B.2.4 Regions and people with considerable development constraints have high vulnerability to climatic hazards *(high confidence)*. Global hotspots of high human vulnerability are found particularly in West-, Central- and East Africa, South Asia, Central and South America, Small Island Developing States and the Arctic *(high confidence)*. Vulnerability is higher in locations with poverty, governance challenges and limited access to basic services and resources, violent conflict and high levels of climate-sensitive livelihoods (e.g., smallholder farmers, pastoralists, fishing communities) *(high confidence)*. Between 2010–2020, human mortality from floods, droughts and storms was 15 times higher in highly vulnerable regions, compared to regions with very low vulnerability *(high confidence)*. Vulnerability at different spatial levels is exacerbated by inequity and marginalization linked to gender, ethnicity, low income or combinations thereof *(high confidence)*, especially for many Indigenous Peoples and local communities *(high confidence)*. Present development challenges causing high vulnerability are influenced by historical and ongoing patterns of inequity such as colonialism, especially for many Indigenous Peoples and local communities *(high confidence)*. {4.2, 5.12, 6.2, 6.4, 7.1, 7.2, Box 7.1, 8.2, 8.3, Box 8.4, Figure 8.6, Box 9.1, 9.4, 9.7, 9.9, 10.3, 10.4, 10.6, 12.3, 12.5, Box 13.2, 14.4, 15.3, 15.6, 16.2, CCP6.2, CCP7.4}

B.2.5 Future human vulnerability will continue to concentrate where the capacities of local, municipal and national governments, communities and the private sector are least able to provide infrastructures and basic services *(high confidence)*. Under the global trend of urbanization, human vulnerability will also concentrate in informal settlements and rapidly growing smaller settlements *(high*

31 Governance: The structures, processes and actors through which private and public actors interact to address societal goals. This includes formal and informal institutions and the associated norms, rules, laws and procedures for deciding, managing, implementing and monitoring policies and measures at any geographic or political scale, from global to local.

32 Balanced diets: Balanced diets feature plant-based foods, such as those based on coarse grains, legumes, fruits and vegetables, nuts and seeds, and animal-source foods produced in resilient, sustainable and low-greenhouse-gas-emitting systems, as described in SR2CCL.

confidence). In rural areas vulnerability will be heightened by compounding processes including high emigration, reduced habitability and high reliance on climate-sensitive livelihoods (*high confidence*). Key infrastructure systems including sanitation, water, health, transport, communications and energy will be increasingly vulnerable if design standards do not account for changing climate conditions (*high confidence*). Vulnerability will also rapidly rise in low-lying Small Island Developing States and atolls in the context of sea level rise and in some mountain regions, already characterised by high vulnerability due to high dependence on climate-sensitive livelihoods, rising population displacement, the accelerating loss of ecosystem services and limited adaptive capacities (*high confidence*). Future exposure to climatic hazards is also increasing globally due to socioeconomic development trends including migration, growing inequality and urbanization (*high confidence*). (4.5, 5.5, 6.2, 7.2, 8.3, 9.9, 9.11, 10.5, 10.6, 12.3, 12.5, 13.6, 14.5, 15.3, 15.4, 16.5, CCP2.3, CCP4.5, CCP5.2, CCP5.3, CCP5.4, CCP6.2, CCB MIGRATE)

Risks in the near term (2021–2040)

B.3 Global warming, reaching 1.5°C in the near-term, would cause unavoidable increases in multiple climate hazards and present multiple risks to ecosystems and humans (*very high confidence*). The level of risk will depend on concurrent near-term trends in vulnerability, exposure, level of socioeconomic development and adaptation (*high confidence*). Near-term actions that limit global warming to close to 1.5°C would substantially reduce projected losses and damages related to climate change in human systems and ecosystems, compared to higher warming levels, but cannot eliminate them all (*very high confidence*). (Figure SPM.2, Box SPM.1) (16.4, 16.5, 16.6, CCP1.2, CCP5.3, CCB SLR, WGI AR6 SPM B1.3, WGI AR6 Table SPM.1)

