of exports, be they manufactured or agricultural. This leads to falls in export revenue for these sectors, which are also battling against cheaper imports caused by currency appreciation. Both capital and labour to abandon these sectors in favour of the booming extractive sector, further damaging these sectors and boosting the extractive sector. This concentration of capital and labour can then become a problem within the extractive sector because it creates localised competition for goods like food (an industry which has already been undermined), and services such as housing. This then results in local costs rising for these types of critical goods and services, and results in economic recession (Lagercrantz & Khabbaz, 2019; Onyeukwu, 2007).

This localised influx of capital and labour can lead to serious social issues. Extensive migration into oil-producing areas places strain on public infrastructure and results in increased poverty rates, poor healthcare, high rates of child mortality, gender and economic inequality and crime. Research also shows how 'Dutch disease' both causes and contributes to the conflicts that occur in these countries (Onyeukwu, 2007; Romanova, 2007; Lagercrantz & Khabbaz, 2019).

Evidence shows that the economic, social, environmental and governance impacts that arise due to the extraction of oil and gas, tend to be localised in the regions where extraction takes (Lagercrantz & Khabbaz, 2019). The following sections explore in more detail the ways in which the paradox of plenty and Dutch Disease manifest themselves in non-renewable resource-rich countries. They look at problems that emerge both at national and local levels.

Moreover, research titled 'The forgotten resource curse: South Africa's poor experience with mineral extraction' finds that SA has experienced many of the symptoms outlined in the resource curse literature including relatively slow GDP growth, gross inequality, entrenched poverty and the creation of a rentier state. Overall, it finds that most of the SA population has failed to benefit from natural resource wealth – with sections of society actively harmed through the process of mineral extraction. This research classifies SA as a resource cursed state (Elbra, 2013).

It is clear from South Africa's macroeconomic outlook that many of the challenges outlined above still exist:

- South Africa's macroeconomic outcome is a bleak picture despite managing to avoid a technical recession in 2023 with real GDP growth at 0.6%. For 2024, South Africa's overall economic outlook is weakly positive with the National Treasury predicting GDP growth of 1.3% in 2024 and 1.6% in 2025 which is lower than the International Monetary Fund's forecast of 0.9% in 2024 and 1.3% in 2025. This low level of GDP growth has partially been attributed to constraints in the electricity and logistics sectors (especially rail and port infrastructure constraints) which needs structural economic reforms (Marais and Spangenberg 2024). To stimulate economic growth, there is a need for capital investment and specifically to invest in infrastructure and crowd in more private sector finance to support and implement projects.
- As of 2023, around 18.2 million people in South Africa are living in extreme poverty[4] and this number is forecast to increase in the coming years. Moreover,

[4] poverty threshold at US$1.90 dollars daily

SA has very high rates of child poverty. Although these levels have fallen as a result of a massive expansion of the Child Support Grant, given that the child population has grown over the past two decades, there were more children living in poverty in 2022 than there had been in 2003: 53% of children (11.1 million) were poor in 2022 and 38% (7.9 million children) were below the food poverty line, meaning that they were not getting enough nutrition.

- According to the most recent data, South Africa has the highest income inequality in the world, with a Gini coefficient of around 0.67. This is attributed to high levels of unemployment; very low wages or income for many of those that are employed; and high income and wealth levels for a small percentage of South Africans (the top 0.01% of people or 3,500 individuals own about 15% of all of the wealth).

- Unemployment levels in SA are estimated to be 32.6% (June 2023) but using the expanded definition of unemployment, it is more likely that over 44% of the working population is unemployed. The IMF predicts that unemployment will increase to 33.5% by the end of 2024 (using the narrow definition).

Local Economic and Social 'MaI/Development'

There is an assumption that the establishment of an oil and gas industry brings extensive local economic benefits to the areas in which the industry takes hold. But as we have seen, this has not been the general pattern in Africa, where regions rich in non-renewable resources have tended to be cursed, rather than blessed by them.

Recent research by the Ohio River Valley Institute analysed the 22 counties which make up the Appalachian methane gas region. While their findings revealed that these counties increased their contribution to US GDP by more than one-third between 2008 and 2019, during the same period measures of local economic prosperity—the economic impacts of that growth—not only failed to keep pace with the increased share of output, but actually declined (O'Leary, 2021) (O'Leary, 2021)

O'Leary (2021) documents this case of economic growth without increasing prosperity, or the resource curse. He notes that the gas wells produced substantially more gas than had been originally predicted which should have created over 200 000 additional jobs and increased tax revenues for these counties as well as other indicators of economic progress. Between 2008 and 2019 the number of jobs nationally increased by 10%, but in the Appalachian methane gas region, despite booming natural gas production, the 22 major gas-producing counties experienced a combined job growth of only 1.6% - with many of the counties experiencing substantial job declines during that time (O'Leary, 2021).

Moreover, the vast majority of Frackalachian counties experienced economic stagnation or outright decline and depopulation. O' Leary notes, '... there is little in the numbers to support the contention that the Appalachian natural gas boom has been or can be an engine for economic prosperity. If high production volumes were capable of creating jobs and prosperity, it would have happened. And there is a great deal which suggests that, in some cases, the industry may have the opposite effect.' (O'Leary, 2021).

Because of the jobs and other economic opportunities that sites of resource extraction appear to promise, local government institutions can become overwhelmed by the demand for social services and public goods. Evidence from the United States and Canada shows that the influx of people that follows the emergence of extractive industries results in increased demand for public services for several complex and often interrelated reasons. A growing population clearly demands increased infrastructural support in terms of basic municipal services such as health, education, emergency services, water and sanitation, electricity, and transport.

Health

Health services come under severe strain because of the negative health consequences of oil and gas extraction. Although the health effects of people exposed to upstream oil industry contaminants has been poorly studied, the health of communities living in close proximity to oil and gas extraction sites is affected by environmental impacts such as the contamination of air and water. Their health is also affected negatively through gas flaring and the long-term impact of climate change on these communities (O'Callaghan-Gordo, et al., 2016; CCAC Secretariat, 2020; Maduka & Tobin-West, 2017). Health outcomes range from chronic and recurrent respiratory diseases, abnormal haematological indices and increased susceptibility to blood dyscrasias, dermatological diseases and malignancies, nausea, dizziness, fatigue, genotoxity and alteration in hormonal status among others (Maduka & Tobin-West, 2017; O'Callaghan-Gordo, et al., 2016). Psychological disorders are also more prevalent in communities living close to oil and gas extraction sites (O'Callaghan-Gordo, et al., 2016). Moreover, persons living in gas-flaring host communities are 1.76 times more likely to be hypertensive than persons resident in communities outside of oil-rich areas (Maduka & Tobin-West, 2017). One resident living next to a flaring site in South Africa told the British *Guardian* newspaper in 2015, 'it's very scary: I feel choked up, I feel my lungs can't get air, I feel starved of oxygen. I get panic attacks' (CCAC Secretariat, 2020).

Research on human health and climate impacts of fracking in Appalachia found that premature deaths caused by the industry's pollution had an economic cost of R335 billion, while one year of life is lost for every three job years created by the industry. It also noted a disproportionate burden on the poor that included higher mortality risks induced by fracking-related air pollution. The lead author of this research stated, 'Private firms across the supply chain have not faced the full costs of natural gas development... and the public has effectively subsidized greenhouse gas and air pollution emissions that result in climate change and health impacts' (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Education

The demands placed on schooling systems also seems to outstrip the ability of local governments. Research shows that schools in resource-rich towns in the United States and Canada tend to have higher teacher turnover, lower attendance rates, poorer

academic results, and higher drop-out rates (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

At the exact point that demand for public services increases, the negative environmental consequences of the oil and gas industry can act to reduce local government revenues. This is because the oil and gas industry can reduce local taxes and income from other economic sectors such as tourism, forestry and fisheries. In addition, substantial local costs must sometimes be borne by local communities addressing issues such a s water pollution caused by the industry. (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Emergency Services

There is also increased demand for police and emergency workers because of the myriad of social ills that take place in resource extraction sites as documented by (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020). These social ills include:

- Increases in prostitution.
- Sex trafficking, including children, in oil boomtowns linked to 'a confluence of underlying forces including big oil money, an increase in drug cartels and drug use, degradation of women in a male-dominated workforce, increased access to weapons, and a rise in transient populations'.
- Increases in domestic violence, dating violence, sexual assault, and sexually transmitted diseases.
- Increases in traffic violations, traffic accidents and fatalities.
- Increased drug abuse and drug trafficking.

Evidence from the United States conclusively shows that crime levels increase compared to before the extraction of oil and gas and compared to other towns without extractive industries. 'With the arrival of drilling and fracking operations, communities have consistently experienced steep increases in rates of crime, variously including assault, rape, sex trafficking, larceny, and auto theft...Crime rates have increased even with additional allocation of funds for public safety' (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Local Businesses

Although an increase in people from a 'boom' in the oil and gas industry will create opportunities for some businesses, there are several sectors that will be impacted negatively by the oil and gas industry. In addition, volatile oil and gas prices are likely to impact negatively on local businesses as volatility increases business risks (O'Leary, 2021). The Ohio River Valley Institute notes that it cannot be assumed that companies will purchase from local suppliers, as many oil and gas companies already have

preferential suppliers from outside regions, and thus there is often little beneficial impact on local economies (O'Leary, 2021).

Other business can be severely negatively impacted. Findings from the United States and Canada demonstrate that the fishing industry, both commercial and small-scale, tourism, and tourism-related industries such as accommodation, experience downturns with the commencement of oil and gas extraction. (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Housing

The rapid influx of people seeking work puts extreme pressure on housing and accommodation stocks. Evidence from the United States, Britain and Canada has identified a negative impact on local housing markets. For poorer residents, affordable housing becomes a challenge as there are insufficient houses available to satisfy demand. However, over the longer-term, the negative impacts of the industry, such as pollution and seismic activities, resulted in properties losing value – and these impacts tended not to be covered by home insurance. In some cases, some properties became 'unsellable' or people were unable to cover their home loans – especially during volatile periods (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Inequality

Evidence also indicates that the combined impact of these challenges exacerbates pre-existing social and economic problems within communities. In particular, inequality between residents tends to accelerate, between those who benefit from the non-renewable resource boom and those who do not, but nonetheless still have to endure its negative impacts. As the Concerned Health Professionals of New York note 'economists are increasingly quantifying community quality of life impacts and the unequal distribution of costs and benefits associated with drilling and fracking.' (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Conflict

There are numerous global examples of increased conflicts around non-renewable resource extraction sites, largely due to the degradation of natural resources. Indigenous communities are frequently at the forefront of this violence and intimidation (Lind, 2015). Examples include the convergence of state and corporate interests in driving non-renewable resource-violence in Nigeria, Mozambique, South Africa, Uganda and elsewhere. (Lyons, 2016). Another example comes the state-based violence currently being perpetrated against members of the North Dakota's Standing Rock Sioux Tribe who are trying to defend their water rights and way of life against the North Dakota access oil pipeline (Lind, 2015). Conflict also occurs as residents from regions where mineral resources are being extracted feel that they are not benefitting from them but are enduring the negative consequences of the extraction (Rose, 2015)

Babatunde (2020) notes that oil pollution of the marine environment and increased deforestation and the exploitation of marginal land has severely damaged the resources that people traditionally depended upon for their livelihoods in the Niger Delta. This has led to a complex pattern of conflicts in the region since the late 1990s. Local people blame the oil multinationals and the Nigerian government for the environmental degradation and feel they have not been properly compensated for its impact (Babatunde, 2020).

In Turkana, in northern Kenya, relations between the state and local communities are characterised by mistrust and conflict since the mushrooming of oil exploration operations in the area since 2012. Until the oil finds, successive governments showed little interest in Turkana, even though insecurity was rife and poverty levels were high. Many Turkana are dubious of the state's inability or unwillingness to address chronic violent insecurity, which has been so damaging to the livelihoods of local pastoralists over time. (Lind, 2015).

Local Employment

Evidence suggests that few jobs are realised for local community members in the early years of oil or gas developments. The Concerned Health Professionals of New York (2020) documented that in the USA, 77% of the workforce on shale gas drilling projects consisted of transient workers from out of state. Only by the 30th year of the shale gas development would 90% of the workforce be comprised of residents from in state (Concerned Health Professionals of New York; Physicians for Social Responsibility, 2020).

Local towns also suffer from the consequences of Dutch Disease when non-renewable resources become depleted or when demand shrinks. In these areas, finding employment with the extractive has often been the only means of survival. As a result of the decline in demand for coal, oil and gas, and the inevitable decommissioning of rigs, mining communities around the world have seen their local job markets decline or be eliminated entirely (SystemIQ, 2020). This obviously has the effect on exerting yet more pressure on local governments. (Raimi & Newell, 2016) warn that all communities heavily dependent on oil and gas-related revenues must diversify their economies – a major challenge when regional economies have come to thrive on the extraction of finite resources.

In South Africa, our high rates of unemployment will probably result in an influx of unemployed people into oil and gas rich locations who will likely increase the size of informal settlements, while housing and rental costs are likely to increase for middle-income families. Although local governments will probably gain from property taxes, residents will most likely carry the burden of the increased taxes in order to subsidise the increase in demand for municipal services.

The sad reality is that most municipalities in South Africa will be entirely incapable of dealing with the increases in demand for public services and environmental protection services that will come with the emergence of an oil and gas sector in South Africa. In 2020, the Auditor-General reported that 'most municipalities' in the country were in a state approaching chaos. They were 'crippled by debt', could not pay for water and electricity, had 'inaccurate and lacklustre revenue collection', and were plagued with 'expenditure that is unauthorised, irregular, fruitless and wasteful'. He concluded by noting that there was a 'high dependence on grants and assistance from national government' (Makwetu, 2020).

There are also important differing concepts of 'development' and what 'development' actually means to people. It cannot be assumed that all South Africans want the economically determinist development that resource extraction promises to bring. The current battles over mining in the Xolobeni region of the Eastern Cape in South Africa is insightful here.

Within the Xolobeni community many people are opposed to attempts by an Australian company to mine their traditional lands. Community members reject the type of development that they believe will come with mining. As Overy notes, 'they want to continue to use their unpolluted grasslands for pasture, grow their naturally organic food from their kitchen gardens and preserve the health of the rivers they drink from' (Overy, 2019). Xolobeni community leader, Nonhle Mbuthuma, stated last year, 'us and the land, we are connected. If you separate us from the land, you are killing some part (of us)'. (Rosa Luxemburg Stiftung, 2020).

Clearly these important concerns need to be considered within the context of the development of oil and gas in South Africa because much more than simple, reductionist economic views of the world are at stake.

Raimi & Newell (2016) argue that each community experiences oil and gas-driven growth differently and that it is difficult to generalise from one region to the next (Raimi & Newell, 2016). They note that a substantial majority of local governments across the United States have experienced net fiscal benefits from increased oil and gas production, and while they have seen increased demand for public services, revenue from a variety of sources has largely been more than enough to offset these additional costs. However, the data they present is concerning as they do not analyse losses from other industries, increased public health costs, increased pollution, nor do they weigh costs versus the revenue in their data. Moreover, they note that not all local governments have seen net fiscal benefits from oil and gas production. Municipalities that have experienced rapid growth have struggled to provide services for rapidly increasing populations (Raimi & Newell, 2016).

A South African Local Example: Platinum and the City of Rustenburg, South Africa

In Rustenburg South Africa, platinum output increased by 67% between 1994 and 2009, changing Rustenburg from an agricultural community to a more urbanized city (Lagercrantz & Khabbez, 2019; Eunomix, 2016). During this period, people migrated to Rustenburg to find jobs in the platinum sector which resulted in the population growing from about 68 000 in 1996 to 626 522 in the 2016. The most significant increase was among the male population in the 20 – 34 age group (Eunomix, 2016). So rapid was Rustenburg's growth, that by 2012 it contributed almost 4.9% of South Africa's GDP (Eunomix, 2016). However, the economy of Rustenburg became dependent on supporting the mining industry, which accounted for 70% of all local businesses (Lagercrantz & Khabbaz, 2019; Eunomix, 2016).

At the local level, the impact of the platinum boom has been largely negative. The rapid increase in population density has led to numerous social challenges, as documented by Eunomix (2016), Lagercrantz & Khabbaz (2019), and the Bench-Marks Foundation. These social challenges include:

- **Unemployment** - In 2011, overall unemployment in Rustenburg was 26.4%, with youth standing unemployment at 35%. Furthermore, 30% of the economically active population earnt no income, while 24% of households lived on less than ZAR 600 per month.
- **Crime** - Overall levels increased as more thefts, sex crimes, drug-related crimes and residential burglaries take place in Rustenburg than in other South African cities of similar size.
- **Disrupted Households** - Increased numbers of single men, and female-headed households (27% of all households), which has resulted in increased poverty as women struggle to find work due to patriarchal structures (Eunomix, 2016).
- **Substantial increases in HIV and AIDS rates** - between 2001 to 2011, there was a 49% increase in the number of HIV-infected people in Rustenburg. Other health problems among mine workers include tuberculosis, malnutrition, and respiratory illnesses. High levels of substance abuse have also been reported.
- **Lack of access to quality formal education.** The influx of people has resulted in overcrowded schools (up to 65 children per class) and a lack of basic schooling infrastructure. Moreover, only 31% of Rustenburg's population aged over 20 have completed high school, and only 8.9% have some form of higher education.
- Significant poverty levels and income inequality threaten social cohesion as almost 62% of the population live in poverty.

Evidence shows that the local government is unable to meet the demand for basic services such as housing, water, electricity, sewerage, public transport, health facilities

and schools. This inability to meet with the demands for social goods has been hampered by the mismanagement of local public finances, inadequate government capacity, and questionable policy decisions.