B.3.1 Near-term warming and increased frequency, severity and duration of extreme events will place many terrestrial, freshwater, coastal and marine ecosystems at high or very high risks of biodiversity loss (*medium to very high confidence*, depending on ecosystem). Mass-term risks for biodiversity loss are moderate to high in forest ecosystems (*medium confidence*), kelp and seagrass ecosystems (*high to very high confidence*), and high to very high in Arctic sea-ice and terrestrial ecosystems (*high confidence*) and warm-water coral reefs (*very high confidence*). Continued and accelerating sea level rise will encroach on coastal settlements and infrastructure (*high confidence*) and commit low-lying coastal ecosystems to submergence and loss (*medium confidence*). If trends in urbanisation in exposed areas continue, this will exacerbate the impacts, with more challenges where energy, water and other services are constrained (*medium confidence*). The number of people at risk from climate change and associated loss of biodiversity will progressively increase (*medium confidence*). Violent conflict and, separately, migration patterns, in the near-term will be driven by socioeconomic conditions and governance more than by climate change (*medium confidence*). (Figure SPM.3) (2.5, 3.4, 4.5, 6.2, 7.3, 8.7, 9.2, 9.9, 11.6, 12.5, 13.6, 13.10, 14.6, 15.3, 16.5, 16.6, CCP1.2, CCP2.1, CCP2.2, CCP5.3, CCP6.2, CCP6.3, CCB MIGRATE, CCB SLR)

B.3.2 In the near term, climate-associated risks to natural and human systems depend more strongly on changes in their vulnerability and exposure than on differences in climate hazards between emissions scenarios (*high confidence*). Regional differences exist, and risks are highest where species and people exist close to their upper thermal limits, along coastlines, in close association with ice or seasonal rivers (*high confidence*). Risks are also high where multiple non-climate drivers persist or where vulnerability is otherwise elevated (*high confidence*). Many of these risks are unavoidable in the near-term, irrespective of emissions scenario (*high confidence*). Several risks can be moderated with adaptation (*high confidence*). (Figure SPM.3, Section C) (2.5, 3.3, 3.4, 4.5, 6.2, 7.1, 7.3, 8.2, 11.6, 12.4, 13.6, 13.7, 13.10, 14.5, 16.4, 16.5, CCP2.2, CCP4.3, CCP5.3, CCB SLR, WGI AR6 Table SPM.1)

B.3.3 Levels of risk for all Reasons for Concern (RFC) are assessed to become high to very high at lower global warming levels than in AR5 (*high confidence*). Between 1.2°C and 4.5°C global warming level very high risks emerge in all five RFCs compared to just two RFCs in AR5 (*high confidence*). Two of these transitions from high to very high risk are associated with near-term warming: risks to unique and threatened systems at a median value of 1.5 [1.2 to 2.0] °C (*high confidence*) and risks associated with extreme weather events at a median value of 2.0 [1.8 to 2.5] °C (*medium confidence*). Some key risks contributing to the RFCs are projected to lead to widespread, pervasive, and potentially irreversible impacts at global warming levels of 1.5–2°C if exposure and vulnerability are high and adaptation is low (*medium confidence*). Near-term actions that limit global warming to close to 1.5°C would substantially reduce projected losses and damages related to climate change in human systems and ecosystems, compared to higher warming levels, but cannot eliminate them all (*very high confidence*). (Figure SPM.3b) (16.5, 16.6, CCB SLR)

Mid to Long-term Risks (2041–2100)

B.4 Beyond 2040 and depending on the level of global warming, climate change will lead to numerous risks to natural and human systems (*high confidence*). For 127 identified key risks, assessed mid- and long-term impacts are up to multiple times higher than currently observed (*high confidence*). The magnitude and rate of climate change and associated risks depend strongly on near-term mitigation and adaptation actions, and projected adverse impacts and related losses and damages escalate with every increment of global warming (*very high confidence*). (Figure SPM.3) (2.5, 3.4, 4.4, 5.2, 6.2, 7.3, 8.4, 9.2, 10.2, 11.6, 12.4, 13.2, 13.3, 13.4, 13.5, 13.6, 13.7, 13.8, 14.6, 15.3, 16.5, 16.6, CCP1.2, CCP2.2, CCP3.3, CCP4.3, CCP5.3, CCP6.3, CCP7.3)

B.4.1 Biodiversity loss and degradation, damages to and transformation of ecosystems are already key risks for every region due to past global warming and will continue to escalate with every increment of global warming (*very high confidence*). In terrestrial ecosystems, 3 to 14% of species assessed[33] will *likely* face very high risk of extinction[34] at global warming levels of 1.5°C, increasing up to 3 to 18% at 2°C, 3 to 29% at 3°C, 3 to 39% at 4°C, and 3 to 48% at 5°C. In ocean and coastal ecosystems, risk of biodiversity loss ranges between moderate and very high by 1.5°C global warming level and is moderate to very high by 2°C but with more ecosystems at high and very high risk (*high confidence*), and increases to high to very high across most ocean and coastal ecosystems by 3°C (*medium to high confidence*, depending on ecosystem). Very high extinction risk for endemic species in biodiversity hotspots is projected to at least double from 2% between 1.5°C and 2°C global warming levels and to increase at least tenfold if warming rises from 1.5°C to 3°C (*medium confidence*). (Figure SPM.3c, d, f) (2.4, 2.5, 3.4, 3.5, 12.3, 12.5, Table 12.6, 13.4, 13.10, 16.4, 16.6, CCP1.2, Figure CCP1.6, Figure CCP1.7, CCP5.3, CCP6.3, CCB PALEO)

B.4.2 Risks in physical water availability and water-related hazards will continue to increase by the mid- to long-term in all assessed regions, with greater risk at higher global warming levels (*high confidence*). At approximately 2°C global warming, snowmelt water availability for irrigation is projected to decline in some snowmelt dependent river basins by up to 20%, and global glacier mass loss of 18 ± 13% is projected to diminish water availability for agriculture, hydropower, and human settlements in the mid- to long-term, with these changes projected to double with 4°C global warming (*medium confidence*). In Small Islands, groundwater availability is threatened by climate change (*high confidence*). Changes to streamflow magnitude, timing and associated extremes are projected to adversely impact freshwater ecosystems in many watersheds by the mid- to long-term across all assessed scenarios (*medium confidence*). Projected increases in direct flood damages are higher by 1.4 to 2 times at 2°C and 2.5 to 3.9 times at 3°C compared to 1.5°C global warming without adaptation (*medium confidence*). At global warming of 4°C, approximately 10% of the global land area is projected to face increases in both extreme high and low river flows in the same location, with implications for planning for all water use sectors (*medium confidence*). Challenges for water management will be exacerbated in the near, mid and long term, depending on the magnitude, rate and regional details of future climate change and will be particularly challenging for regions with constrained resources for water management (*high confidence*). (2.3, 4.4, 4.5, Box 4.2, Figure 4.20, 15.3, CCP5.3, CCB DISASTER, SROCC 2.3)

B.4.3 Climate change will increasingly put pressure on food production and access, especially in vulnerable regions, undermining food security and nutrition (*high confidence*). Increases in frequency, intensity and severity of droughts, floods and heatwaves, and continued sea level rise will increase risks to food security (*high confidence*) in vulnerable regions from moderate to high between 1.5°C and 2°C global warming level, with no or low levels of adaptation (*medium confidence*). At 2°C or higher global warming level in the mid-term, food security risks due to climate change will be more severe, leading to malnutrition and micro-nutrient deficiencies, concentrated in Sub-Saharan Africa, South Asia, Central and South America and Small Islands (*high confidence*). Global warming will progressively weaken soil health and ecosystem services such as pollination, increase pressure from pests and diseases, and reduce marine animal biomass, undermining food productivity in many regions on land and in the ocean (*medium confidence*). At 3°C or higher global warming level in the long term, areas exposed to climate-related hazards will expand substantially compared with 2°C or lower global warming level (*high confidence*), exacerbating regional disparity in food security risks (*high confidence*). (Figure SPM.3) (1.1, 3.3, 4.5, 5.2, 5.4, 5.5, 5.8, 5.9, 5.12, 7.3, 8.3, 9.11, 13.5, 15.3, 16.5, 16.6, CCB MOVING PLATE, CCB SLR)

33 Number of species assessed are in the tens of thousands globally.

34 The term 'very high risk of extinction' is used here consistently with the IUCN categories and criteria and equates with 'critically endangered'.

B.4.4 Climate change and related extreme events will significantly increase ill health and premature deaths from the near- to long-term *(high confidence)*. Globally, population exposure to heatwaves will continue to increase with additional warming, with strong geographical differences in heat-related mortality without additional adaptation *(very high confidence)*. Climate-sensitive food-borne, water-borne, and vector-borne disease risks are projected to increase under all levels of warming without additional adaptation *(high confidence)*. In particular, dengue risk will increase with longer seasons and a wider geographic distribution in Asia, Europe, Central and South America and sub-Saharan Africa, potentially putting additional billions of people at risk by the end of the century *(high confidence)*. Mental health challenges, including anxiety and stress, are expected to increase under further global warming in all assessed regions, particularly for children, adolescents, elderly, and those with underlying health conditions *(very high confidence)*. (9.5, 5.12, Box 5.10, 7.3, Figure 7.9, 8.4, 9.10, Figure 9.32, Figure 9.35, 10.4, Figure 10.11, 11.3, 12.3, Figure 12.5, Figure 12.6, 13.7, Figure 13.23, Figure 13.24, 14.5, 15.3, CCP6.2)