9. Additional Economic Risks to Consider

1. Increasing Sovereign Debt and Fiscal Risk

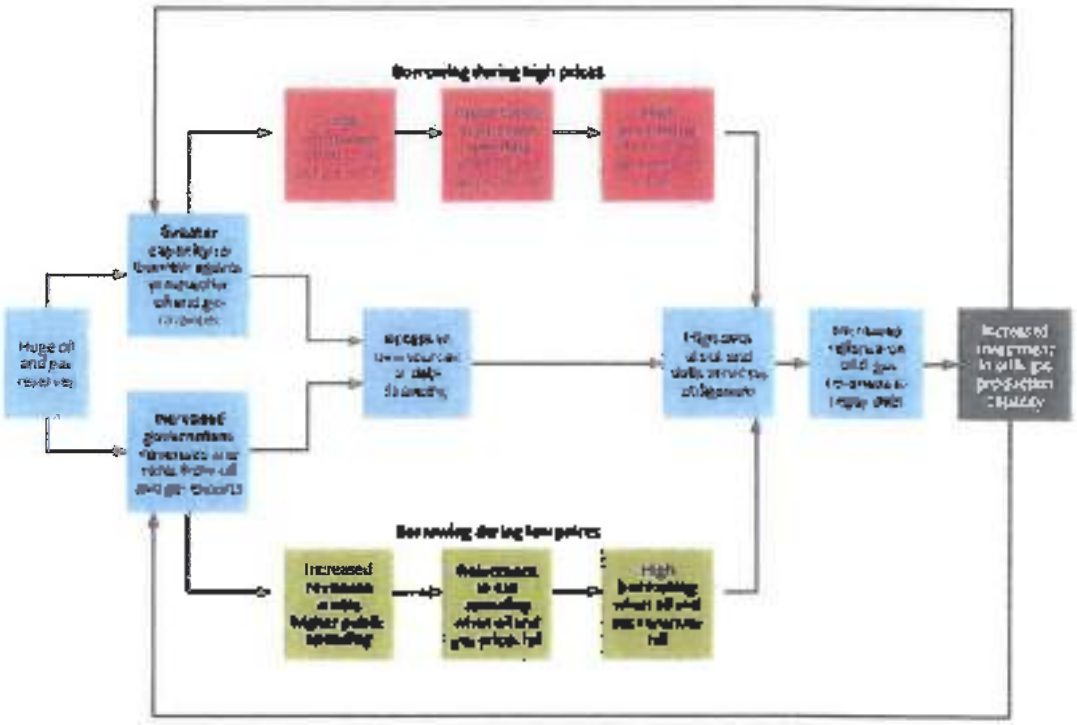
African debt, both continentally and nationally, has been rising (UNCTAD, 2023). In 2022, public debt in Africa reached USD1.8 trillion, increasing by 183% since 2010 (UNCTAD, 2023)[5]. Steadman, et al (2023) note that the increase in sovereign debt levels in low- and middle-income countries can't only be attributed to oil and gas dependency however their findings indicate that **oil and gas production exacerbates fiscal risks.** For oil and gas producers, the risks associated with climate change are high because of both the physical impacts of climate change and the likelihood of disappearing export markets will lead to fiscal and macroeconomic instability (Steadman, et al. 2023).

Petrostates tend to have increased fiscal dependence on oil and gas revenue (i.e. more dependent on the income from exporting oil and gas). Of the 33 petrostates for which the IMF has consistent data, average central government debt nearly doubled from 24% of GDP in 2010 to 46% in 2018. And the assumption was that this debt would increase (Steadman, et al. 2023). **Petrostates tend to borrow both when the oil price is high** because their credit ratings rise and hence make cheaper finance available, **and when it is low**, in order to fill their resulting fiscal gaps (Steadman, 2023). Their diagram below illustrates how countries become locked into debt dependency. Prince et al (2023) **warn that the energy transition will further exacerbate the levels of sovereign debt** as countries credit ratings decline and debt becomes more expensive while also seeing revenue from oil and gas falling and debt servicing becoming more important.

[5] The heavy debt-repayment burden will impact negatively on economic growth and stability in countries (Economist Intelligence, 2023). The higher borrowing costs and increasing debt have reverberated across countries' ability to finance development (and climate-related disasters) (UNCTAD, 2023). A higher share of revenue dedicated toward debt servicing is problematic in that it diverts resources from areas Africans need most including health, education, development and social support, exacerbating the situation of Africa's vulnerable populations. UNCTAD (2023) adds: As Africa's debt continues to rise, the continent is being confronted with a global financial architecture that is misaligned with its needs.

Figure 8: How oil and gas production locks nations into indebtedness and further dependency (Source: Steadman et al 2023)

Figure 8: How oil and gas production locks nations into indebtedness and further dependency



South Africa's debt has ballooned and is approximately 74% of GDP (around R5.2 trillion) (Van Niekerk, 2024). Debt is expected to increase to 77.7% of GDP in the 2025/26 fiscal year, exceeding R6 trillion (debt was R2.3 trillion or 49% of GDP in 2018) (SANews.gov.za, 2023). This limits government's ability to channel resources into the productive side of the economy as debt service costs are crowding out social spending as debt repayments form a greater share than social protection, health, community development, or economic development, with one in every five rands being spent on servicing the debt (Marais & Spangenberg, 2024; Van Niekerk, 2024; SANews.gov.za, 2023).

If SA has to take out further loans to develop an O&G sector, our debt and debt repayments would rise substantially – likely leading us to default on debt repayments and to shift into a full economic recession. Given this debt crisis, serious questions need to be asked about whether it is prudent to be investing in volatile commodities like oil and gas which could become a serious financial burden on the South African economy. There is little doubt that investing in oil and gas in South Africa is risky and has the potential to increase the country's already excessive debt burden.

2. Downgrading of credit ratings

> ... credit rating agencies, have all moved to the arena of comprehensive credit analysis, acknowledging the impact of climate change on traditional risk areas—regulatory, legal, economic, financial, political, and social. The issue has grown to such magnitude that climate has become its own risk category. (Sanzillo 2024).

Credit ratings are described as **independent mechanisms to assess creditworthiness** or the ability – and willingness – of **debt issuers to meet repayment obligations** (Steadman, et al. 2023, Sanzillo 2024). Credit ratings provide international investors with a rapid, standardised way to assess and price debt, and are particularly important for borrowing in international capital markets. But credit ratings agencies have significantly changed their perspectives: **fossil fuels** were once considered to be credit positive but now they are issuing clear, **specific warnings about the financial risks of fossil fuels** including oil and gas as these now face substantial financial risks.

Prince, et al. (2023) find that **there has been a general downgrade in credit ratings for the petrostates as debt has increased.** As petrostates earn less revenue from their oil and gas production, their **creditworthiness declines** i.e. they will have **lower credit ratings and thus borrowing on international capital markets will become more expensive** for these petrostates (Prince, et al. 2023). The consequences are likely to be a devaluation of currency, rising debt levels, reduced access to capital markets and economic contraction leading to concerns among investors and credit rating agencies about a state's ability to service its debt i.e. lower investor confidence (Prince, et al. 2023). Sanzillo (2024) warns that countries that want to capitalise on not yet exploited oil and gas reserves, **the market is more likely to reward low-carbon, fossil-free investments** (Prince, et al., 2023).

A key factor that prospective lenders typically use to assess the creditworthiness of a sovereign government, state-owned entity or private company that controls significant oil and gas reserves is the market price of oil and gas (S&P Global Ratings, n.d.). This is because the entity's ability to service debt is linked to the revenues it can generate from the sale of oil and gas, which are higher when prices rise and lower when they fall. However, commodity markets experience large and unpredictable price fluctuations (Steadman, et al., 2023). Thus, experience indicates that revenues tend to not be predictable.

Figure 2: Credit ratings agencies evaluations of fossil fuel sources

South Africa's credit ratings have been somewhat volatile over the last decade. In January 2024, Fitch credit rating agency disappointed SA by affirming the rating BB- with a stable outlook i.e. indicating an elevated vulnerability to default risk. In May 2024, S&P left SA's rating at S&P has a "BB-/B" rating on South Africa's foreign currency debt and a "BB/B" on local currency debt. These ratings are lower than investment grade ratings, making it more expensive to borrow on international markets for SA.

However, ratings agencies have expressed concern due to the weak economic outlook; power shortages, the struggling logistic sector, high unemployment rates and income inequality, and a high and rising government debt-to-GDP ratio. But the ratings agencies identified positive aspects such as flexible exchange rates, mostly local-currency-denominated, strong institutions, as well as a credible central bank. Were South Africa to increase its debt-to-GDP ratio further, credit would become far more expensive making it challenging to borrow on international markets.

3. Technological Lock-In

If African countries continue to invest in fossil fuels, it will displace investment in clean energy systems – Africa will be locked into old technologies and infrastructure and will be unable (and unaffordable) to change its course (Dube, No date). In 2022, RES4Africa wrote that although Africa's energy system has seen a major transformation, there has been limited uptake of non-hydro renewables. They add that if sustainable energy solutions had played a greater role in the transition from coal, there would have been the opportunity to significantly increase the socio-economic benefits that would have accrued with their development (RES4A; IRENA; UNECA, 2022). In addition to benefits such as the speed and reduction in operational costs of renewable energies, the positive impacts of shifting to renewable energy include:

- For each dollar invested, renewable energy creates two to five times more jobs than fossil fuels
- Other investments for a green economy – like climate adaptation, conservation agriculture, public transport and energy-efficient building retrofits – provide up to 25 times more jobs than those created by fossil fuels (IRENA and AfDB, 2022).

Reff, et al. (2022) note that the economically rational role for gas in power generation is for peaking or standby capacity. For approximately 97% of the time, large-scale gas-fired power generation will stand idle. Thus, locking SA into energy systems largely reliant on gas will create technological lock-in and perverse outcomes. Investing in gas infrastructure would reduce the funding available for cheaper RE and due to the cost of gas, if there is an extensive gas build out, including CCGT, it will be expensive to run these systems (and increase overall costs of energy in SA, likely to be passed onto consumers). Moreover, 'The option to delay this decision has immense value for South Africa, allowing us to evaluate technological developments as they arise and not commit ourselves to carbon lock-in / stranded assets.' (Reff, et al. 2022).

4. Illicit financial flows

   Countries with a high level of dependency on oil are more prone to higher levels of IFFs. (UNCTAD 2020).

Illicit financial flows (IFFs) are methods, practices and crimes aimed at **transferring financial capital out of a country, in contravention of laws. IFFs** include money laundering, bribery and tax evasion (Global Forum Secretariat, 2023). IFFs erode the public revenues that countries need to invest in their social and economic development, erode the investment base of countries and undermine the public's confidence in the integrity of the tax system (OECD, 2022).

Although it's difficult to accurately track IFFs, the report on Tax Transparency in Africa (2023) notes that IFFs as much as 50% of illicit outflows from Africa are generated via trade mispricing. In 2019, it was estimated that Africa loses more than $50 billion annually in IFFs although estimates vary with UNCTAD (2020) estimating that Africa had IFFs of USD 88.6 billion (EUR 85.1 billion) annually, or 3.7% of Africa's gross domestic product (UNCTAD 2020). IFFs are substantially higher than aid and investments in Africa (Global Forum Secretariat, 2023; ECA, 2019).

Research indicates that the **extractive industries are particularly prone to IFFs** (UNCTAD 2020). This is because the extractive industries tend to have high degrees of power and political influence, as key areas of revenue and export earnings, and African countries enter into secret and unequal contracts with multinational companies i.e. a **lack of transparency and accountability** (ECA 2019, Global Forum Secretariat 2023).

Of explicit concern is that IFFs contribute to financing terrorism in Africa:

> Taken together, the illicit exploitation of natural and environmental resources, including gold, diamonds, oil, charcoal, other minerals, timber and wildlife, and illegal taxation, confiscation and looting, account for 64 per cent of finance linked to security threats and conflicts (International Criminal Police Organization et al., 2018). It is further estimated that of the $31.5 billion in IFFs generated annually in conflict areas, 96 per cent is used by organised criminal groups, including to fuel violent conflict (Global Forum Secretariat 2023).

Illicit financial flows (IFFs) are difficult to measure due to their secrecy but it has been estimated that South Africa is losing more than $62 billion a year because of illicit financial flows and tax evasion: $21.9 billion per year in inward flows and $40.9 billion in outward flows (Cokayne, 2023). OECD research indicates that IFFs, not including tax evasion, might be closer to **between USD 3.5 and 5 billion in IFFs are leaving the country each year** (approximately 1-1.5% of South African annual GDP).

IFFs are particularly harmful in South Africa due to the significant fiscal challenges that the country faces. The SA government is trying to effectively address IFFs in SA but this is challenging without sufficient capacity and global support (OECD, 2022). A study on the Illicit Financial Flows (IFF) in the South African mining sector, specifically analysed transfer pricing (TP). The research noted that Trade misinvoicing is a reality impacting the South African mining industry and trade misinvoicing has become normalised in many categories of international trade. This form of IFFs which reduces the ability of SA to capture its legitimate share of the gains from international trade in terms of foreign exchange earnings and fiscal revenue collected from customs and other trade levies. At the same time there are many incentives for trade misinvoicing due to the regulatory environment (tariffs, customs, export subsidies, exchange controls) and imperfect monitoring and poor enforcement of regulations (Ngozo, 2020). Trade misinvoicing generates two sets of losses to the economy:

- Loss of revenues from customs duties, VAT taxes, income taxes, royalties, and other measures.
- Perpetuating the current economic structure through transfers of income and wealth out of domestic earnings, usually into wealthier countries overseas.

The South African mining industry has accumulated and reported net profits of R221 billion, between 2010 and 2019. The declared profits do not include the undeclared IFFs in trade misinvoicing for the silver-platinum group (R296 billion) and iron ore (R108 billion) in 2014 alone (Ngozo 2020). It is likely that IFFs will take place in an O&G sector

in SA where it is difficult to govern and measure extraction of O&G – which further impacts on the lack of profitability of an O&G sector.

5. Trade and competitiveness

According to the National Planning Commission, South Africa's trade accounts for around 60% of GDP (National Planning Commission, 2020). In light of the importance of trade to South Africa, remaining competitive is a particularly important economic factor. In 2020, Montmasson-Clair analysed the impact of the rise of the global climate change regime on South Africa's trade and competitiveness. The findings are highly concerning for South Africa's industrial development and that exports, are at particular risk. The reasons are:

- South Africa's exports are focused on a few destinations and they are heavily concentrated around a small number of value chains. Thus, South Africa is vulnerable to changes in trade patterns arising from measures aimed at transiting to low-carbon pathways.

- Secondly, many of the importers are transitioning away from carbon-intensive pathways, and consequently many of these importers are considering imposing a carbon border adjustment mechanism (carbon border tax) that would reflect the amount of carbon emissions attributed to goods imported into the region creating challenges for industries and countries with a large carbon footprint. This is a form of green protectionism where the justification of trade protectionist measures under the guise of addressing climate change and environmental goals. South Africa's exports are already more carbon intensive due to our carbon-intensive energy system and the country is a large exporter of fossil fuels. Moreover, SA's vulnerability is reinforced by the absence of an ambitious climate change framework.

- Finally, South Africa's relatively long distance to its trading partners has implications for transport costs and associated GHG emissions (PWC, 2020; Montmasson-Clair, 2020).

Border Carbon Adjustments (BCA) are **climate measures to prevent the risk of carbon leakage** (i.e. the movement of production and associated emissions between countries due to different levels of decarbonisation effort through carbon pricing and climate regulation) and is designed to **support increased ambition on climate mitigation** (Monaisa & Maimele, 2023). The EU's BCA, known as the Carbon Border Adjustment Mechanism or CBAM, came into effect in October 2023. The UK is also planning a BCA (Maimele, 2024). The impact of CBAs will be determined by the **carbon embedded production in goods that are traded.** Thus, if we decarbonise our electricity systems more, the CBAs will have less impact on African countries (Monaisa and Maimele 2023).

The **EU CBAM** is a tax on embedded emissions for goods imported into the EU that emit more GHG emissions than allowed for EU manufacturers under the EU Emissions Trading System (ETS). Initially, the CBAM will apply to direct emissions from sectors identified as at risk of carbon leakage, i.e. electricity, cement, fertilisers, steel and aluminium (Monaise and Maimele 2023). The **UK CBAM** is also a carbon tax paid on high emitting exports to the UK and mirrors the EU CBAM with less electricity plus ceramic and glass to its sector coverage (Maimele, 2024).

The EU CBAM will have a larger impact on African countries, as a share of GDP, than all other regions because the EU is an important trade market for African countries and several export commodities from Africa are relatively more carbon intensive than other countries (accounting for 26% of Africa's exports of fertiliser, 16% of iron and steel, 12% of aluminium and 12% of cement) (African Climate Foundation; The London School of Economics and Political Science, 2023). In the long run, **EU CBAM is forecast to reduce African exports to the EU by -5.7% and continental GDP by -1.1%** (equivalent to a $16 billion reduction in GDP at 2021 levels the GDP of the continent by 0.91%, although CBAM is forecast to reduce the GDP of no single African country by more than 0.18% (African Climate Foundation; The London School of Economics and Political Science 2023). A number of African Least Developed Countries would be among the most affected, notably Gambia and Mozambique (African Climate Foundation; The London School of Economics and Political Science 2023).

Analysis by TIPS notes that under the EU CBAM, a total of US$2.4 billion (about R45.4 billion) of South African exports (based on 2023 data) is at risk in the short term. This is about 11.3% of all South African exports to the EU, and about 2.2% of total South Africa exports to the world, and 0.7% of total South African GDP (Maimele, 2024). The UK CBAM would have a smaller impact but would likely result in a total of US$223 million (About R4.3 billion) of South African exports (based on 2023 data) being at risk in the short term. This is about 4.2% of all South African exports to the UK, and about 0.2% of total South Africa exports to the world, and just 0.1% of total South African gross domestic product (GDP). Fertilisers, iron and steel as well as aluminium are primary goods in jeopardy (Maimele, 2024).

TIPS offers recommendations for SA to reduce the impact of CBAs on our exports:

- Decarbonising industries: Companies and government should accelerate the decarbonisation of these carbon-intensive industries. Increasing renewable energy in production processes and investing in energy-efficient technologies will serve to decarbonise industrial sectors.

- Decarbonising South Africa's electricity system: South Africa's over-reliance on coal as a feedstock for electricity and liquid fuels production makes it one of the most carbon-intensive economies in the world. Increasing renewable energy in the national grid will decrease the indirect emissions of sectors that consume large amounts of electricity.

- Introducing more ambitious climate-change policies: South Africa's climate-change policies are not ambitious by global standards. An ambitious national climate change policy is required to steer the country towards a low-carbon development trajectory.

- Reforming South Africa's carbon tax to reflect global carbon pricing will be critical to ensure that the country's carbon-intensive products reflect the social price of carbon. Increasing the South African carbon price will stimulate heavy emitters to reform their business models and operations (Monaisa and Maimele 2023).

If indirect emissions are included in future, South African exporters will face additional risks as the country is heavily reliant on coal for its electricity and liquid fuels (Monaisa and Maimele 2023). Thus, to ensure our exports are as competitive as possible in SA, we can't afford to invest in any further fossil fuels but should focus on transitioning to net zero (Roff, et al. 2022).

6. Financial Flows and Ownership

"This debt will be paid by generations" Sokhna Ba

The financing and ownership of fossil fuel extraction and production in Africa is largely from the global north (Dube No date):

- Between 2016 and 2021, approximately $132.3 billion of investment in fossil fuel companies and projects in Africa, largely from financial institutions from North America, Europe, and Australia

- An estimated 61% of the projected production in Africa between now and 2050 is owned by multinational companies headquartered in Europe, North America, and Asia (Deley, 2023).