B.4.5 Climate change risks to cities, settlements and key infrastructure will rise rapidly in the mid- and long-term with further global warming, especially in places already exposed to high temperatures, along coastlines, or with high vulnerabilities *(high confidence)*. Globally, population change in low-lying cities and settlements will lead to approximately a billion people projected to be at risk from coastal-specific climate hazards in the mid-term under all scenarios, including in Small Islands *(high confidence)*. The population potentially exposed to a 100-year coastal flood is projected to increase by about 20% if global mean sea level rises by 0.15 m relative to 2020 levels; this exposed population doubles at a 0.75 m rise in mean sea level and triples at 1.4 m without population change and additional adaptation *(medium confidence)*. Sea level rise poses an existential threat for some Small Islands and some low-lying coasts *(medium confidence)*. By 2100 the value of global assets within the future 1-in-100 year coastal floodplains is projected to be between US$7.9 and US$12.7 trillion (2011 value) under RCP4.5, rising to between US$8.8 and US$14.2 trillion under RCP8.5 *(medium confidence)*. Costs for maintenance and reconstruction of urban infrastructure, including building, transportation, and energy will increase with global warming level *(medium confidence)*, the associated functional disruptions are projected to be substantial particularly for cities, settlements and infrastructure located on permafrost in cold regions and on coasts *(high confidence)*. (6.2, 9.9, 10.4, 13.6, 13.10, 15.3, 16.5, CCP2.1, CCP2.2, CCP5.3, CCP6.2, CCB SLR, SROCC 2.3, SROCC CCB9)

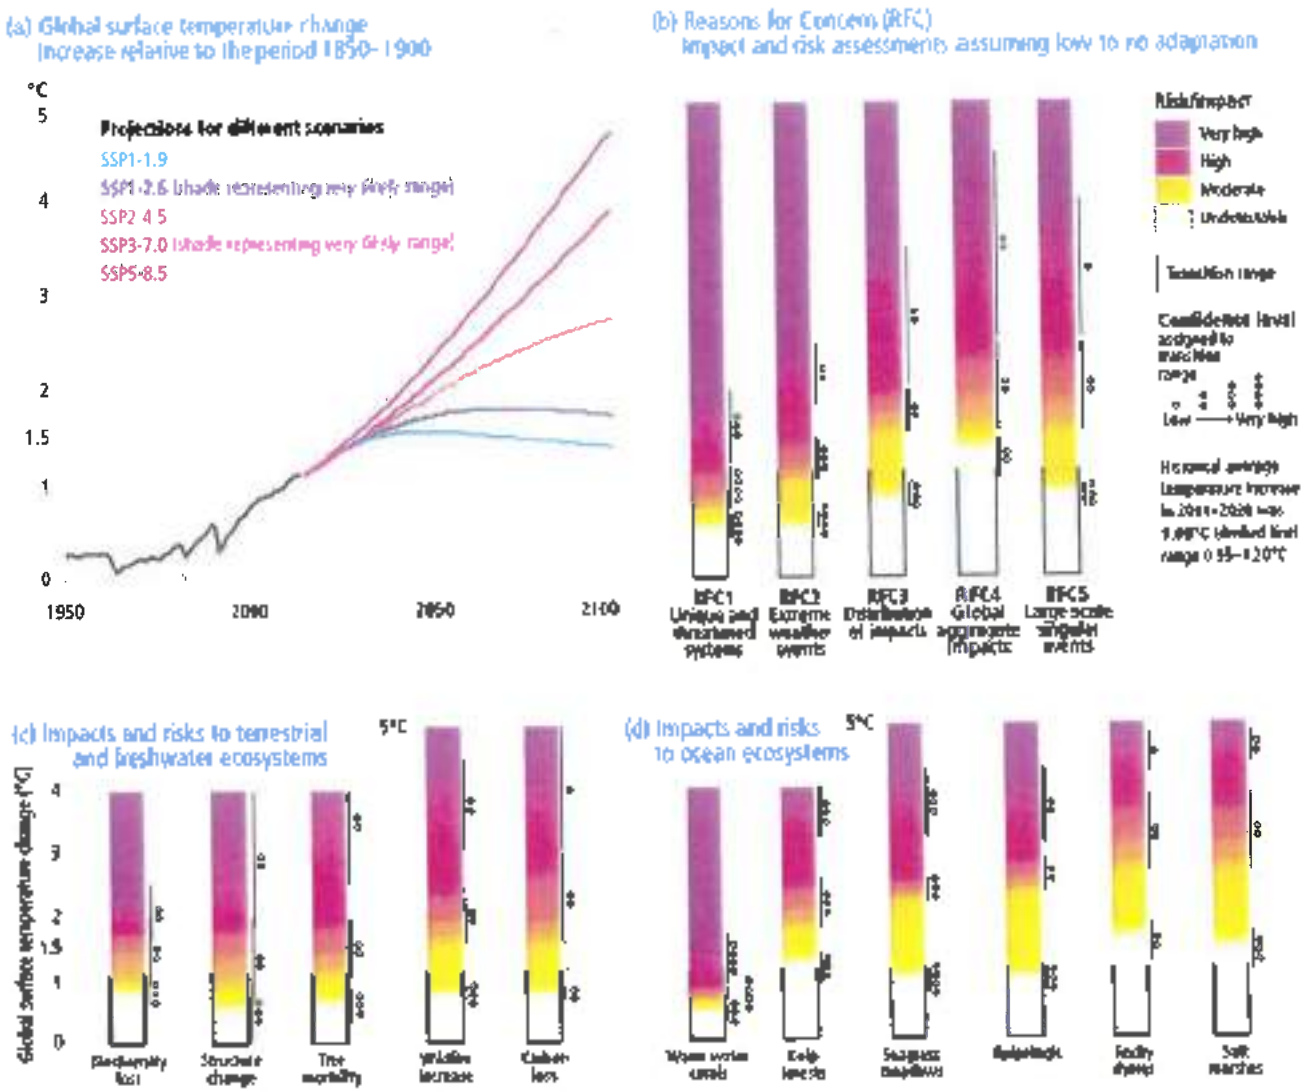
B.4.6 Projected estimates of global aggregate net economic damages generally increase non-linearly with global warming levels *(high confidence)*.[M] The wide range of global estimates, and the lack of comparability between methodologies, does not allow for identification of a robust range of estimates *(high confidence)*. The existence of higher estimates than assessed in AR5 indicates that global aggregate economic impacts could be higher than previous estimates *(low confidence)*.[M] Significant regional variation in aggregate economic damages from climate change is projected *(high confidence)* with estimated economic damages per capita for developing countries often higher as a fraction of income *(high confidence)*. Economic damages, including both those represented and those not represented in economic markets, are projected to be lower at 1.5°C than at 3°C or higher global warming levels *(high confidence)*. (8.4, 9.11, 11.5, 13.10, Box 14.6, 16.5, CWGB ECONOMIC)

B.4.7 In the mid- to long-term, displacement will increase with intensification of heavy precipitation and associated flooding, tropical cyclones, drought and, increasingly, sea level rise *(high confidence)*. At progressive levels of warming, involuntary migration from regions with high exposure and low adaptive capacity would occur *(medium confidence)*. Compared to other socioeconomic factors the influence of climate on conflict is assessed as relatively weak *(high confidence)*. Along long-term socioeconomic pathways that reduce non-climatic drivers, risk of violent conflict would decline *(medium confidence)*. At higher global warming levels, impacts of weather and climate extremes, particularly drought, by increasing vulnerability will increasingly affect violent intrastate conflict *(medium confidence)*. (TS B.7.4, 7.3, 16.5, CCB MIGRATE)

[M] The assessment found estimated rates of increase in projected global economic damages that were both greater than linear and less than linear as global warming level increases. There is evidence that some regions could benefit from low levels of warming *(high confidence)*. (CWGB ECONOMIC)

[M] *Low confidence* assigned due to the assessed lack of comparability and robustness of global aggregate economic damage estimates. (CWGB ECONOMIC)

Global and regional risks for increasing levels of global warming



* Mortality projections include demographic trends but do not include future effects on exposure or quality that influence ozone concentrations.

(f) Examples of regional key risks

Absence of risk diagrams does not imply absence of risks within a region. The development of synthetic diagrams for Small Islands, Asia and Central and South America was limited due to the paucity of adequately downscaled climate projections, with uncertainty in the direction of change, the diversity of climatologies and socioeconomic contexts across countries within a region, and the resulting low numbers of impact and risk projections for different warming levels.

The risks listed are of at least moderate confidence level

Small Islands
- Loss of terrestrial, marine and coastal biodiversity and ecosystem services
- Loss of lives and assets, risk to food security and economic disruptions due to destruction of settlements and infrastructure
- Economic decline and livelihood failure of fisheries, agriculture, tourism and from biodiversity loss from traditional agroecosystems
- Reduced habitability of rural and non-coastal islands leading to increased displacement
- Risk to water security in almost every small island

North America
- Climate-sensitive mental health outcomes, human mortality and morbidity due to increasing average temperature, weather and climate extremes, and compound climate hazards
- Risk of degradation of marine, coastal and terrestrial ecosystems, including loss of biodiversity, function, and provisioning services
- Risk to freshwater resources with consequences for ecosystems, reduced surface water availability for irrigated agriculture, other human uses, and degraded water quality
- Risk to food and nutritional security through changes in agriculture, livestock, farming, fisheries, and aquaculture productivity and access
- Risks to well-being, livelihoods and economic activities from cascading and compounding climate hazards, including risks to coastal cities, settlements and infrastructure from sea level rise