The implication of this is that **the profits of the financing tend to accrue to countries in the global north** (Dube No date). At the same time, **African governments and citizens tend to hold the risk** – partially due to the risk of **stranded assets, poor contractual terms** given to African governments and the risk of developing countries becoming liable to pay compensation to private sector fossil fuel companies under **investor** law with the legally binding Energy Charter Treaty which supports investor confidence in part with mechanisms for investor–state dispute settlement (ISDS). The contracts that African

governments get into with investors from the global north need to be scrutinised to avoid risks that come with stranded assets. These contracts would be better off had most of the risks been borne by investors from the global north (Dube No date). Following the ExxonMobil court case in Guyana in 2023, which despite the environmental impact statement for the Guyana project identifying 12 islands with a gross state product of $147 billion that could be affected by an oil spill, ExxonMobil has failed to provide adequate oil spill coverage and insurance and yet will only be liable for $2 billion damage and the rest of the liability for any potential oil spill has been shifted back onto the people of Guyana.

7. The social costs of carbon

The social cost of carbon (SCC) is an estimate of the cost of the damage done by each additional ton of carbon emissions. It also is an estimate of the benefit of any action taken to reduce a ton of carbon emissions. (Asdourian and Wessel 2023). The SCC is used to assist policymakers to evaluate the impact of policies. Recent research by Bilal and Känzig (2024) estimates that the macroeconomic damages from climate change are six times larger than previously thought. They find that a 1°C increase in global temperature leads to a 12% decline in world GDP (Bilal and Känzig 2024). Using a standard neoclassical growth model, research identifies a Social Cost of Carbon of $1,056 per ton of carbon dioxide (Bilal and Känzig 2024). Both are multiple orders of magnitude above previous estimates.

The International Institute for Sustainable Development (IISD) finds in a report on South Africa's energy fiscal policies, that the social cost of fossil fuel combustion for South Africa is at least R550-billion a year and exceeds, by five times, the revenues government earns from fossil fuel combustion. The social cost includes deaths, disease and working days lost owing to air pollution and greenhouse gas (GHG) emissions. https://www.engineeringnews.co.za/article/social-cost-of-using-fossil-fuels-much-higher-than-govt-gains-study-shows-2022-01-31

8. Decommissioning costs

It is important to include the cost of decommissioning of offshore oil and gas infrastructure upfront in all financial decisions – otherwise these costs will be borne by the state and ultimately, by the South African taxpayers. For instance, the total cost of decommissioning UK offshore oil and gas production, transportation and processing infrastructure is estimated to cost £46bn (Oil & Gas Authority, 2020). Australian research highlights the importance of minimising impacts from contaminants when decommissioning infrastructure as these contaminants could escape into the wider environment – with additional costs attached to cleaning these up (Dawkins, 2020).

10. Conclusion

The analysis presented in this literature review underscores the multifaceted implications of continuing to invest in fossil fuels in South Africa. Despite the push from leaders for oil and gas to foster economic growth, the evidence suggests that this path is fraught with significant risks—not just economically, but also socially and environmentally. As the global energy landscape evolves and more nations commit to reducing carbon emissions, South Africa's reliance on fossil fuels threatens to exacerbate existing challenges, including economic instability, social inequality, and environmental degradation.

The emerging realities of transition risks, stranded assets, and climate impacts compel a reevaluation of energy policies and investment strategies. Africa possesses the potential to be a pioneer in renewable energy development, allowing for a sustainable economic future that prioritizes equity and environmental integrity. Therefore, the time to act is now; a shift towards renewable energy sources is not only imperative for mitigating climate risk but also vital for ensuring that the hopes and aspirations of all South Africans are met, fostering a resilient and equitable energy future for the continent.

IN THE HIGH COURT OF SOUTH AFRICA

(WESTERN CAPE DIVISION, CAPE TOWN)

Case No ...../2024

In the matter between:

AUKOTOWA FISHERIES PRIMARY CO-OPERATIVE LIMITED	First Applicant
THE GREEN CONNECTION NPC	Second Applicant
NATURAL JUSTICE	Third Applicant

and

DIRECTOR-GENERAL: DEPARTMENT OF MINERAL AND PETROLEUM RESOURCES	First Respondent
MINISTER OF FORESTRY, FISHERIES AND THE ENVIRONMENT	Second Respondent
TGS GEOPHYSICAL COMPANY (UK) LTD	Third Respondent
MINISTER OF MINERAL AND PETROLEUM RESOURCES	Fourth Respondent

---

EXPERT AFFIDAVIT : MARK NEW

I, the undersigned,

MARK NEW

do hereby make oath and state:

MN

1. I am a professor in the Department of Environmental and Geographical Science at the University of Cape Town and the previous director of the African Climate and Development Initiative (2011 – 2023).

2. The facts contained in this affidavit fall within my own personal knowledge, except where I indicate otherwise and are, to the best of my knowledge, true and correct. To the extent that I rely on information supplied by others, I believe that such information is true and correct.

3. I have over twenty-five years of experience in climate change research, teaching and project management. My qualifications and experience are set in my curriculum vitae, a copy of which is attached marked '**MN1**'. By virtue of my qualifications, training and experience, I submit that I am qualified to give expert evidence on the issues traversed in this affidavit.

4. In order to arrive at a balanced assessment of whether or not the exploration for, and production of, oil and gas in South Africa is socially, environmentally and economically sustainable, it is necessary to consider, assess and evaluate the social, economic and environmental impacts of those activities, including disadvantages and benefits. In this affidavit, I set out the basic science underpinning concerns about climate change and the global and national efforts to arrest this phenomenon, and some of the considerations relevant to deciding whether or not to authorise gas exploration and production in South Africa. I point out that authorising those activities would be at odds with South Africa's climate change policies and its international commitment to dramatically reducing greenhouse gas emissions. It would also exacerbate the extent of climate change and thereby contribute to very significant adverse impacts on

people (especially women, vulnerable people and future generations) and the environment.

Paris agreement limits

5. As a party to the United Nations Framework Convention on Climate Change ("**UNFCCC**") and the Paris Agreement, South Africa has agreed to collaborate with the other Parties to limit the increase in the global average temperature to well below 2°C above pre-industrial levels, and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels. This requires South Africa to do its "fair share" of reductions in the emissions of greenhouse gasses ("**GHGs**"). South Africa has acknowledged this in its first (2016) and updated (2021) Nationally Determined Contribution ("**NDC**") submissions to the UNFCCC, where (in the latter) it states it has committed "to ultimately moving towards a goal of net zero carbon emissions by 2050, which will require various interventions to reduce greenhouse gas emissions".

6. Climate change is already having very significant negative impacts on people and ecosystems throughout the world, including in South Africa. The significance of the Paris Agreement target of 1.5°C above pre-industrial levels is that it reflects a global consensus that the level of risk to humanity becomes unacceptably high once that threshold is crossed. Those include the risk of extremely high impact "tipping point" changes in the climate which I discuss below.

MN

Remaining Carbon Budget

7. The cumulative "stock" of GHGs (particularly CO_2) in the atmosphere is the primary driver of long-term global warming. This means that even if all human-caused GHG emissions ceased immediately, Earth's climate would still heat up by several tenths of a degree Celsius because the GHGs which are already in the atmosphere will continue warming in the Earth's climate for more than a century.

8. The 'Remaining Carbon Budget" is the amount of CO_2 that can be emitted in the future, while still keeping human-induced warming below 1.5°C or 2.0°C. The remaining carbon budget is not a single number, but a range of budgets each of which corresponds to a specific likelihood of keeping global warming below 1.5 °C or 2.0°C. For example, the IPCC's Sixth Assessment Report published in March 2023 estimated that in order for there to be a 50% likelihood of limiting warming to 1.5°C, the remaining carbon budget from the start of 2020 was 500 Gt (Gigatonnes) CO_2.

9. However the Remaining Carbon Budget is shrinking fast. The Indicators of Global Climate Change ("IGCC") initiative produces estimates for key climate indicators that are consistent with the IPCC's Sixth Assessment Report.[1] The IGCC's updated assessment has determined that the remaining carbon budget has reduced from 500 Gt CO_2 at the start of 2022 to 200 Gt CO_2 as of November 2024. This is largely due to the annual emissions of around 55 Gt CO_2 per year over the last four years. My own estimates, which are more conservative (and therefore generous), place the current remaining carbon budget at 380 Gt CO_2.

[1] See Current Remaining Carbon Budget and Trajectory (climatechangetracker.org)

2 of MN

Using either determination, this means that the window of opportunity within which humanity can take measures to avoid overshooting the 1.5°C and 2.0°C thresholds for dangerous, and perhaps catastrophic, climate change, is closing fast.

Proven oil and gas reserves far exceed what can be combusted

10. I have prepared the report attached to this affidavit, marked '**MN2**', and confirm that to the best of my knowledge and belief the contents of that report are true and correct.

11. As I explain in that report, as a matter of scientific fact, the total proven oil and gas reserves globally exceed by some margin what it would be possible to combust while still implementing the global GHG emissions reductions necessary to limit the increase in global average temperatures to no more than 1.5°C above pre-industrial levels. Proven coal reserves, if burned, would result in additional emissions more than double those from oil and gas. Investing in more oil and gas exploration and new resource discoveries will inevitably lead to greater production and greater GHG emissions at a time when it is critical to reduce emissions.

12. The abovementioned report shows that the remaining amount of global GHG emissions (specifically CO_2) that can be emitted (as of November 2024) and still have a reasonable (50:50) chance of keeping global mean temperature below 1.5°C is 380 Gt CO_2. Similarly, remaining emissions of CO_2 that would have a reasonable chance of keeping "well below" 2.0°C are 920 Gt. Both of these remaining CO_2 budgets far exceed the emissions that would arise from combustion of already discovered coal, oil and gas, which conservatively, are

2.12 MN

estimated to be 1540, 543 and 350 Gt CO_2, respectively, or 2,433 Gt CO_2 combined. Therefore, today, the extent to which discovered reserves exceed what can be burned while keeping global temperature increases below 1.5°C is already significant, and increases each year by approximately 50 Gt CO_2 as GHG emissions continue.

13. The analysis in my report is echoed in other work. For example, based on a review of selected climate and energy scenarios by intergovernmental organizations, including the IPCC, the International Renewable Energy Agency (IRENA) and the International Energy Agency (IEA), the International Institute for Sustainable Development (IISD) noted a consensus that no new oil and gas fields should be developed if the world is to achieve the 1.5°C target[2]. Similarly, in 2021, the International Energy Agency declared that "there is no need for investment in new fossil fuel supply" in its scenario for achieving net zero emissions by 2050 – a finding it reiterated again in 2023[3].

14. The IPCC's Sixth Assessment reports also show that reducing emissions is no longer sufficient, and that it will also be necessary to remove some of the carbon that is already in the atmosphere or will be in the atmosphere in the years to come.

> *"From a physical science perspective, limiting human-caused global warming to a specific level requires limiting cumulative CO_2 emissions, reaching at least net zero CO_2 emissions, along with strong reductions in other greenhouse gas emissions. Reaching net zero GHG emissions primarily requires deep*

[2] International Institute for Sustainable Development, Navigating Energy Transitions: Mapping the Road to 1.5°C (Oct. 2022), p.16. https://www.iisd.org/system/files/2022-10/navigating-energy-transitions-mapping-road-to-1.5.pdf.

MN

reductions in CO2, methane, and other GHG emissions, and implies net negative CO2 emissions. Carbon dioxide removal (CDR) will be necessary to achieve net negative CO_2 emissions […]."[4]

The fact that CDR, which is as yet unproved at scale, will be required over the next 25 years to reduce CO_2 levels in the atmosphere to meet the Paris temperature targets, reiterates the need to reduce future GHG emissions as steeply as possible.

Impacts of climate change and tipping points

15. It is important to appreciate that climate change is not linear, and its impacts not necessarily reversible. Non-linear impacts of climate change have been termed "tipping points". A climate tipping point occurs when change in one or more large parts of the climate system change rapidly (or "tip") once a particular global warming threshold is exceeded. Once such a tipping point has been passed, the change will continue regardless of how humans respond, causing so-called 'irreversible' climate change.

16. An example of a climate tipping point is melting of the Greenland Ice Sheet. At somewhere between 1.5 and 2.0 °C global warming, summer melting will exceed winter accumulation of the ice sheet, and its mass balance starts to decrease. As its mass decreases, the elevation of the ice sheet (currently up to 3,300m above sea level) decreases, and surface temperatures become warmer due to this lower elevation (the lapse rate effect). Even if global warming is reversed, the lower elevation and warmer temperatures ensure that melting continues in a positive feedback loop. Complete melting of the

[4] B.5.1

Greenland Ice Sheet will cause ~6m of sea level rise, inundating nearly all coastal settlements, including those in South Africa, such as Cape Town and Durban.

17. Some tipping points can act to increase GHG emissions, further accelerating climate change. For example, the Amazon forest is projected to collapse and transform into a savanna landscape somewhere around 2.0 °C. The carbon stored in the forest vegetation and soils will be released into the atmosphere as GHGs, adding to those from fossil fuels, and the capacity of this new savanna ecosystem to act as a sink for CO_2 will be much lower than the forest it replaced. This creates "positive CO_2 feedback" which causes the change to accelerate and become self-perpetuating.

18. An article titled "*Exceeding 1.5°C global warming could trigger multiple climate tipping points*" published by leading climate change scientists in Science on 9 September 2022[5] states the following:

> "*Potential causal interactions among tipping elements are such that overall tipping of one element increases the likelihood of tipping others, possibly risking a "tipping cascade" of impacts that may further amplify global warming. In the worst-case scenario, interactions might produce a global CTP.*"
>
> "*The Earth may have left a safe climate state beyond 1°C global warming. A significant likelihood of passing multiple climate tipping points exists above ~1.5°C, particularly in major ice sheets. Tipping point likelihood increases further in the Paris range of 1.5 to <2°C warming. Current policies leading to ~2 to 3°C warming are unsafe because they*

[5] Armstrong McKay et al. 'Exceeding 1.5°C global warming could trigger multiple climate tipping points' Science 377, 1171 (2022) p.1

2.2 MN

would likely trigger multiple climate tipping points. Our updated assessment of climate tipping points provides strong scientific support for the Paris Agreement and associated efforts to limit global warming to 1.5°C."[6]

19. **The Summary for Policy Makers, which the IPCC published with its Sixth Assessment Report on global warming, was approved by government signatories to the UNFCCC, including South Africa. It recorded that human activities are causing an increase in the Earth's temperature, and this poses a risk to health, livelihood, food security and water supply, among others. The following extracts are relevant.**

"In the near term, every region in the world is projected to face further increases in climate hazards (medium to high confidence, depending on region and hazard), increasing multiple risks to ecosystems and humans (very high confidence). Hazards and associated risks expected in the near term include an increase in heat-related human mortality and morbidity (high confidence), food-borne, water-borne, and vector-borne diseases (high confidence), and mental health challenges (very high confidence), flooding in coastal and other low-lying cities and regions (high confidence), biodiversity loss in land, freshwater and ocean ecosystems (medium to very high confidence, depending on ecosystem), and a decrease in food production in some regions (high confidence). Cryosphere-related changes in floods, landslides, and water availability have the potential to lead to severe consequences for people, infrastructure and the economy in most mountain regions (high confidence). The projected increase in frequency and intensity of heavy precipitation (high confidence) will increase rain-generated local flooding

[6] Armstrong McKay et al. 'Exceeding 1.5°C global warming could trigger multiple climate tipping points' Science 377, 1171 (2022) p. 8.

2.2 MP

(medium confidence). (Figure 3.2, Figure 3.3, 4.3, Figure 4.3) (Figure SPM.3, Figure SPM.4)"[7]

'Risks and projected adverse impacts and related losses and damages from climate change will escalate with every increment of global warming (very high confidence). They are higher for global warming of 1.5°C than at present, and even higher at 2°C (high confidence). […]"[8]

20. Climate change is having, and will continue to have, disproportionately severe impacts on South Africa, and on poor and marginalised communities, women, children and future generations. The South Africa government acknowledges this. For example, the Just Transition Framework states:

> *'South Africa is in a part of the world that is severely impacted by climate variability. The country frequently experiences droughts, floods, and other extreme weather events, with evidence that the frequency and intensity of such events are increasing because of climate change (IPCC 2022). These events have already caused enormous damage to infrastructure, ecosystems, lives, and livelihoods, and displaced thousands of people, and continue to be a stark reminder that it is poorer communities—women and young people, the unemployed, those living in informal settlements— that are most vulnerable to climate change.'*

South Africa's emissions and remaining carbon budget

21. South Africa's GHG emissions are relatively high and the Union of Concerned Scientists estimated that in 2016 South Africa was the world's 13th biggest emitter of CO_2, and the largest in Africa. South Africa's per capita emissions of GHGs are also high by African standards. According to Climate Watch, South

[7] B2.1
[8] B2.2.

Africa's per capita emissions are 9.01 tonnes of CO_2-eq[9] and while Nigeria's is 1.83 tonnes CO_2-eq.

22. South Africa's remaining carbon budget, if it were to meet its self-defined "fair share" contribution to net zero global GHG emissions by 2050 is in the range of 6-9 Gt CO_2-eq[10]. At current annual emissions of ~455 Mt CO_2-eq, this budget will be exhausted within between 13 and 20 years (2037 - 2044). Thus, the country is already challenged to not exceed its nationally defined remaining carbon budget.

23. If a gas field were to be developed as a deep-water field, and over a ~15 year period it produced between 5 Tcf[11] and 10 Tcf of gas (approximately the minimum viable reserve size for offshore exploration at these depths), the combustion of that gas would release between 258 (5 Tcf) to 564 (10 Tcf) Mt CO_2-eq.

23.1. Those emissions will consume part of South Africa's remaining global carbon budget. By way of illustration, if the total amount produced were to be combusted in South Africa, this would consume a significant amount (3-9%) of the country's remaining carbon budget, meaning that other GHG emitting activities would have to be restricted more severely.

23.2. If such a field were developed, it is reasonable to assume that it would not start producing gas until about 2035. Extremely steep reductions in emissions will be necessary well before this date to meet the goal of net-

[9] CO_2-eq refers to the combined GHG warming effect of all gases emitted from production to burning, re-expressed as the equivalent concentration of CO_2

[10] Marquard, Andrew, et al (2023) Exploring net zero pathways for South Africa - An input study. University of Cape Town. Report. http://doi.org/10.25375/uct.22169150.v2

[11] Tcf = trillion cubic feet of gas

22 MN

zero emissions by 2050, meaning that it is extremely unlikely that the field could operate and be consistent with South Africa's 2050 net-zero commitment.