Europe
- Risks to people, economies and infrastructures due to coastal and inland flooding
- Stress and mortality to people due to increasing temperatures and heat extremes
- Marine and terrestrial ecosystems disruptions
- Water scarcity in multiple interconnected sectors
- Losses in crop production, due to compound heat and dry conditions, and extreme weather

Central and South America
- Risk to water security
- Severe health effects due to increasing epidemics, in particular vector-borne diseases
- Coral reef ecosystems degradation due to coral bleaching
- Risk to food security due to frequent/extreme droughts
- Damages to life and infrastructure due to floods, landslides, sea level rise, storm surges and coastal erosion

Australasia
- Degradation of tropical shallow coral reefs and associated biodiversity and ecosystem service values
- Loss of human and natural systems in low-lying coastal areas due to sea level rise
- Impact on livelihoods and incomes due to decline in agricultural production
- Increase in heat-related mortality and morbidity for people and wildlife
- Loss of alpine biodiversity in Australia due to less snow

Asia
- Urban infrastructure damage and impacts on human well-being and health due to flooding, especially in coastal cities and settlements
- Biodiversity loss and habitat shifts as well as associated disruptions in dependent human systems across freshwater, land, and ocean ecosystems
- More frequent, extensive coral bleaching and subsequent coral mortality induced by ocean warming and acidification, sea level rise, marine heat waves and resource extraction
- Decline in coastal fishery resources due to sea level rise, decrease in precipitation in some parts and increase in temperature
- Risk to food and water security due to increased temperature extremes, rainfall variability and drought

Africa
- Species extinction and reduction or irreversible loss of ecosystems and their services, including freshwater, land and ocean ecosystems
- Risk to food security, risk of malnutrition (micronutrient deficiency), and loss of livelihood due to reduced food production from crops, livestock and fisheries
- Risks to marine ecosystem health and to livelihoods in coastal communities
- Increased human mortality and morbidity due to increased heat and infectious diseases (including vector-borne and waterborne) diseases
- Reduced economic output and growth, and increased inequality and poverty rates
- Increased risk to water and energy security due to drought and heat

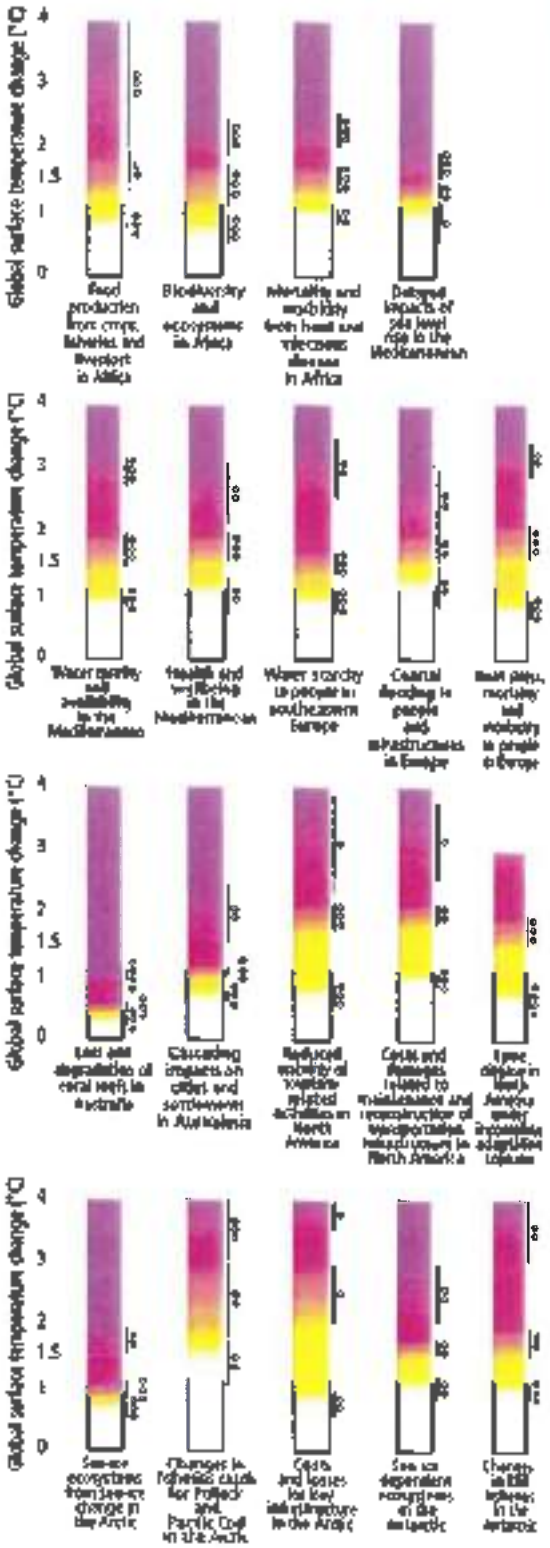


Figure SPM.3 | Synthetic diagrams of global and sectoral assessments and examples of regional key risks. Diagrams show the change in the levels of impacts and risks assessed for global warming of 0–5 °C global surface temperature change relative to pre-industrial period (1850–1900) over the range.