24. It is virtually certain that the world will overshoot 1.5 °C within the next few years and enter a zone of very significant risk. Current implemented and planned emissions reduction policies from countries will result in an overshoot of 2.0 °C, most likely to between 2.1 and 2.5 °C[12], increasing the severity of impacts and the likelihood of tipping points being reached. Widespread failure to implement currently planned emissions reductions, such as those articulated in South Africa's updated Nationally Determined Contribution, could well result in overshoots higher than 2.5 °C.

Natural gas, methane, CO_2 and GHG warming

25. Methane is the main component of natural gas found underground (i.e. the gas which Total is exploring for). The amount of methane in raw natural gas varies, but is typically between 70% and 97%, and on average around 95%. The second most abundant gas in raw natural gas is ethane, which is also a GHG. Natural gas affects climate through two pathways: (i) during its production and transport so called fugitive emissions arise from releases methane, ethane and other gases directly into the atmosphere (e.g., from leakages in pipelines); and (ii) during combustion, CO_2 is produced, in a similar manner to burning of oil and coal.

[12] https://climateactiontracker.org/global/cat-thermometer (accessed 09 October 2024).

26. Methane (from fugitive emissions and other sources such as agriculture) is a powerful GHG. Although it breaks down in the atmosphere faster than CO_2, its Global Warming Potential ("GWP") is ~80 times greater than that of CO_2 when measured over a 20 year period, and ~28 times greater when measured over a 100 year period[13].

27. The magnitude of natural gas production on GHG warming depends strongly on the level of fugitive emissions (gas that escape into the atmosphere during production and transport and is therefore not burnt for energy production). At zero fugitive emissions, production natural gas for electricity results in emissions of ~258 g CO_2-eq/kWh_{el}[14] while 10% fugitive emissions increase the GHG forcing to ~1439 g CO_2-eq/kWh_{el}. Actual fugitive emissions across different natural gas production systems typically fall towards the upper level of this range. In many cases, the net GHG effect of natural gas use is greater than that of oil or coal, because of these fugitive emissions.

28. Therefore, the argument that natural gas is a lower impact "transition fuel" that should be exploited in place of oil and gas is untrue in most gas production cases to date.

[13] Global warming potential (GWP) is a measure of a molecule of a given GHG's warming power, relative to a molecule of CO_2, over a given time period, typically 20, 50 or 100 years. GWP is a function of both a molecule's instantaneous warming power and its lifetime in the atmosphere.

[14] As noted earlier, CO_2-eq refers to the combined GHG warming effect of all gases emitted from production to burning, re-expressed as the equivalent concentration of CO_2, while kWh_e refers to electricity energy produced.

Proven oil and gas reserves far exceed what can be combusted

29. Together with Dr Lawrence Meckel, I have also prepared the report attached to this affidavit, marked '**MN3**', and confirm that to the best of my knowledge and belief the contents of that report are true and correct.

30. This report provides a methodology to transparently estimate national or sub-national hydrocarbon volumes that might possibly be produced by a series of commercially-viable projects in the future and the associated greenhouse gas (GHG) emissions from those projects. We also recommend a rigorous project-based classification and reporting framework that ensures these factors are considered, assessed and quantified across the life cycle of specific projects.

31. The key messages from this report are as follows:

    31.1. Estimation of yet to be discovered, commercially viable, oil and gas reserves for South Africa are possible, using well established methodologies. These estimates carry large uncertainties, but can usefully be applied to determine likely upper and lower limits for these resources.

    31.2. Well established emission factors, which determine the CO_2-equivalent greenhouse gas emissions from use of oil and gas for different purposes, can be used to calculate the emissions that would be emitted from exploitation and use of yet to be discovered oil and gas reserves

    31.3. Such information on GHG emissions from exploitation of future, yet to discovered, oil and gas reserves in South Africa can (and should) be used in support of development of the country's Nationally Determined

Contribution for reducing greenhouse gas emissions, as required by the Paris Agreement of the UNFCCC.

31.4. The South African government should develop a system, using the methods described in this report, to estimate the CO_2-eq emissions from its national yet to be discovered reserves.

31.5. The South African government could include a requirement for oil/gas exploration and producing companies to provide reserve estimates and associated emissions as part of any exploration licensing process.

PROFILE

Mark New has thirty years' experience in climate research, teaching and public outreach, thirteen of which were as director of the African Climate and Development Initiative, a cross-faculty interdisciplinary research institute at UCT. He is also Director of the ARUA (African Research Universities Alliance) Centre of Excellence for Climate and Development, in which UCT partners with the University of Ghana and Nairobi University, to drive pan-African research and teaching on climate change in Africa. Mark is internationally recognised as a leading researcher in climate change detection, attribution, impacts and adaptation. He is a recipient of the 2023 Frontiers Planet Prize, which recognises research the offers solutions to planetary environmental challenges and the 2020 Piers Sellers Prize for exceptional climate change research. He has served on several international bodies, most recently as a member of the World Adaptation Science Programme Scientific Committee, as Coordinating Lead Author for the IPCC 6th Assessment Report, and as a member of the World Climate Research Programme Working Group on Event Attribution.

RELEVANT EXPERTISE

- Climate change detection, attribution, impacts and adaptation research.
- Research project management on over 20 research grants since 2010.
- Strategic planning, large-institute management, interdisciplinary leadership and practice
- Systematic reviews, including as a senior author of GAMI (Global Adaptation Mapping Initiative)
- Leading science-policy assessments, including IPCC AR6, WGII, Chapter 17 coordinating lead author
- Adaptation tracking, including the TSITICA project mapping of adaptation projects in RSA, Kenya, Ghana
- Policy-oriented research, such as development of South Africa's adaptation research agenda prioritisation

EDUCATION AND QUALIFICATIONS

10/1993 – 09/1996: PhD, Geography, Cambridge University, UK (graduated 1999).
09/1991 – 07/1992: MPhil, Environment and Development, Cambridge University, UK (graduated 1992).
02/1987 – 11/1987: BSc Hons, Geology, University of Cape Town, RSA, (graduated 1987).
02/1984 – 11/1986: BSc, University of Cape Town, RSA (graduated 1986).

EMPLOYMENT AND EXPERIENCE

07/2023 – present: Professor, Department of Environmental & Geographical Science, University of Cape Town
07/2011 – 06/2023: Professor & Director, African Climate and Development Initiative, University of Cape Town
09/1999 – 07/2011: Lecturer / Professor in Climate Science, School of Geography & Environment, Oxford University
04/1996 – 09/1999: Senior Research Associate, Climatic Research Unit, University of East Anglia
02/1988 – 03/1991: Exploration Geologist, Southern Oil Exploration Corp., Cape Town

Evidence that current proven reserves of oil and gas exceed CO_2 budgets consistent with the Paris Agreement temperature targets

Mark New
African Climate and Development Initiative (ACDI), University of Cape Town
07 March 2022

Summary

1. The Paris agreement of the UN Framework Convention on Climate Change, to which South Africa is a signatory, has the goal of keeping human-induced global warming to well below 2.0°C, ideally below 1.5°C.

2. While the net emissions that are consistent with the Paris targets have considerable uncertainties due to biogeochemical and geophysical uncertainties about the earth system, *net* emissions from 2025 onward need to be below 250 Gt CO_2-eq to have a 50% likelihood of keeping below 1.5°C, and 550 Gt CO_2-eq to keep "well below" 2.0°C.

3. Future emissions from fossil fuels that exceed these 250 and 550 Gt CO_2-eq remaining emissions budgets will require substantial carbon dioxide removal (CDR) to meet the Paris temperature targets. Questions remain as to the viability of large-scale CDR, especially in the 25 years from now to 2050 when net zero emissions are required

4. The CO_2-eq budgets for oil and gas within any overall emissions budget vary depending on assumptions on the future mix of coal, oil and gas. The least-precautionary estimates of budgets for oil and gas consistent with 1.5°C are 248 and 121 Gt CO_2, respectively.

5. CO_2 budgets that are consistent with keeping well below 2.0°C are 396 and 194 Gt CO_2 for oil and gas, respectively.

6. Proven reserves of oil and gas, if burned, would produce *at least* 543 and 350 Gt CO_2, respectively.

7. The emissions from burning already proven oil and gas will substantially exceed the budget available to meet the 1.5°C target, by at least 210% and 290%, respectively

8. Emissions of CO_2 from burning proven oil reserves will also substantially exceed the "well below 2.0°C" oil and gas emissions budgets, by at least 137% and 194%, respectively.

Background context: the Paris agreement

The "Paris Agreement" is a legally binding international treaty on climate change, adopted by 196 Parties to the UNFCCC at COP 21 in Paris, on 12 December 2015 and entered into

2.2 MN

force on 4 November 2016[1]. South Africa is a signatory to the Paris Agreement. One of the goals of the agreement is to limit global warming to well below 2.0 degrees Celsius, preferably to 1.5 degrees, compared to pre-industrial levels.

This report assesses whether proven global reserves of oil and gas – if burned – would lead to greenhouse emissions that cause warming in excess of the Paris Agreement global temperature targets.

Greenhouse gas emissions budgets to meet the 1.5°C and 2.0°C targets

The 2018 IPCC Special Report on 1.5 Degrees (SR15)[2] specifically assessed the greenhouse gas emission reduction pathways that will keep global warming below the Paris Agreement 1.5°C and 2.0°C targets. The SR15 assessment was updated in the 2022 Working Group III report of the IPCC Sixth Assessment[3].

There are a range of possible future emission pathways that meet these targets, but as a rule, the sooner global emissions peak, the less severe are the required post-peak reductions needed to meet these temperature targets. Pathways that peak late and decline slowly will either cause greater warming, possible overshooting 2.0°C, or will need carbon dioxide removal to reduce GHG concentrations to levels consistent with the 1.5°C and 2.0°C targets.

Uncertainties in carbon cycle feedbacks and climate sensitivity mean that any emissions pathway could lead to a range of possible future warming levels. Therefore, scientific literature often presents a likelihood of a particular emissions pathway meeting a given target (e.g. 50%, 66%, 90%). A higher likelihood threshold (a more precautionary approach) will reduce the allowable future emissions.

A common approach to summarising the emissions reduction challenge is to estimate a remaining CO_2 budget (the cumulative total of emissions into the future) that meets the 1.5 or 2.0°C target[4]. In 2018, the IPCC estimated that budget to be 580 Gt CO_2 to have a 50% likelihood of keeping below 1.5°C, and 420 Gt CO_2 for a 66% likelihood[4]. The budget for keeping below 2.0°C was 1500 and 1170 GtCO_2 for 50% and 66% likelihoods, respectively. Given global emissions of CO_2 since 2018 have been approximately 200Gt (2019-2024, 40Gt per year), the current remaining budget for 1.5 degrees can be adjusted down to 380 Gt CO_2 and 220 Gt CO_2 (50% and 66% likelihood) and similarly, the 2.0 degrees budget to

2362

1300 and 970 Gt CO_2. Different estimates of this budget are shown in Table 1. The latest IEA world energy outlook report adopts a budget of 500Gt for 1.5°C, based on similar logic[5].

How a future CO_2 budget could be distributed between different sources (coal, oil, gas, others) depends on the mix of these sources into the future. Table 1 presents estimates of the total CO_2 budget consistent with 1.5°C and 2.0°C from the IPCC SR15 (which itself summarises underlying literature), along with a breakdown of fossil fuel components of that budget between coal, oil and gas, under different emissions reduction scenarios in line with 1.5°C. Although IPCC does not provide a breakdown for other temperature targets, we estimate the budgets by scaling the 1.5°C budgets for the other warming targets. All scenarios assume that coal phases out more quickly than gas and oil, and the higher budgets assume significant carbon dioxide removal (CDR; see Box 1). In addition, scenarios with higher oil budgets are offset by lower gas budgets and vice versa. For oil and gas, the remaining *maximum* 1.5°C budgets (assuming these two energy sources are preferred to coal, and 50% likelihood) for each that do not depend on large-scale CDR are 248 and 121 Gt CO_2 respectively. The combined maximum budget across scenarios is 369 and 468 Gt CO_2, assuming minor and significant CDR, respectively.

If one adopts the recommendation of Matthews et al[6] that the Paris target of "well below" 2.0°C equates to 1.75°C, with a likelihood of 66%, the maximum budgets for oil and gas scale to 396 and 194 Gt CO2, without significant CDR.

*Table 1. Remaining emissions of CO_2 consistent with a 1.5 and 2.0°C warming targets, from the IPCC SR15, adjusted to take account of the 200Gt CO_2 emitted up to 2024. Net emissions represent the difference between emissions and CDR. The IPCC P1-P4 scenarios show total actual emissions that deliver the net emission target, with increasing levels of CDR from P1 to P4. *Note that emissions breakdown for P1-P4 for 2.0°C and 1.75°C are estimates arrived at by scaling 1.5°C estimates by the net emissions estimate.*

	Current Emissions (1)	Emission Budget for Temperature Target / Likelihood of Meeting Target (Gt CO2)																	
		1.5°C/50%				1.5°C/66%		1.75°C/50%				1.75°C/66%		2.0°C/50%				2.0°C/66%

Box 1: Carbon-dioxide removal as a climate mitigation option

Carbon-dioxide removal (CDR) refers to the "process of removing CO_2 from the atmosphere" so as to achieve "negative emissions"[8,9]. There are two broad categories of CDR, natural and artificial. Examples of natural CDR include afforestation and land restoration, where plants (especially trees) are used to take up CO_2 via photosynthesis and this is then stored in living plant mass and later as dead material on and within the soil. Artificial methods, called "direct air capture and carbon storage" (DACCS), use mostly yet to be proven engineered processes to capture atmospheric CO_2 for subsequent geological storage. A hybrid approach called "bioenergy with carbon capture and storage" (BECCS) utilises biomass for energy, capturing the CO_2 emissions and similarly to DACCS, storing them geologically. Land-based approaches such as afforestation and BECCS frequently will involve trade-offs with use of land for other purposes, especially food production, and their feasibility depends strongly on transformations in the global food system towards low-meat diets. The storage of CO_2 in BECCS and DACCS require substantial geological storage sites, and these are not always close enough to where the CO_2 is captured, for example at a power plant. Overall, (i) some CDR methods have been shown to be feasible, but there are doubts as to whether they can be deployed at scale without major negative side-effects; (ii) the remaining CDR methods are yet to be proven; (iii) nearly all CDR methods are expensive, at much greater than US$ 100 per tonne of CO_2, adding considerably to the full cost of burning fossil fuels.

Proven reserves of coal, oil and gas, and their combustion CO_2 emissions

Estimates of proven fossil fuel reserves vary widely between studies, due to different definitions of what constitutes proven, how such reserves are estimated, whether conventional or unconventional sources are considered, and which geographic regions are included (e.g., OPEC versus non-OPEC; Arctic included or excluded)[10]. Table 2 shows a range of estimates from different sources, summarised by McGlade and Ekins[10] and as well as other sources. The upper and lower ranges from these studies are 1,300-2,300 billion barrels of oil, 186-2,200 trillion cubic metres of gas, and 850-1,069 billion tons of coal, respectively.

The combustion emissions of CO_2 from different fossil fuel sources is dependent on several factors, including the characteristics of the raw resource (e.g., heavy versus light crude oil), the refining process and end product (e.g. gasoline versus diesel), and the efficiency of the eventual burning for energy. Estimates of future CO_2 emissions from fossil fuels are therefore dependent on assumptions about how these fuels are used. The most conservative estimates from the literature suggest that the *minimum* emissions from

combustion of already discovered oil, gas and coal will be 543, 350 and 1,540 Gt CO_2 respectively (bold text in Table 2). If the reserves or emissions per unit fossil fuel are higher, then these values increase.

Table 2. Estimates of known global reserves of oil, gas and coal, and associated estimated emissions of CO_2 from their combustion (emission factors from McGlade and Ekins[4]). Gb = billions of barrels; Tcm = trillion cubic metres; Gt = billions tonnes.

Source	Oil (Gb)	Oil-CO_2 (Gt)	Gas (Tcm)	Gas-CO_2 (Gt)	Coal (Gt)	Coal-CO_2 (Gt)

BP (2020)	1,734	644*	199	376*	1,068	2,379*

BGR = Federal Institute for Geosciences and Natural Resources[11]; IEA = International Energy Agency[12]; GEA, Global Energy Assessment[13]; ME = McGlade and Ekins[10]; HO = Heede & Oreskes[14] using reserve data obtained from BP (2014)[15]; BP = Authors' own calculations for emissions based on reserve data from BP (2020)[16] using the methodology reported in Heede & Oreskes[14].

Comparison of Paris CO_2 budgets and emissions from proven reserves

Based on the IPCC estimates of oil and gas CO_2 emissions budgets consistent with the more ambitious 1.5°C Paris Agreement target, the least precautionary (maximum) budget (50% likelihood of meeting target) requires net CO_2 emissions of 380 Gt in total, and around 189 and 92 Gt for oil and gas, respectively. This compares to emissions from burning of the lowest estimates of proven oil and gas of 543 and 350 Gt CO_2, respectively. Therefore, there is already sufficient proven oil to supply nearly triple the emissions consistent with 1.5°C, while for gas, proven reserves are nearly over three times the 1.5°C CO_2 budget.

ZR MN

2365

These broad figures are consistent with a similar analysis undertaken by Welsby et al (2021)[7] who estimate that nearly 60 per cent of oil and methane, and 90 per cent of coal must remain unextracted to keep within a 1.5 °C carbon budget, with a 50% likelihood.

Emissions budgets are more generous for the 2.0°C target. The least precautionary budget (2.0°C at 50% likelihood) allows for net emissions of 1300 Gt CO_2, of which oil and gas could make up 403-659 and 272-323 Gt (without significant CDR). However, many have argued that the Paris objective of keeping "well below 2.0°C" would require a more precautionary approach in setting these budgets, for example by choosing a 66% likelihood of keeping below 1.75°C[6]. In this case, the net emissions budget is 680 Gt CO_2 in total, of which oil comprises 297 Gt CO_2 and gas 146 Gt CO_2 (without significant CDR). Therefore, emissions of 543 and 350 Gt CO2 from burning proven oil and gas reserves would thus result in significantly exceeding this "well below 2 0°C" carbon budget for both oil and gas. It is only in the case of the least precautionary emissions scenarios, with a high risk of overshooting 2.0°C, that emissions from oil and gas are less than those from proven reserves.

METHODOLOGY FOR ESTIMATING POSSIBLE PRODUCIBLE HYDROCARBON VOLUMES AS A BASIS FOR DETERMINING POTENTIAL GREENHOUSE GAS EMISSIONS FROM FUTURE COMMERCIAL OIL AND GAS DEVELOPMENTS

Dr. Lawrence Meckel (Monteverde Energy, Australia) &
Dr. Mark New (The University of Cape Town, South Africa)

October 2024

Summary

This report provides a methodology to transparently estimate hydrocarbon volumes that might possibly be produced by a series of commercially-viable projects in the future and the associated greenhouse gas (GHG) emissions from those projects. We also recommend a rigorous project-based classification and reporting framework that ensures these factors are considered, assessed and quantified across the life cycle of specific projects. The authors' contributions are based on their respective professional experiences with international petroleum and service companies, including reporting to several jurisdictional standards regarding opportunity and portfolio producible volume estimation.

Key messages

1. Information on GHG emissions from exploitation of future, yet to discovered, oil and gas reserves in South Africa can (and should) be used in support of development of the country's Nationally Determined Contribution for reducing greenhouse gas emissions, as required by the Paris Agreement of the UNFCCC.
2. Estimation of yet to be discovered, commercially viable, oil and gas reserves for South Africa are possible, using well established methodologies. These estimates carry large uncertainties, but can usefully be applied to determine likely upper and lower limits for these resources.
3. Well established emission factors, which determine the CO_2-equivalent greenhouse gas emissions from use of oil and gas for different purposes, can be used to calculate the emissions that would be emitted from exploitation and use of yet to be discovered oil and gas reserves.
4. The South African government should develop a system, using the methods described in this report, to estimate the CO_2-eq emissions from its national yet to be discovered reserves.
5. The South African government could include a requirement for oil/gas exploration and producing companies to provide reserve estimates and associated emissions as part of any exploration licensing process.

Introduction

In 2022, oil, gas, and flaring accounted for 54% of global emissions and 66% of African emissions, but only 15% in South Africa, where effectively no oil and gas is currently produced (emissions are from imported oil and gas).[1] However, the petroleum industry has growth aspirations[2] which could change the percentage of emissions in South Africa, and which should be adequately planned for.

2 of MN

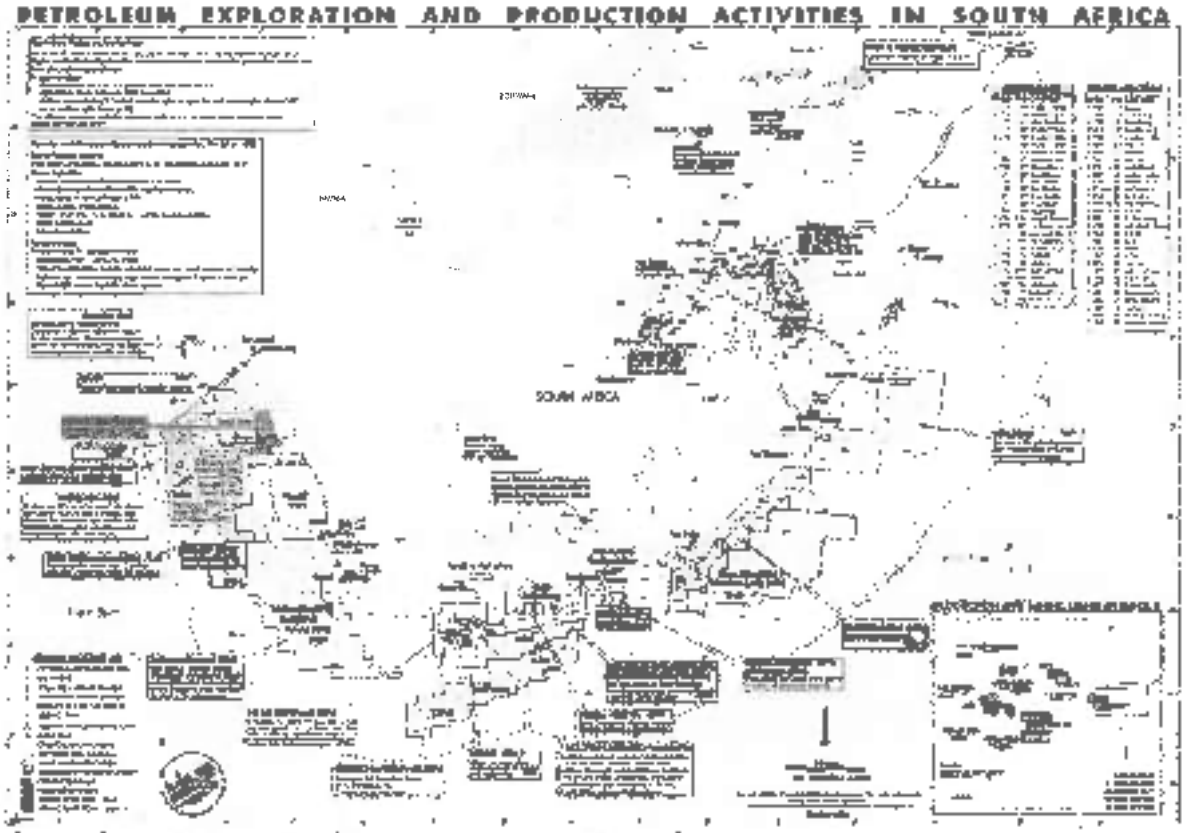

Figure 1. Petroleum exploration and production activities in South Africa.[3]

Given the lack of petroleum projects and the relative immaturity of the petroleum market in the South Africa, the Government is well positioned to develop (i) an *a priori* understanding of how much oil and gas might be expected to be produced in the future; (ii) an estimate of the expected quantity of Scope 1, Scope 2, and Scope 3 GHG emissions associated with that oil and gas production; and (iii) plans, policies, regulations, and laws to address these as-yet unquantified emissions in short- and long-term scenarios.

The reasons for the South African government to perform a quantified and transparent assessment of expected volumes of produced hydrocarbons and associated GHG emissions are as follows:

- To manage its resources effectively and sustainably, including to provide due diligence on companies' statements and reports;
- To develop coherent, holistic national policies, as part of a broad duty of care to the general public;
- To communicate the basis for these policies to all stakeholders;
- To estimate resource-related emissions adequately and realistically, in consideration of what is required to meet Nationally-Determined Contributions and "fair share" contributions to reducing global emissions (for which governments are expected to provide some justification of their proposed efforts); and
- To plan and budget future potential tax revenue effectively.

Similarly, the government has the opportunity to require companies operating in South Africa to report to a standard that facilitates the above criteria. If implemented, recoverable quantities associated with companies' projects would be described and categorized in a "manner that is consistent with scientific and socialeconomic information describing the economy as well as with the information describing the projects to recover them,"[4] consistent with industry Best Practice.

Methodology

A generally accepted Best Practice workflow for estimating petroleum resources and associated GHG emissions that could be applied at country or basin level in South Africa is as follows:

1. Establish a probabilistic range of Yet-to-Find (YTF) estimate of, technically-recoverable conventional and unconventional oil and gas resources, including a consideration of the chance of making a technically-recoverable discovery[5].
2. Multiply YTF by a reasonable range of Chance of Commercial Success (COCS) factors to generate a stochastic distribution of expected volumes at country level
3. Calculate the associated GHG emissions with the stochastically calculated range of oil and gas volumes using agreed emissions factors (either nationally or internationally defined).
4. Introduce a classification and reporting framework for resources and reserves that provides more granularity at the level of individual projects by explicitly considering environmental, social and economic viability; technical feasibility and maturity; and degree of confidence in estimates of the potential recoverability of the quantities.[6]

Yet-to-Find

YTF is an estimate of the remaining technically-recoverable hydrocarbons to be discovered in a petroleum province (typically a basin, assessment area, or country). Within the province, conventional and unconventional oil, gas, and natural gas liquids (NGL) resource estimates are typically reported separately, each as a ranges of possible outcomes, based on expert assessment of the associated geology. The range is presented as discrete volumetric values of low, mid, and high estimates of oil, gas, and NGL resources.

- "Low" is generally taken at the 95th, 90th, or 85th percentile, meaning that the reported YTF estimate is expected to exceed that value in 95%, 90%, or 85% of successful outcomes.
- "Mid" is generally taken at the 50th percentile, meaning that the reported YTF estimate is expected to exceed that value in 50% of successful outcomes.
- "High" is generally taken at the 5th, 10th, or 15th percentile, meaning that the reported YTF estimate is expected to exceed that value in 5%, 10%, or 15% of successful outcomes.

Estimates may be made by governmental organizations to help plan long term energy policy, by consulting firms to provide commercial advice to clients in industry, finance, insurance, among others; by E&P companies to make proprietary portfolio decisions; and by other researchers for various reasons.

Methodologies for calculating YTF are long-established in the industry.

Halliburton and Schlumberger, the two largest oilfield services companies in the world, describe best practices, commonly-used methodologies, and their associated uncertainties [7,8]

- The **Areal Productivity** or **Areal Yield** method applies a bulk volume of oil, gas, and/or NGL that has been produced from a unit area in a well understood and suitably analogous province to the area being considered. For instance, if the area of interest "X", which has an area of 1000 km², is considered analogous to well-explored Area "Y", which has produced an average of 1 million barrels of oil per square kilometer, then the amount of petroleum that might be produced from Area "X" could be estimated as 1 billion barrels of oil (=1000 km² multiplied by 1000000 barrels of oil per square kilometer). Typically, a range of appropriate analogues is considered.
- The **Source Rock Yield** method "is mostly used in underexplored, frontier basins and is derived by calculating the volume of hydrocarbons likely generated and expelled from source rocks. This value is modified by estimating the losses that may have occurred [...], and the likely recovery factor [.]. An estimate for the YTF is derived once the volume of discovered recoverable hydrocarbons is subtracted from this value" (Simmons et al., 2021).

---

[5] The chance of making a technically-recoverable discovery is typically referred to as the Geological Chance of Success (GCOS) or Geological Probability of Success (GCOS), expressed as a percentage, based on the state of knowledge about the presence and quality of relevant elements of the petroleum systems (charge & migration, reservoir, trap, seal).

22 MN

- **The Creaming Curve, ZIPF and Field Size Distribution** methods are only useful in provinces where a reasonably large number of discoveries has already been made, so are inappropriate for South Africa.
- **The Summing Prospect Inventory method** is relatively straightforward, provided the prospect inventory is sufficiently comprehensive. Each prospect will typically have low, medium, and high volumetric estimates and a Geological Probability of Success, which can be multiplied together and summed to get a total estimate. Although such an inventory does not currently exist for South Africa, there is no reason such an inventory could not be required to be provided by the operator of each lease.
- **The Feature Count Stochastic Prediction** method is based on probabilistically estimating the number of future discoveries based on three parameters. These are
    - The size range of existing discoveries or mapped prospects;
    - The chance of success — This is generally estimated as the number of discoveries in a play, divided by the number of wells targeted at a play. Chance of success improves with time as a play becomes better understood.
    - The number of prospects remaining to be drilled — This element is the hardest to estimate, as many prospects do not meet risk, volume, or economic thresholds and are unlikely to be drilled

Alan Fourn, a well-respected industry scientist with 35 years of experience, provides a synopsis for non-specialists of these techniques for estimating YTF.[5]

Table 1: Advantages and disadvantages of commonly used methods to calculate Yet-to-Find resources (Fourn, 2018)

Yet to find estimation method	Geological input	Ease of method	Limitations
Analogue field	Minimal	Easy and quick to do	Is it really an analogue? - limited scope for sensitivities – use only as a sense check
Source Rock Yield	High	Can be easy – spreadsheet or more complex - basin model	Need some data on the source rocks in the basin or make assumptions – can run multiple sensitivities - Number calibration in estimating migration losses and assigning charge volumes to different plays – BUT makes geologists think about what could be possible
Creaming Curves	Low	Easy and quick to do	Extrapolates from known plays only – how reliable is the resource volumes data? – using rear view mirror – cannot account for any new advances in technology or ideas – but can be a sense check
Zipf and Field Size Distribution plots	Low	Easy and quick to do	Are the fields really missing? – is the economic threshold applied? Are we missing plays? Is the field size distribution following Zipf's Law? - Avoid
Summing Prospect Inventory (as used by UKOGA)	High	Need to have a risked resource number for every prospect	Need to evaluate how likely is a prospect to be really drilled. Reliant on vaguely accurate estimates of prospect resource size and COS – are these overestimated? Need to apply thresholds. What about unmapped areas or plays?
Feature Count Stochastic Prediction (as used by USGS in World Petroleum Assessment)	Moderate	Easy to do, but need appropriate software	Where is the origin of the inputs? – can be a bit like the Drake Equation (SETI) – need to apply cut offs for economics. Very difficult to effectively run for new plays. – BUT can run many realisations and can run a "what would it take?" exercise

Numerous factors should be considered in YTF estimates, including:

- Analyses should be performed or audited by a competent independent expert
- Data, assumptions, and methodology should be transparent
- Any analogues considered should be checked for appropriateness and completeness
- Uncertainties, risks, and dependencies should be described and quantified
- Volumes should be presented as a range (Low/Mid-High)
- Reported volumes should be risked in terms of the likelihood of success
- Volume distributions should include a minimum field size threshold

[5] Fourn, A. (2018). Estimating Yet to Find in Petroleum Exploration. Available at: https://www.linkedin.com/pulse/estimating-yet-find-petroleum-exploration-alan-fourn/.

22 MN

2370

Given the wide range of uncertainty in many of the input parameters, YTF estimates can vary widely (sometimes by orders of magnitude), depending on who does the analyses, and the assumptions, data, and analogues used. However, YTF estimates are considered sufficiently accurate to be useful for establishing broad expectations of future potential.

Even so, not all technically-recoverable volumes will eventually be determined to be commercially-viable to produce. As such, the actual volume of produced petroleum is expected to be less than the YTF, as a function of the Chance of Commercial Success.

Several 'Feature Count Stochastic Predictions' of YTF in South Africa are available from the United States Geological Survey (USGS) and US Energy Information Administration (EIA).[10,11,12,13,14] Commercial consultancies also provide estimates that are available to be purchased.[15]

Alternatively, the government of South Africa could compile independent volumetric ranges, chances of technical success, and other parameters from an inventory of Leads, Prospects, and Play Analysis, such as that implemented by the UK North Sea Transition Authority (NSTA, previously Oil & Gas Authority, OGA).[16]

Chance of Commercial Success

COCS is a risk-based representation of the likelihood that a specified volume of technically-recoverable hydrocarbons will be produced at a future point in time. All discovered volumes will not necessarily be produced, for any number of reasons, including:

- Unfavorable global or local commodity or contract prices
- Low-ranking value (e.g., Net Present Value) of a given project relative to other projects in portfolio
- Lack of infrastructure
- Cost of capital
- Lack of social 'license to operate'
- Lack of environmental or other regulatory approvals
- Corporate decarbonization targets or goals

The ratio of commercial success to technical success is the chance of commercial success (in the figure below, COCS = POSc/POSg). As a rule of thumb, slightly more than half of all technically successful discoveries in representative petroleum basins are potentially commercial (~65% for oil; ~60% for gas, with some scatter).[17,18] Other discoveries are too small to be developed (or are 'stranded' from a commercial perspective).

The impact of commerciality is recognized in common classification frameworks such as the widely-used Petroleum Resource Management System (PRMS), which differentiates volumes as Prospective Resources (undiscovered), Contingent Resources (discovered, but sub-commercial), Reserves (commercial), and Production (sold hydrocarbons that emit GHGs) on the basis of the chance of commerciality.

Estimating the Range of Likely Produced Petroleum Volumes Given Uncertainties

Monte Carlo simulation is a robust method of estimation in which a series of significant input variables (x_1, x_2, x_3, ..., x_n) is randomly sampled in a statistically-meaningful number of trials to determine the resulting range of probable outcomes (y_n). In the simplistic case proposed here, a range of technically-recoverable petroleum volumes (YTF) would constitute input variable x_1, while a range of realistic chances of commercial success (COCS) would constitute input variable x_2. Multiplying a randomly selected single value of x_1 by a randomly selected single value of x_2 will generate a single outcome y_1 and doing this a predetermined number of times will provide the probabilistic range, y_n

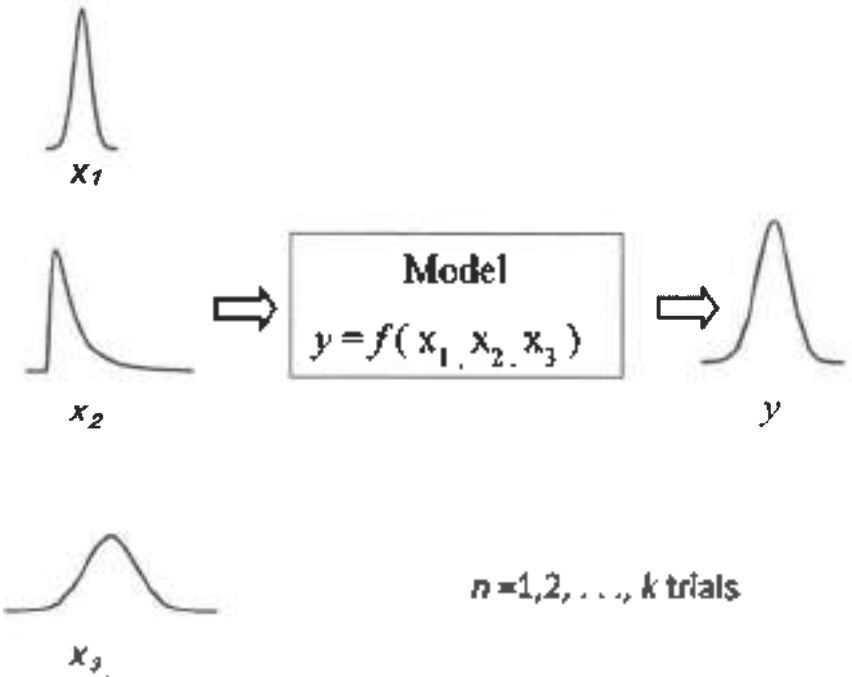

Figure 1. Generic example of stochastic combination of three input variables (x_1, x_2, x_3) to generate a distribution of outcomes (y) after a series of "k" trials [2]

As an example, if the YTF range were estimated at 826-3850 million barrels of oil (MMBO) and the COCS were estimated at 35-70%, then a random sampling of five equally-likely outcomes of each input variable might result in a range of petroleum volumes that are likely to be commercially viable of 400-2275 MMBO.

Trial #	826 MMBO < YTF < 3850 MMBO	35% < COCS < 70%	YTF*COCS
1	1000 MMBO	40%	400 MMBO
2	3500 MMBO	65%	2275 MMBO
3	2000 MMBO	60%	1200 MMBO
4	3000 MMBO	45%	1350 MMBO
5	2500 MMBO	50%	1250 MMBO

In practice, a much larger number of samples would need to be considered in order to be statistically meaningful. Additional input variables (risks) could also be considered in a more complex model. One such variable might be Chance of Regulatory Approval.