(a) Global surface temperature changes in °C relative to 1850–1900. These changes were obtained by combining CMIP6 model simulations with observational constraints based on past simulated warming, as well as an updated assessment of equilibrium climate sensitivity (Box SPM.1). Changes relative to 1850–1900 based on 20-year averaging periods are calculated by adding 0.85°C (the observed global surface temperature increase from 1850–1900 to 1995–2014) to simulated changes relative to 1995–2014. Very likely ranges are shown for SSP1-2.6 and SSP3-7.0 (WGI AR6 Figure SPM.8). Assessments were carried out on the global scale for (b1, b2), (c) and (d).

(b) The Reasons for Concern (RFC) framework communicates scientific understanding about accrual of risk for five broad categories. Diagrams are shown for each RFC, assuming low to no adaptation (i.e., adaptation is fragmented, localized and comprises incremental adjustments to existing practices). However, the transition to a very high risk level has an emphasis on irreversibility and adaptation limits. Undetectable risk level (white) indicates no attributed impacts are detectable and attributable to climate change; moderate risk (yellow) indicates attributed impacts are both detectable and attributable to climate change with at least medium confidence, also accounting for the other specific criteria for key risks; high risk (red) indicates severe and widespread impacts that are judged to be high on one or more criteria for assessing key risks, and very high risk level (purple) indicates very high risk of severe impacts and the presence of significant irreversibility or the persistence of climate-related hazards, combined with limited ability to adapt due to the nature of the hazard or impacts/risks. The horizontal line denotes the present global warming of 1.09°C which is used to separate the observed, past impacts below the line from the future projected risks above it. RFC1: Unique and threatened systems: ecological and human systems that have restricted geographic ranges constrained by climate-related conditions and have high endemism or other distinctive properties. Examples include coral reefs, the Arctic and its indigenous Peoples, mountain glaciers and biodiversity hotspots. RFC2: Extreme weather events: risks/impacts to human health, livelihoods, assets and ecosystems from extreme weather events such as heatwaves, heavy rain, drought and associated wildfire, and coastal flooding. RFC3: Distribution of impacts: risks/impacts that disproportionately affect particular groups due to uneven distribution of physical climate-change hazards, exposure or vulnerability. RFC4: Global aggregate impacts: impacts to socio-ecological systems that can be aggregated globally into a single metric, such as monetary damages, thus affected species lost or ecosystem degradation at a global scale. RFC5: Large-scale singular events: relatively large, abrupt and sometimes irreversible changes in systems caused by global warming, such as ice sheet disintegration or thermohaline circulation slowing. Assessment methods are described in SM16.6 and are identical to AR5, but are enhanced by a structured approach to improve robustness and facilitate comparison between AR5 and AR6.

Risks for (c) terrestrial and freshwater ecosystems and (d) ocean ecosystems. For c) and d), diagrams shown for each risk assume low to no adaptation. The transition to a very high risk level has an emphasis on irreversibility and adaptation limits.

(e) Climate-sensitive human health outcomes under three scenarios of adaptation effectiveness. The assessed projections were based on a range of scenarios, including SRES, CMIP5, and ISIMIP, and, in some cases, demographic trends. The diagrams are truncated at the nearest whole °C within the range of temperature change in 2100 under those SSP scenarios in panel (b).