Greenhouse Gas Emissions

The greenhouse gas emissions from any oil or gas production can be calculated relatively easily, although there are a range of factors that influence these emissions, all of which have some uncertainty. To estimate such emissions, we need to use a formula, known as the emissions factor (EF), which calculates emissions as a function of the type of

[2] Benke, K., Norng, S., Robinson, N, Benke, L., & Peterson, T. (2015). Error propagation in computer models: analytic approaches, advantages, disadvantages and constraints. Stoch Environ Res Risk Assess 32, pp. 2971–2985

fossil fuel (oil, gas, coal), how the fuel is produced, and the way that the fossil fuel is used (such as for electricity generation, combustion in engines for transport, mineral beneficiation, and fertilizer production).

For ease of comparison, emissions of different gases are usually described in CO_2-eq, the effect of a given gas over 100 years compared to the effect of CO_2, the most abundant fossil fuel gas. CO_2-eq depends on two factors: the relative warming strength of a gas and how long it lasts in the atmosphere after being emitted. A gas with high GH warming strength that lasts longer in the atmosphere after being emitted has a higher CO_2-eq. For example, methane, which is 84 times more powerful than CO_2, only lasts about 20 years in the atmosphere, so has a CO_2-eq of 25.

For energy production, emissions come from two main sources: production and consumption (burning). During consumption, a given fuel, such as natural gas is burned, and CO_2 is the main gas emitted. During production, emissions are associated with the energy used in production, flaring at production sites, and fugitive emissions (leakages) during production and transport. Fugitive emissions can be a big proportion of total CO_2-eq of natural gas and oil production, because they occur as raw natural gas, with high CO_2-eq values.

Emission factors take into account the above production and use variations. For example, the average CO_2-eq for natural gas used to generate electricity in Europe is 0.244 kg CO_2-eq / kWh ICV (European mean) with 5% uncertainty. About 20% of this is from production and 80% is from combustion. A complication for use-related emissions calculations arises if the natural gas or oil is exported and refined and/or burned outside of its source country – that proportion used outside the country would not count for national greenhouse gas accounting under UNFCCC rules. However, companies involved in production and export should be including all downstream use in their Scope 3 emissions reporting, and may well be required to do under new laws in some jurisdictions (such as the EU and California). Apportioning emissions from gas and oil production and use into national and extra-territorial categories, and similarly into Scope 1, 2 and 3 categories for companies, is relatively simple.

To determine the likely emissions from a given commercially exploitable oil or natural resource, a median and upper/lower range can be easily calculated, for a given use, and with assumptions about the production emissions. Emissions factors used to do this can be nationally determined, or internationally available, such as those provided by the International Energy Association[21] South Africa has a comprehensive set of emissions factors for electricity production[22] but emissions factors for other uses tend are often drawn from international sources.

Examples of emissions factor ranges, and their application to estimate CO_2-eq emissions are shown in Table 2 and Table 3 below. Numbers such as these shown in Table 3 can be used in scenario planning for NDCs, to understand how YTF reserves, if exploited, affect NDC emission reduction pathways and associated policies to deliver them. One important factor for NDC considerations is that oil and gas produced and used domestically has higher CO_2-eq emissions that if it was imported, because of the production emission component of approximately 20% of total emissions.

Table 2. Example emission factors for natural gas for electricity generation and domestic heating (derived from various sources), assuming different levels of thermal (combustion) efficiency and diffuse emissions during production.

Use	Emissions Factor (tCO_2-eq / kcf)		
Thermal efficiency	High	Med	Low
Diffuse emissions	Low	Med	High
Electricity	0.048	0.086	0.147
Heating	0.033	0.059	0.117

Table 3. Illustrative range of CO_2-eq emissions from a given natural gas reserve size in Tcf (trillions of cubic feet), assuming an average EF across use for electricity and heating, and low, medium and high diffuse emissions

EF (tCO_2-eq / kcf)	0.043	0.077	0.133
Reserves of Gas (Tcf)	Emissions (Mt CO_2-eq)

Project-Level Classifying and Reporting

In order to provide a consistent, auditable trail of how estimates of YTF hydrocarbon volumes and the associated emissions mature through time, many governments implement classification and reporting frameworks that require companies to provide an external assessment by a qualified expert of the estimated petroleum volumes associated with a specific project, as well as an assessment of the environmental impact. These assessments are then updated as the project matures towards commercial viability and during production.

A robust classification system is "a fundamental element to support a common language for communicating risk and uncertainty related to petroleum projects"[23] which the government can use to ensure common reporting standards among different companies.

The *United Nations Framework Classification (UNFC) for Petroleum Resources*[24] is currently the global Best Practice framework for sustainable management of energy and mineral resources. UNFC is designed to ensure harmonized decision-making on the technical feasibility, socio-environmental concerns, and commercial potential of projects to develop resources.

UNFC is "a universal system for classifying and reporting minerals, energy, and other resources. It provides a standardized approach to ensure consistency, transparency, and sustainability in resource management. By integrating environmental, social, and economic considerations, UNFC aligns with global sustainability goals, including the 2030 Agenda for Sustainable Development and the Paris Agreement. Its comprehensive framework supports decision-making processes across various sectors, facilitating efficient and responsible resource use globally. UNFC is essential for governments, industries, and stakeholders committed to sustainable resource management,"[25] insofar as resource volume, associated GHG emissions, and other socio-environmental factors are considered holistically, rather than independently.

UNFC aims to serve the following four principal needs[26]

1. The needs in international energy and mineral studies to formulate robust and long-sighted policies.
2. The needs of governments in managing their resources accordingly, allowing market prices to be transferred to the wellhead with as little loss as possible.
3. The industries' needs for information while deploying technology, management and finance to secure energy supplies and capture value efficiently within the established frameworks to serve its host countries, shareholders and stakeholders.
4. The financial community's need for information to allocate capital appropriately, providing reduced costs and improved long-sightedness through the application of lower risk-compensated discount factors.

In jurisdictions where UNFC is the regulatory reporting standard, such as the state of Queensland, Australia, the regulator is able to quantitatively review the emissions associated with a project to determine whether it meets legal standards to proceed.

Dr Lawrence Meckel

Dr. Lawrence Meckel has more than 30 years of professional experience in energy and decarbonization projects on 6 continents, working within the frameworks of governmental and regulatory authorities, joint venture partners, environmental agencies and NGOs, and local communities.

Since 2021, Dr. Meckel has been involved in renewable energy, decarbonization, and energy transition activities. As Founder of Monteverde Energy, Dr Meckel provides sustainability consultancy for public and private international companies and local governments in Australia and USA. As Commercial Director for SolMax, he is responsible for commercializing industry-leading mining technology. With multiple geothermal start-ups, he has built portfolios of renewable energy assets. As Storage Program Manager for CO2CRC, he led technical services and R&D projects supporting international decarbonization projects. He is also a Tutor and energy industry SME for the University of Cambridge Institute for Sustainability Leadership.

From 1997-2021, Dr. Meckel worked in oil and gas, including senior leadership positions since 2008. He began his career with Shell and Woodside, where he developed high-level expertise across energy exploration and production and R&D, focused on developing and applying advanced technologies to provide science-based resource assessments. From 2016-2021, he was VP of Global Exploration and a member of the Risk Management Committee for Latin America's largest private E&P company

Dr Meckel holds a PhD from ETH-Zürich (Swiss Federal Institute of Technology), an MA in Geology from the University of Texas at Austin (USA) , and a BA with honours in Geology from Williams College (USA).

Dr Mark New

Mark New is a climate scientist with 30 years of research experience in climate change, including estimating the impacts of different future greenhouse gas emissions on global and regional climate. He holds a PhD in climate science from University of Cambridge, an MPhil in Environment and Development, also from Cambridge University, and a BSc in Geology from the University of Cape Town.

From 2011 to 2023 he was director of the African Climate and Development Initiative, a cross-faculty interdisciplinary research institute at the University of Cape Town. He is also Director of the ARUA (African Research Universities Alliance) Centre of Excellence for Climate and Development, in which UCT partners with the University of Ghana and Nairobi University, to drive pan-African research and teaching on climate change in Africa. Mark is internationally recognised as a leading researcher in climate change detection, attribution, impacts and adaptation.

He is a recipient of the 2023 Frontiers Planet Prize, which recognises research the offers solutions to planetary environmental challenges and the 2020 Piers Sellers Prize for exceptional climate change research. He has served on several international bodies, most recently as a member of the World Adaptation Science Programme Scientific Committee, as Coordinating Lead Author for the IPCC 6th Assessment Report, and as a member of the World Climate Research Programme Working Group on Event Attribution.

EXPERT AFFIDAVIT: JEAN HARRIS

I, the undersigned,

JEAN MARY HARRIS

do hereby make oath and say:

1. I am an adult female marine scientist, and am currently the Executive Director of WILDOCEANS, the marine programme of the Wildlands Conservation Trust

AN

(WILDTRUST), and NGO focused on biodiversity protection and building socio-ecological resilience in the Southern Africa and western Indian Ocean.

2. The facts contained in this affidavit fall within my personal knowledge, except where I indicate otherwise and are, to the best of my knowledge, true and correct. To the extent that I rely on information supplied by others, I believe that such information is true and correct.

3. Together with Dr Jennifer Olbers and Dr Kendyl Wright, I have prepared the report annexed hereto marked "JH1".

4. My qualifications and experience are set out in a copy of my *curriculum vitae*, attached to this affidavit marked "JH2". I respectfully submit that I am qualified by my qualifications, training and experience to express the expert opinions which are set out in the report referred to above.

5. I further confirm that the report is to the best of my knowledge and belief true and correct.

JEAN MARY HARRIS

I hereby certify that on the 13 day of NOVEMBER 2024 in my presence at DURBAN the Deponent signed this Affidavit and I administered the oath/affirmation in full compliance of the provisions of Act 16 of

1963 and Regulations promulgated thereunder (GN R1258 in GG 3619 of 21 July 1972, as amended).

COMMISSIONER OF OATHS

ADDITIONAL COMMENTS ON THE TGS ORANGE BASIN BASIC ASSESSMENT REPORT FOR RECONNAISSANCE, LOCATED OFFSHORE THE WEST COAST, SOUTH AFRICA.

Dr JM Harris, Dr JM Olbers and Dr K Wright

10 November 2024

These comments were prepared by WILDTRUST marine scientists, namely Dr JM Harris, Dr JM Olbers and Dr K Wright, as requested by Natural Justice, and relate to an Appeal Decision of an Environmental Authorisation (EA) granted (26 April 2023; Ref: EIMS 1520). This document provides additional comments on the Basic Assessment Report (BAR), dated 6 October 2022, on the TGS Orange Basin Basic Assessment Report for reconnaissance, located offshore the west coast, South Africa.

Having reviewed the BAR and associated specialist reports, it is our opinion that the implications to marine fauna are not being sufficiently acknowledged in the EA to ease/allay fears around the impact of seismic survey (reconnaissance) activities. Comments on the ecological and biological components are given below, but by no means are comprehensive and are intended to highlight key concerns.

General impacts

Historically, the focus of seismic survey impacts and sound has been on cetaceans, with decades of effort and literature published globally to obtain a better understanding of the consequences to these animals which rely on sound for survival, including for communication using sound mainly for social interactions such as mating, mother-calf recognition, predator avoidance and locating food (see reviews of Gordon et al 2003, Weilgart 2007, Weilgart 2013, Kavanagh, 2019). Notwithstanding this, it has been well documented that various other animals also require and use sound critical to ensure functional life cycles (see Jasny et al, 2005). Sound is used by many species, by actively producing sound (Tyack 1981), by listening to sounds emitted by other living organisms (Clark et al. 2009; Van Opzeeland 2010), and taking cues from physical or non-living factors producing sounds, contributing to the ambient background noise, such as wind; waves, swell, bubbles, currents, turbulence, earthquakes, rainfall, ice cracking or breaking (Hildebrand 2005). Apart from cetaceans, many marine animals rely on producing a sound that is heard, and also having the ability to hear a sound and interpreting the sound for their survival (Hildebrand 2005).

Cetaceans

The BAR highlights that occurrences and encounters with various cetacean species are inevitable, all of which are protected in South African waters. Information supplied on cetaceans is largely based on observational data, i.e. Marine Mammal Observer (MMO) surveys (Figures 29a &b, and 30; Biodiversity and Ecosystem Services Assessment). These data are somewhat outdated and do not account for the population dynamics of the cetaceans present in the reconnaissance area or area of interest (AOI). To understand the risk of seismic surveys on cetaceans, the population status of species of concern needs to be established. This requires many years of research and depends on the temporal trends for each marine mammal species (Nowacek et al., 2015) specific to the AOI. Considering this, developing other metrics for cetacean population status, such as current distribution, ranging patterns, population structure, and body condition, should be a priority (Nowacek et al., 2015). Furthermore, without a proper understanding of the ecosystem within and surrounding the AOI, as

AV

highlighted in the BAR, it is impossible to assess the impacts of seismic noise on prey distribution, which ultimately influences the predator populations and distributions, such as with cetaceans (Nowacek et al., 2015).

Behavioural responses to noise are dependent on various factors, such as age, sex, presence of offspring, location and an individual animals' previous encounter with a specific sound or noise. Behavioural responses may include modification of vocal behaviour, displacement from important habitats, and other subtle responses, including increased breathing rates, change in dive duration, time spent at the surface, and rapid or erratic movements (Bowles et al. 1994; Lesage et al. 1999; Williams et al. 2002; Ng and Leung 2003; Aguilar de Soto et al. 2006). These all with potentially high energetic costs (Williams et al. 2006; Koper and Plön 2012). The time period, frequency and magnitude of a behaviour modification caused by anthropogenic disturbance, with its associated long-term implications, at a population level, remains unknown, and there remains no evidence to suggest that the change in behaviour is not detrimental.

Stress caused by disturbance is associated with a change in body chemistry (Jasny et al. 2005) and can be equally disruptive as physical damage. Stress has implications on sexual maturation, inhibits growth, reproduction and general survival ability (Pickering 1992; McCormick 1999; Consten et al. 2001). Perceptual effects can occur when there is an interference of sounds of interest to a specific animal but are being drowned out or masked by anthropogenic noise. The impact of this in the long term could have implications on breeding populations, thus on reproduction within a population (Erbe 2001). Many animals may have the ability to counteract this and make minor changes to their vocalisations and behaviour; however, these modifications may come at a cost in terms of energy expenditure (Tyack 2008) and are likely to reduce breeding productivity of the population. This is of particular concern for species that are already threatened.

Barendse et al. (2010), Best & Allison (2010), and Elwen et al. (2014) highlighted that there is no existing evidence of a clear 'corridor' of migration and humpback whales appear to be spread out widely across the shelf and into deeper pelagic waters, especially during the southward migration, in the Benguela ecosystem. Despite various species being recorded frequently on the coasts and within the Exclusive Economic Zone, the location of breeding grounds of Sei (*Balaenoptera borealis*) and Fin whales (*Balaenoptera physalus*) are unknown, the seasonality of pygmy (*Kogia breviceps*) and dwarf (*Kogia sima*) sperm whales are unknown and the abundance and occurrence of the offshore common dolphin (*Delphinus delphis*) is also unknown, highlighting that encounters with these animals cannot be predicted and the generic mitigation measures may be insufficient.

In 2020, Vermeulen *et al.* warned that there is an observed decrease in Southern Right Whale calving success (i.e. low numbers of unaccompanied adults) of the South African population, with a strong link to foraging success (Vermeulen *et al.* 2023). It was highlighted that reduced maternal body condition, could contribute to a decreased reproductive rate and potentially have serious consequences for cow-calf pairs in relation to South Africa's whale-watching industry in the future. Germishuizen (2024) and Vermeulen *et al.* (2023) show that Southern Right Whales are responding to changing climate conditions by modifying foraging behaviours within their high-latitude foraging grounds. These adaptive strategies, which include altering migratory behaviours, are associated with energetic costs (Vermeulen *et al.* 2023). The consequences of these changes in energetic costs, at a population level, remain unknown.

AV

South Africa's south and west coasts are hosts to eight species of beaked whales (Ziphiidae) (Best 2007), including a new species described in 2021 (*Mesoplodon eueu;* Carroll et al. 2021), which are globally recognised as being sensitive to anthropogenic noise, and having raised conservation concerns. New et al. (2013) found that adult female beaked whales could survive but not reproduce in times or areas of lower habitat quality. They may extend the duration of lactation in mediocre conditions to increase their chance of survival, while still reproducing. New et al. (2013) found that some beaked whale species require high-quality habitat to meet their requirements for reproduction and survival. They suggested that even minor, non-lethal disturbances resulting in changes in behaviour, such as displacement from preferred habitats and stress (discussed above), could impact a population

Sea Turtles

Adult sea turtles may be less vulnerable to sound damage than cetaceans as the air spaces in their cochlear are smaller than those in cetaceans, making them less sensitive to sound shockwaves (Popper et al. 2014). However, while studies have shown that adult sea turtles have a moderate ability to move from an area being surveyed (Lenhardt 1994, O'Hara and Wilcox 1990), they are prone to Temporary Threshold Shift (TTS) after exposure to sound within 1 km of a sound source, with signs of recovery only two weeks after injury (Lenhardt 1994).

There are five resident sea turtle species that migrate around the South African coastline: Endangered green turtles (*Chelonia mydas*); Critically Endangered hawksbills (*Eretmochelys imbricata*); regionally Near Threatened loggerheads (*Caretta caretta*); regionally Critically Endangered leatherbacks (*Dermochelys coriacea*); and vagrant Vulnerable olive ridleys (*Lepidochelys olivacea*) (Le Gouvello et al., 2024).

In our opinion there is cause for concern of harm to these threatened species of sea turtles both at the population as well as the species level. Sea turtles employ nest site fidelity, essentially returning to the beach where they were born to lay eggs. In South Africa, the leatherback and loggerhead nesting trends have been monitored since 1965, within their rookeries in northern KwaZulu-Natal (KZN), giving clear indications of local population levels. Both species are already under significant pressure offshore including being caught as bycatch in fishing gear and having to contend with increasing plastic pollution. Current estimates of loggerhead turtles are low, with an estimated 801 and 615 adults nesting in the KZN rookery during the 2021/2022 and 2022/2023 seasons, respectively (Figure 1; Bachoo, 2022; Bachoo, 2024). Of more concern is the leatherback turtle, in which only 96 identified individual adults nested during the 2021/2022 season and declined to 46 individuals in 2022/2023 (Figure 2; Bachoo, 2022; Bachoo, 2024). Both populations have shown extremely slow recovery since conservation measures in South Africa were implemented, and further anthropogenic loss could, in our opinion, constitute irreparable harm.

AV

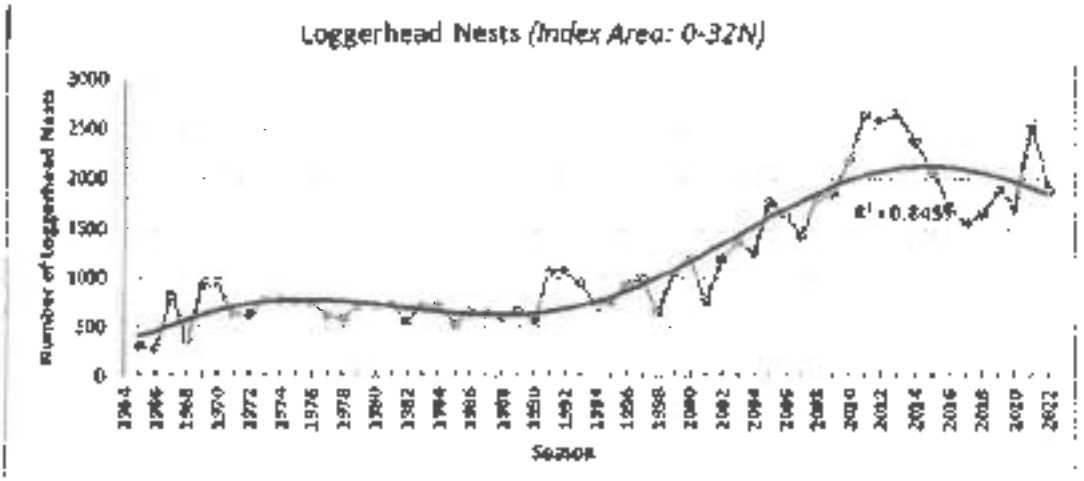

Figure 1. Number of loggerhead turtle nests in the index area (0 – 32 N) from the 1965/1966 nesting season to the 2019/2020 nesting season. From Bachoo (2022) and Bachoo (2024).

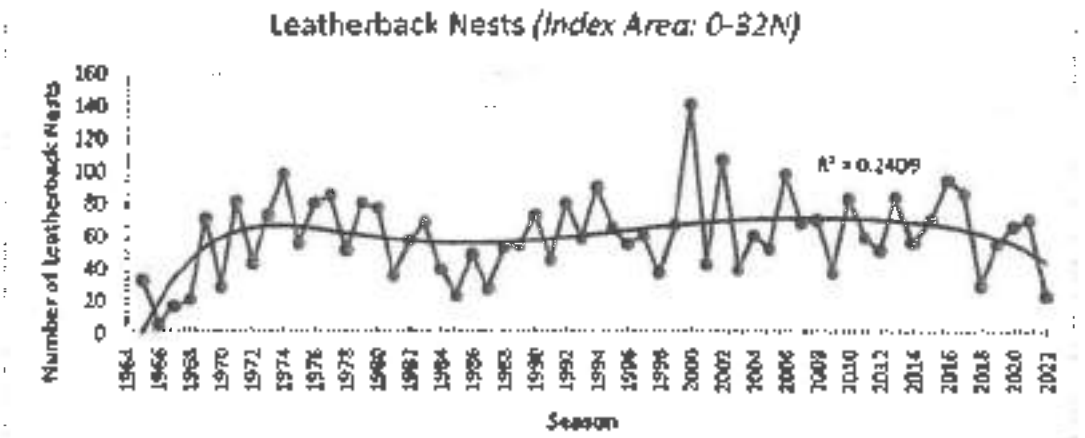

Figure 2. Number of leatherback turtle nests in the index area (0 – 32 N) from the 1965/1966 nesting season to the 2019/2020 nesting season. From Bachoo (2022) and Bachoo (2024).

The migratory lifestyle of sea turtles is mostly attributed to its complex life-cycle and their innate nature to return to their natal areas for nesting (Pendoley, 1997). Nesting of both leatherback and loggerhead turtles, on the beaches of the iSimangaliso Marine Protected Area (KwaZulu-Natal, South Africa) and Ponta do Ouro (southern Mozambique), occurs between October and March, with a peak from December to January (Table 1; Nel et al., 2013; Le Gouvello et al., 2020). Turtle hatchlings are likely to enter the ocean during the first quarter of the year, where they feed off plankton and remain in the open ocean currents until their development is complete (Luschi et al., 2003; Le Gouvello et al., 2024). It is almost impossible to track these 'tennis ball sized' hatchlings, in addition to their high mortality rates and rapid growth, further complicating the attachment of tracking devices. The result, is termed the "lost years", where it remains unclear where sea turtles <10 years old occur before returning to their shallow water foraging grounds (Musick and Limpus, 1997; Luschi et al., 2003). The movement of sea turtle hatchlings and early juveniles from coastal waters into the open pelagic ocean is strongly

AV

influenced by currents, which aid in moving them away from inshore predatory waters and prevents them from being cast higher ashore (Luschi et al., 2003). The current systems serve as the optimal environment for hatchlings and juveniles where their passive dispersal movement is a consequence of drifting (Luschi et al., 2003).

A recent scientific investigation by Le Gouvello et al. (2024) employed modelling techniques to examine the trajectory of neonate (<1 year old) turtles from hatching to one years old, using high-resolution ocean models in conjunction with particle tracking simulations. Juvenile sea turtles, both loggerhead and leatherback, leaving the iSimangaliso Marine Protected Area and Ponta do Ouro, take approximately 200-365 days to reach the west coast region (Figure 3a & 3b; Le Gouvello et al., 2024). Considering the loggerhead and leatherback movements and duration from the east coast to the west coast, raises the question of whether this can be considered a migration behaviour (Luschi et al., 2003). This means that due to the annual introduction of new hatchlings between January and March, and their movement around the coastline from east to west, it is indicative of a high likelihood that juvenile sea turtles will occur throughout the year (Table 1; Figure 3a & 3b; Le Gouvello et al., 2024).

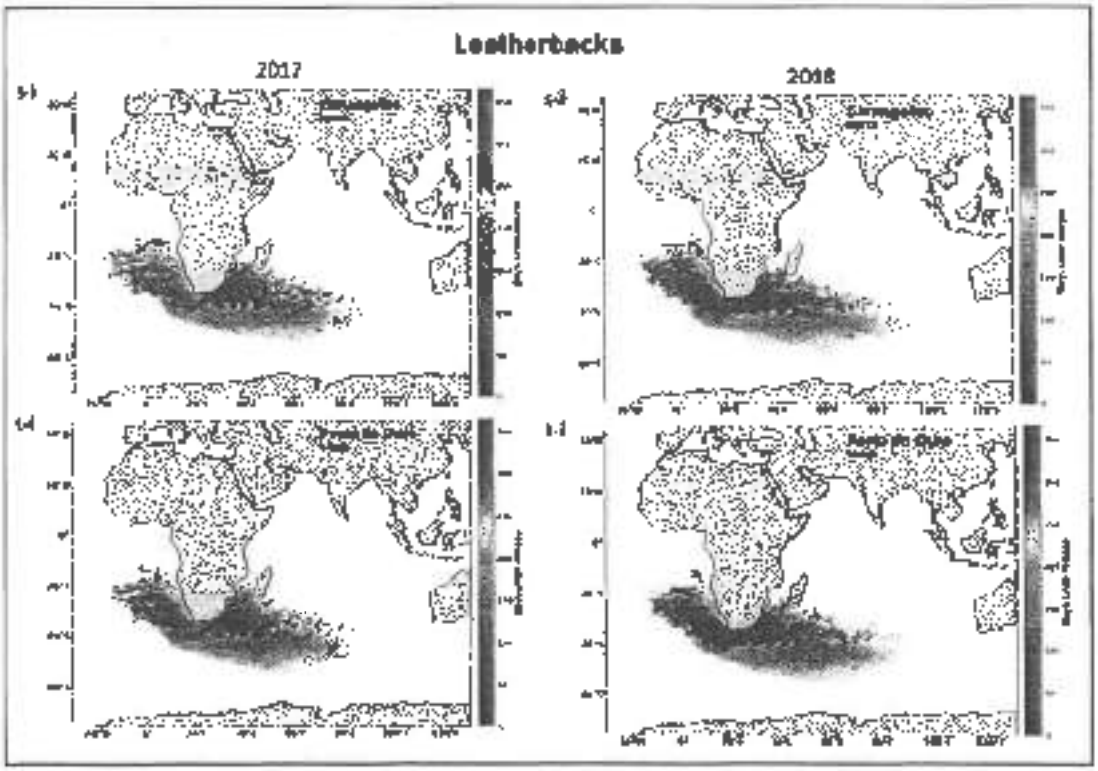

Figure 3a: Dispersal maps showing 12 month trajectories of 5000 particles released from the respective nesting sites (white circles) of leatherbacks in 2017 (-i) and 2018 (-ii) from two rookeries (iSimangaliso MPA and Ponta do Ouro). Colours (blue to red) indicate the number of days since release, and grey text gives the month of release. From Le Gouvello et al. 2024.

AV

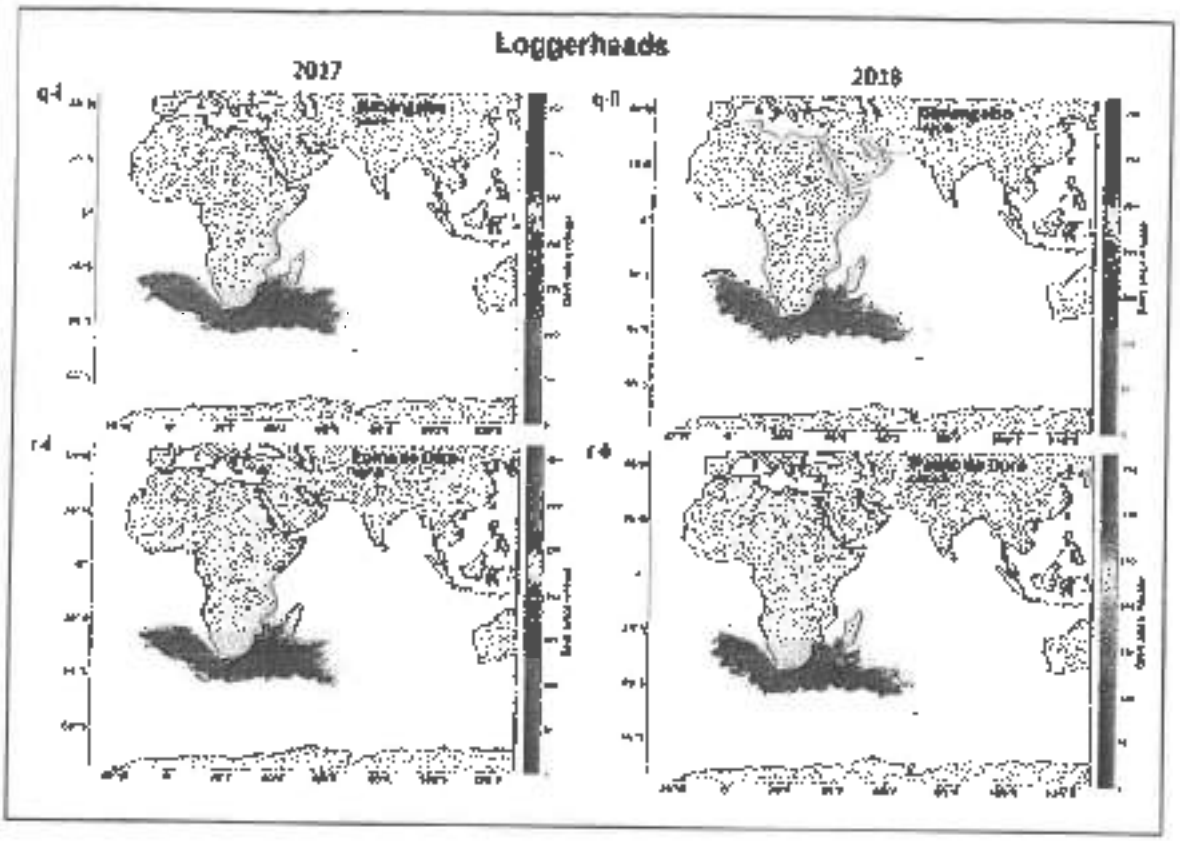

Figure 3b: Dispersal maps showing 12-month trajectories of 5000 particles released from the respective nesting sites (white circles) of loggerheads in 2017 (-I) and 2018 (-II), from two rookeries (iSimangaliso MPA and Ponta do Ouro). Colours (blue to red) indicate the number of days since release, and grey text gives the month of release. From Le Gouvello et al. 2024.

Satellite tracking data of stranded, rehabilitated and released sea turtles of various species (loggerhead, green, olive ridley) and sizes (juvenile to sub-adult) further confirms their presence on the west coast year-round (Two Oceans Aquarium Foundation, Bayworld, Port Elizabeth and South African Association for Marine Biological Research, unpublished data; Figure 4a, 4b, 4c). The routes of sea turtles from satellite tracking often show direct paths to their destination, but individual turtles may only arrive at their destination after a long detour, making their movements unpredictable.

Images from Two Oceans Aquarium Foundation, Bayworld, Port Elizabeth and South African Association for Marine Biological Research, unpublished data; Talitha Noble-Trull, Pers. comm.).

AV

The presence of sea turtles at different stages in their life history, are present throughout the year along the west coast and likely within the AOI. (Table 1; Le Gouvello et al. 2024; Satellite tracking data, Bayworld, Port Elizabeth and South African Association for Marine Biological Research, unpublished data).

Table 1. Presence and location of sea turtles each month occurring on the southern African nesting beaches and in the area of interest (AOI) throughout the year based on local literature.

	J	F	M	A	M	J	J	A	S	O	N	D
Nesting period												
Hatchling period												
Presence of post-hatchling & immature sea turtles within the AOI (based on Le Gouvello et al, 2024)												

These sea turtles live out their early years on and close to the surface, only being able to dive to depths of 2-3 m. These juveniles and hatchlings cannot swim effectively or fast enough away if in close proximity to the sound source. Up to now, there are no effective mitigation measures which can be offered to mitigate the impact of sound/airgun blasts on the smaller turtles, and this is of extreme concern, not only due to their inability to evade the radius of blasts, but also since they will not be readily visible to visual observers due to their small size and behaviour in the water. Given that the success rate of visual observations by MMOs for large species such as humpback whales is only 44% of the time (Wilkinson, 2021), it renders this method of mitigation ineffective for smaller animals such as sea turtles, but especially for post-hatchling (palm-sized) and juvenile (dinner plate-sized) turtles. The difficulty in visually detecting these animals in the offshore environment is further corroborated by turtle researchers (Musick and Limpus 1997).

A further potential physical impact for sea turtles from seismic surveys is entanglement and/or entrapment in equipment (Nelms et al., 2016). It was noted by Weir et al. (2007) that off the west coast of Africa prior to the turtle nesting season, an influx of sea turtles are observed during seismic surveys, as well as in the vicinity of seismic vessels and its towed equipment (Ketos Ecology (2009). Turtles tend to bask on the ocean surface to slow down metabolic processes and conserve energy during hot and favourable weather conditions (Ketos Ecology, 2009). Therefore, turtle startle dive responses to seismic vessels and equipment may be delayed and occur only after visual detection of approaching objects at close range (< 1 m) (Ketos Ecology, 2009). This basking behaviour of turtles can leave them vulnerable to collisions with dik floats and tail buoys, which are usually located several kilometres astern the ship and pose a challenge of observing and monitoring for turtle entrapments (Ketos Ecology, 2009). In addition, loggerhead, olive ridley and Kemp's ridley (*Lepidochelys kempii*) are likely species falling victim to tail buoy entrapments while foraging alongside a seismic cable, inevitably causing the fatality of trapped turtles (Ketos Ecology, 2009).

Their presence, coupled with an inability to mitigate the risk of seismic surveys on sea turtles, means that post-hatchling and juvenile sea turtles are at significant risk of harm. Furthermore, with their limited ability to swim and avoid obstacles, pelagic loggerhead and leatherback juvenile turtles are highly vulnerable to seismic surveys because of direct injury or mortality from the towed hydrophone

AV

streamers (Le Gouvello et al., 2024). In 2020, Le Gouvello et al. reported that female loggerhead turtle size is declining in South Africa, even though their nesting grounds are protected. Therefore, population growth is not always guaranteed if survival is not ensured at other life stages at sea (Crouse et al. 1987; Crowder et al. 1994; Chaloupka and Limpus 2001; Bjorndal et al. 2005; Margaritoulis 2005; Mazaris et al. 2006), and although coastal marine protected areas do work in protecting sea turtles (Nel et al., 2013, Le Gouvello et al., 2020) there is a need for integrated management strategies (Le Gouvello et al., 2020), to protect threatened species.

CONCLUSION

For the reasons outlined above, it is our opinion that the proposed seismic surveys for reconnaissance pose an unacceptable acoustic and ecological risk to the marine ecosystems and species in South African waters. In point 3.2 of the EA, seismic surveys are described as "*generally regarded as non-intrusive in nature*", and although states that "*the technology poses potential impacts on fisheries and marine fauna,…..the majority of the impacts were assessed to range between low to very low significance with mitigation*". In our opinion, the acute anthropogenic noise over a prolonged period of time, and the extensive survey gear in the water is an ecological risk to threatened and protected marine fauna that primarily use sound to survive and/or are unable to avoid the area of impact. We therefore disagree with the finding of the BAR and Reasons for Decision in the EA, that seismic surveys are regarded as 'non-intrusive', especially when the report clearly acknowledges the presence of impacts, before assessing their significance as low despite the impacts being largely unknown.

Curriculum Vitae

JEAN MARY HARRIS

PERSONAL DETAILS

Name	:	Jean Mary Harris
Birth date	:	28 December 1962
ID Number	:	6212280006086
Place of birth	:	Johannesburg
Nationality	:	South African
Race	:	White
Gender	:	Female
Address	:	49 Natford, Bluff, Durban, 4052, KZN South Africa
Tel	:	+27-61-4219638 (w), 082-4954416
e-mail	:	jeanjh@wildtrust.co.za or jmharris@iafrica.com

EDUCATION

1993 PhD (Zoology), University of Cape Town. Focus: Trophic ecology in estuarine and intertidal systems.
1984 B.Sc. Hons. (Marine Biology), University of Cape Town, First Class
1982 B.Sc. (Zoology), University of Cape Town
1979 Matriculated, A-grade, Clarendon Girls High School, East London

AWARDS:

- PEW Fellowship in Marine Conservation, 2000
- Purcell Memorial Prize for best Zoology PhD thesis, 1993
- FRD Special Merit Doctoral Award, 1990

SELECTION OF PROFESSIONAL OFFICES HELD

Pew Fellow in Marine Conservation, Pew Fellows Program in Marine Conservation, 2000 - present
Trustee: South African Association for Marine Biological Research, 2016- July 2017
Member: Programme Steering Committee for the Marine Science for Management Association (MASMA), Western Indian Ocean Marine Science Association (WIOMSA) 2004-2015.
Chair: Subsistence Fisheries Task Group 1999-2000.
Chair: SA Network for Coastal and Oceanographic Research (SANCOR) National Steering Committee 1997-2001.
Member: IUCN Species Survival Commission – Marine Conservation Committee, 2018-present
Member: IUCN SSC Red List Committee, 2018-2021
Executive Trustee: Wildlands Conservation Trust, 2015- April 2017
Member: Scientific Authority 2014-2017. Advises the SA Minister of Environment on biodiversity matters
Chair: Symposium of Contemporary Conservation Practice (SCCP) 2012- July 2017.
Member: East African Marine EcoRegion Programme Committee (EAME) 2004-2010

EMPLOYMENT RECORD

Strategic Ocean Lead, WILDOCEANS, Wildlands Conservation Trust, August 2017 - current
Research Associate, Institute for Coastal and Marine Research, **Nelson Mandela University**, 2016-present
Senior General Manager: Scientific Services, Ezemvelo KZN Wildlife, October 2006 – July 2017
Ecological Advice Co-ordinator, Coast Region, Ezemvelo KZN Wildlife, 2002- September 2006
Regional Ecologist Marine/Scientist, Scientific Services, KZN Nature Conservation Service, 1995 – 2002
Senior Scientific Officer, Terrestrial Antarctic Biology Research Programme, Ornithology, UCT, 1991-1994

SELECTION OF RESEARCH AND MANAGEMENT EXPERIENCE

Project Leader Blue Action Fund uThukela MPA Ecosystem-based Adaptation Project (2023-current): This project is aimed at the protection and restoration of important ecosystems in new uThukela Banks Marine Protected Area, and associated estuarine functional zones, reducing climate-related socio-ecological risk.
Project Leader Blue Action Fund "Oceans Alive" iSimangaliso MPA Project (2019-current): This project has 3 main objectives 1) Build knowledge of the biodiversity and socio-economics of the MPA and its communities, 2) Support effective management of the iSimangaliso MPA, and 3) Ensure benefits and improved livelihoods for rural communities living alongside the iSimangaliso MPA.
Directs the following WILDOCEANS projects for the WILDTRUST (2017-current): Ocean Stewards, WhaleTime, MPA Expansion Project, Shark and Ray Conservation Project, Comoros Fish and Benthic Biodiversity Project, iSimangaliso Oceans Alive (MPA expansion, effective management and benefits to communities) Project, Blue Crew project in the Durban bay estuarine environment (plastic pollution action), Oil spill modelling and risk assessment projects, inshore bottom-trawling assessment project, small-scale fisheries support project..
Principle Investigator and Co-ordinator for NRF-funded African Coelacanth Ecosystem Programme research projects: uThukela MPA SmartZone (2020-2023), Biodiversity Surrogacy (2014-2017), Spatial Solutions (2016-2018) and Canyon Connections (2018-2020). Offshore biodiversity survey and sampling to test validity of modelled biozones, to refine conservation planning, and to support marine protected area expansion and the National Biodiversity Assessment (CBD).
Project leader for WWF-SA, NRF and ACEP funded project: SeaPLAN – development of a systematic conservation plan for the east coast of south Africa (2004-2012). Integrates shoreline biodiversity mapping, reef biodiversity surveys and key species and processes.
Project leader Wildlands Trust funded project: Rare and Endangered Species of the Greater St Lucia Wetland Park (2002-2006). This project aims to update the records of these species in the park and provide a management handbook. It is focussed on terrestrial and freshwater wetland species and employs a full-time researcher. This project has become entrenched and is ongoing.
Project leader for NRF funded project: KwaZulu-Natal and Transkei indigenous knowledge of subsistence harvesters (2002-2006): Aims to document traditional knowledge and management systems of rural subsistence harvesters, compare regional differences, and integrate into current management practices.
Chairperson of Subsistence Fisheries Task Team, on behalf of Marine and Coastal Management (DEAT), managed a national programme for coast-wise identification of and consultation with subsistence fishers (1999-2000). Acted as Program manager and supervisor of 8 Regional Fieldworkers (Northern Cape, West Cape (x2), South coast, Eastern Cape (x2), KwaZulu-Natal (x2), and a National Co-ordinator and project researcher. – Project leader and finance vote-holder (ca R1 mill)
Project executant (co-ordinator & researcher, and supervisor of 2 project staff) for 5-year project funded by The Green Trust, WWF-SA: The development of sustainable utilization of mussels by artisanal and subsistence gatherers along the northern KwaZulu-Natal coast – Sokhulu community alongside iSimangaliso 1995-2000.

POST-GRADUATE STUDENT SUPERVISION:
6 MSc and 2 PhD students

PUBLICATION SUMMARY:

Papers in refereed journals:	37
Book/ book chapter	9

SKILLS

- Class IV Commercial Diver,
- SAMSA Skipper - Category C (Surf Launch)
- SAMSA Short Range VHF Radio Operators Certificate
- First aid - Level 3 (in-date).
- Quantum GIS (2015)

Profile

I have practised as a marine conservation biologist for over 20 years with a keen interest in marine biodiversity, policy development and law enforcement. While conducting applied research that identifies anthropogenic threats and risks to species, I aim to provide solutions to reduce habitat degradation, biodiversity loss and illegal trade risk. I possess essential scientific, technical and reporting skills with two decades of experience in project development, data collection, statistical analyses and reporting in multidisciplinary projects, in both the government and NGO sectors. Projects I have worked on have required coordination and facilitation with various stakeholders, government entities and the public. This resume validates my excellent work ethic and personal attributes, including sound organizing, time management and planning skills, together with the ability to work independently or in a team. I obtain a great deal of satisfaction in that there is rarely a dull moment in conservation, and very little remains static from day to day.

Education

PhD (Zoology) - 2016
University of Cape Town, South Africa.
Taxonomy, biodiversity and biogeography of the brittle stars (Echinodermata: Ophiuroidea) of South Africa.

MSc (Biological Sciences) - 2007
University of KwaZulu-Natal, Oceanographic Research Institute.
Zonation of the benthic communities on Aliwal Shoal, KZN, South Africa.

BSc Hons (Marine Ecology) - 2003
University of Natal, Durban.
Age, growth and stock assessment of Otolithes ruber from KwaZulu-Natal, South Africa.

BSc degree (Natural and Environmental Sciences) - 2002
Rand Afrikaans University.

Certificate in Environmental Law and Liabilities for the Regulated Community - 2019
University of South Africa.

Certificate in Environmental Law & Environmental Management Legal Enforcement - 2023
University of South Africa.

Employment History

WILDOCEANS, a programme of the WILDTRUST | Senior Marine Scientist | August 2022 - Present
Provide scientific oversight in shark and ray conservation-based projects, while contributing to overall scientific support and mentorship in several marine projects within WILDOCEANS.

AV

24.00

Duties: the focus of my duties within the shark and ray projects, namely, *Securing protection for sharks and rays in South African waters* (funded by the Shark Conservation Fund) and the *Sanctuary for Sharks and Rays Project* (funded by the Rainforest Trust), was to ensure scientific rigor and oversight in the information provided by the project to the Department of Forestry, Fisheries and the Environment, while creating information and collating existing knowledge to increase the statutory protection for sharks and rays, with emphasis on threatened and endemic species. Some aspects of the projects are policy-focused, where modifying current legislation and regulations for further protection of shark and ray species is required while increasing spatial protection (through the formation of new no-take marine protected areas within South Africa's mainland Exclusive Economic Zone. The projects also required content creation for awareness and education via their campaigns, namely *Sharks Under Attack* and *On the Brink*, with a focus on changing the public's perception of sharks as dangerous, to a better understanding of this imperilled species globally.

Additional components of these projects is to achieve effective implementation and enforcement of adopted conservation and management measures, through training and support of law enforcement officials within various aquatic units and ports of entry (i.e. SAPS, Metro Police, SARS Customs and conservation agencies including Ezemvelo KZN Wildlife, Cape Nature, SANParks and Border Management Agency), specifically in environmental law, illegal gill-netting, use of drones, and the shark fin trade.

Further to this, during my time at WILDTRUST, I have supervised students academically (4x MSc; 1x BSc Hons), while managing and mentoring several interns (x2) and junior staff (x3).

Ezemvelo KZN Wildlife | Marine Ecologist | 2007 - 2020.

While at Ezemvelo, I was required to provide ecological advice and decision support to conservation managers on priority biodiversity information needs in the province of KwaZulu-Natal (KZN). Develop and implement long-term monitoring programmes for several marine ecosystems and resources, including subtidal reefs, rocky shores, sandy beaches, nesting turtles, humpback whale migration, marine stranded animals, shark diving and non-consumptive resource use. I also contributed to policy development and legislation tackling marine conservation concerns, while providing training to field staff on aspects of marine protected areas, threatened and protected species and various marine resources. I also liaised with several external organisations and government departments on issues relating to marine research and the marine environment, while representing the province of KZN in marine conservation on several National working groups, i.e. Top Predator Working Group and Marine Alien Invasive Working Group.

During my tenure at Ezemvelo, I created, implemented and coordinated a marine animal stranding Network for KZN, where all stranded animals, including turtles, cetaceans (whales and dolphins), pinnipeds (seals), and sea- and coastal birds, were managed through rescue, rehabilitation and/or disposal. The KZN Marine Stranding Network continues to be supported by over 25 affiliates and organisations.

Oceanographic Research Institute | Research Assistant | 2006.

Sort, process and identify benthic samples, including data capture and maintain a benthic reference collection database.

Oceanographic Research Institute | MSc Fellowship | 2004 - 2005.

In addition to completing an MSc, maintain the Oceanographic Research Institute research aquarium, capture data for the east coast reef survey project and assist with oyster, crayfish and mud prawn surveys.

IUCN Shark Specialist Group | Workshop assistant

Batoid Workshop - September 2003.

Sub-Equatorial Africa Workshop - September 2004.

General and administrative assistance for the duration of the workshop, and aid in documenting elasmobranchs for IUCN red data list criteria.

KENDYL ANDREA WRIGHT

SYNOPSIS

Dr. Kendyl Wright is a dedicated marine biologist committed to marine conservation. Currently, she holds the position of Marine Protected Area Scientist at WILDTRUST, WildOceans Programme. Dr. Wright is a passionate advocate for expanding marine protection, actively contributing to the discourse on the need for safeguarding the marine environment. Having earned her Ph.D. in Benthic Ecology, Dr. Wright has diverse experience in both the private and non-governmental organization sectors. Initially specializing in coastal ecology and nearshore benthic habitat research, she has transitioned into the realm of Marine Protected Area science, policy, and planning. Currently, Dr. Wright is engaged in various Marine Protected Area (MPA) projects spanning South Africa and the Western Indian Ocean. Her focus extends to community and small-scale fisher engagement, reflecting her keen interest in fostering inclusive conservation efforts. A competent passionate ocean enthusiast, she has experience diving, power boating, sailing and surfing.

2021-Current: Sanctuary Project for Sharks and Rays – MPA Scientific Lead

Following the development of a Systematic Conservation Plan identifying priority areas for South Africa's MPA network, led the implementation of spatial protection measures for sharks, rays, skates, and chimaeras, with a focus on threatened and endemic species. Contributing to the future expansion of MPA's in South Africa and addressing the vulnerability of these species due to slow growth, late maturity, and dependence on critical habitats.

2023-Current: Small-scale Fishers and Marine Protected Areas – Scientific Lead

Currently providing the scientific and strategic support for a project aimed at improving the management and sustainability of small-scale fisheries in South Africa, fostering positive relationships between marine protected areas (MPAs) and rural fishers dependent on natural resources for livelihoods and food security. Focused on iSimangaliso and uThukela MPAs, the project, funded by the Blue Action Fund, is attempting to establish co-management systems between MPA managers and fishers, with community-based monitoring in defined co-management zones. Targeting rural subsistence fishing communities, providing practical support for improved fisheries management and sustainable resource use.

2023-Current: Sustainable Finance in Support of 30x30 – Scientific Lead

Providing marine expertise in support of a large team exploring the financial sustainability of marine protected and conserved areas (PCAs) within South Africa. This has included supporting a Finance Needs Assessment of current financial needs and future requirements related to 30x30 conservation targets. In addition, more focused work is being undertaken within the iSimangaliso MPA to develop sustainable financing strategies, supporting the long-term viability of PCAs.

2018-2022: The South Africa MPA Expansion Project – Scientific Lead

A project funded by Oceans 5 aimed at unlocking the MPA expansion process in South Africa by way of a high-profile, intensive, and multi-faceted Campaign to increase MPA coverage of the mainland EEZ from 0.4% to 5% and to pave the way towards 10%. This campaign was based on the best available science and succeeded in supporting active expansion of MPAs and by advocating for the South African government to commit to ambitious international targets including the Kunming-Montreal Global Biodiversity Frameworks, and most pertinently target 3 or 30x30.

2014-2019: Identification of macrozoobenthic zonation and ecosystem linkages in the iSimangaliso Wetland Park – Phd Dissertation

Dr. Wright spent a year sampling the nearshore macrobenthos inshore of 2-Mile Reef in Sodwana Bay, KwaZulu-Natal. An area that is not well studied, she hoped to provide improved insight into biodiversity in the region. She is currently compiling two scientific papers for publication from her doctoral thesis, allowing for improved management in the region.

2016: KwaZulu-Natal Environmental Outlook Report – Marine Specialist Component

In order to align with government legislation, a specialist report assessing the current state and pressures experienced by the KZN coastal environment was compiled. Indicators to assess the impact of these pressures

AV

KENDYL ANDREA WRIGHT

were outlined for monitoring purposes. The specialist report provided improved decision-making capabilities at all levels of government.

2013-2014: Richards Bay Oil Spill and Subsequent Mangrove Monitoring, Contractual Consultant

Following a crude oil spill within Richards Bay harbour, assistance and advice were sought for the implementation of a clean-up strategy and a monitoring plan. Dr. Wright spent time in the field, assisting in the management of staff tasked with the clean-up. She also undertook the post-clean-up monitoring of the mangroves.

2015: Mhlanga Estuarine Assessment, KwaZulu-Natal, Contractual Consultant Anchor Environmental:

An estuarine assessment was undertaken for a Water Use License Application to permit discharge from a Waste Water Treatment Facility. Dr. Wright undertook the identification of the invertebrates and compiled the specialist report.

Environmental Impact Assessment

2013 – 2014: BrightSource Kalahari Solar Energy Power Project, Assistant Consultant:

Scoping and Environmental Impact Assessment for the installation of a Solar Power Plant in Upington, Northern Cape.

2012 - 2014: Illovo Sugar South Africa (Pty) Ltd, Proposed Green Boiler Project, Assistant Consultant.

Scoping and environmental impact assessment for the construction of boilers at Eston and Noodsberg to convert bagasse to energy for export to the national grid. Assistant consultant in stakeholder engagement and report writing

Environmental Screenings

2012 – Africa Sun Oil, Environmental Screening of a Proposed Shopping Centre, Reservoir Hills, Consultant.

Environmental Screening of the proposed new Reservoir Hills Shopping Centre based on virgin land, including the identification of potential impacts or areas of concern.

ANNEX B5

"CJM 1"

Saldanha TGS interaksie

18 May 2023

Ons as die vissers van Saldanha het n vergadering met EIMS by hoedjies baai Hotel vir TGS bygewoon en ons het die volgende met hulle gedeel. Ons as visser is gekant teen alle forms van Olie en Gas in oseane vir die volgende redes. Die vis species wat tans folop is sal uitgeroei word en ons ervaring is dat hierdie vis spesies al reeds skaars as gevolg van klimaats verandering. Olie/Gas Drilling is n bedreiging vir alle marine spesies in die oseane. Dit gaan ons vissers voortbestaan verder in armoed dompel. Ons will dit pertinent stel van Noord tot Wes, Suid en Oos,ons is bank vas gekant teen Olie en Gas en ons weier om ons oseane beskikbaar te stell vir enige Olie en Gas. Hierdie vergadering was nie goed bygewoon die deur die bree gemeenskap nie en ons wonder was daar nog soort gelyke opvolg vergaderings gehou

Opvolg verslae:

Ons as die vissers, en Ek spesifiek wat by die vergadering was van TGS het geen terugvoering ontvang vanaf TGS tot kennisgewing 26 April 2023. Ons as Visser drae nie kennis van verslae wat in biblioteek of ander plekke was nie.Ons het nie geleenheid gehad om seker te maak dat ons kommentaar well akuraat opgeteken was nie en dra nie kennis hoe hulle ons kometaar beantwoord het nie.

Baie Dankie

Carmerlita Mostert

CURRICULUM VITAE

Jackie Sunde

Current Bio

I am a researcher and activist in South Africa working with small-scale fishing communities. I undertake research and training on marine and fisheries governance and work closely with fishers in all four provinces in South Africa and have a particular interest in supporting fishing communities in their struggle for the recognition of their customary fishing rights and in highlighting the intersection of human rights and marine biodiversity protection.

Personal details

Name: Dr Jacqueline Sunde (Jackie)
Address: 38 Peak Rd, Fish Hoek, Cape Town 7975
Telephone: Mobile: 072 262 7444
Email: jacklesunde25@gmail.com
Date of Birth: 25 April 1963 Born in South Africa

Relevant Educational Qualifications

2014 PhD. University of Cape Town, South Africa
1990 Master of Arts (Women's Studies), University of York, UK

Relevant Employment

Current – Independent Researcher
Dec 2019 to June 2024 – Senior Researcher, One Ocean Hub Research Team, Dept of Environmental and Geographical Science, University of Cape Town
July 2018 – July 2019 – Gender and Learning Advisor, ABALOBI Fisheries Organisation
2017 – 2018 Independent researcher and consultant on Small-scale Fisheries and Marine and Coastal Governance
2010-2017 Part-time contract researcher and Phd. candidate, Dept Environmental and Geographical Science, University of Cape Town
Sept 2008 - 2010 Research and Advocacy Coordinator, Masifundise Development Trust
2002 - Sep 2003 Program Manager Masifundise Development Trust
2001 Social Development and Gender Consultant contracted to the Human Rights and Poverty Directorate, Provincial Administration of the Western Cape.
2000 Contract Lecturer Department of Social Development University of Cape Town
1995 – 1999 Researcher, Centre for Rural Legal Studies,
1994 - 1995 Assistant Lecturer University of Cape Town, South Africa
1991-1993 Social Worker – Child Protection Department, Child Welfare Society