(f) Examples of regional key risks. Risks identified are of at least medium confidence level. Key risks are identified based on the magnitude of adverse consequences (pervasiveness of the consequences, degree of change, irreversibility of consequences, potential for impact thresholds or tipping points, potential for cascading effects beyond system boundaries); likelihood of adverse consequences; temporal characteristics of the risk; and ability to respond to the risk, e.g., by adaptation. The full set of 127 assessed global and regional key risks is given in SM16.7. Diagrams are provided for some risks. The development of synthetic diagrams for Small Islands, Asia and Central and South America were limited by the availability of adequately downscaled climate projections, with uncertainty in the direction of change, the diversity of climatologies and socioeconomic contexts across countries within a region, and the resulting low number of impact and risk projections for different warming levels. Absence of risks depicted does not imply absence of risks within a region. (Box SPM.1) (Figure TS.4, Figure 2.11, Figure SM2.1, Figure 7.9, Figure 9.6, Figure 11.4, Figure 13.28, 16.5, 16.6, Figure 16.15, SM16.3, SM16.4, SM16.5, SM16.6 (methodologies), SM16.7, Figure CCP4.9, Figure CCP4.10, Figure CCP6.5, WGI AR6 2, WGI AR6 SPM A.1.2, WGI AR6 Figure SPM.8)

Complex, Compound and Cascading Risks

B.5 **Climate change impacts and risks are becoming increasingly complex and more difficult to manage. Multiple climate hazards will occur simultaneously, and multiple climatic and non-climatic risks will interact, resulting in compounding overall risk and risks cascading across sectors and regions. Some responses to climate change result in new impacts and risks. (*high confidence*)** {1.3, 2.4, Box 2.2, Box 9.5, 11.5, 13.5, 14.6, Box 15.1, CCP1.2, CCP2.2, CCB COVID, CCB DISASTER, CCB INTERACT, CCB SAND, }

B.5.1 Concurrent and repeated climate hazards occur in all regions. Increasing impacts and risks to health, ecosystems, infrastructure, livelihoods and food (*high confidence*). Multiple risks interact, generating new sources of vulnerability to climate hazards, and compounding overall risk (*high confidence*). Increasing concurrence of heat and drought events are causing crop production losses and tree mortality (*high confidence*). Above 1.5°C global warming increasing concurrent climate extremes will increase risk of simultaneous crop losses of maize in major food-producing regions, with this risk increasing further with higher global warming levels (*medium confidence*). Future sea level rise combined with storm surge and heavy rainfall will increase compound flood risks (*high confidence*). Risks to health and food production will be made more severe from the interaction of sudden food production losses from heat and drought, exacerbated by heat-induced labour productivity losses (*high confidence*). These interacting impacts will increase food prices, reduce household incomes, and lead to health risks of malnutrition and climate-related mortality with no or low levels of adaptation, especially in tropical regions (*high confidence*). Risks to food safety from climate change will further compound the risks to health by increasing food contamination of crops from mycotoxins and contamination of seafood from harmful algal blooms, mycotoxins, and chemical contaminants (*high confidence*). (Figure TS.10c, 5.2, 5.4, 5.8, 5.9, 5.11, 5.12, 7.2, 7.3, 9.8, 9.11, 10.4, 11.3, 11.5, 12.3, 13.5, 14.5, 15.3, Box 15.1, 16.6, CCP1.2, CCP6.2, , WGI AR6 SPM A.3.1, WGI AR6 SPM A.3.2, WGI AR6 SPM C.2.7)

B.5.2 Adverse impacts from climate hazards and resulting risks are cascading across sectors and regions (*high confidence*), propagating impacts along coasts and urban centres (*medium confidence*) and in mountain regions (*high confidence*). These hazards and cascading risks also trigger tipping points in sensitive ecosystems and in significantly and rapidly changing social-ecological systems impacted by ice melt, permafrost thaw and changing hydrology in polar regions (*high confidence*). Wildfires, in many regions, have affected ecosystems and species, people and their built assets, economic activity, and health (*medium to high confidence*). In cities and

settlements, climate impacts to key infrastructure are leading to losses and damages across water and food systems, and affect economic activity, with impacts extending beyond the area directly impacted by the climate hazard (*high confidence*). In Amazonia, and in some mountain regions, cascading impacts from climatic (e.g., heat) and non-climatic stressors (e.g., land use change) will result in irreversible and severe losses of ecosystem services and biodiversity at 2°C global warming level and beyond (*medium confidence*). Unavoidable sea level rise will bring cascading and compounding impacts resulting in losses of coastal ecosystems and ecosystem services, groundwater salinisation, flooding and damages to coastal infrastructure that cascade into risks to livelihoods, settlements, health, well-being, food and water security, and cultural values in the near to long-term (*high confidence*). (Figure SPM.3) (Figure TS.10, 2.5, 3.4, 3.5, Box 7.3, Box 8.7, Box 9.4, 11.5, Box 11.1, 12.3, 13.9, 14.6, 15.9, 16.5, 16.6, CCP1.2, CCP2.2, CCP5.2, CCP5.3, CCP6.2, CCP6.3, Box CCP6.1, Box CCP6.2, CCB EXTREMES, WGI AR6 Figure SPM.8d)

B.5.3 Weather and climate extremes are causing economic and societal impacts across national boundaries through supply-chains, markets, and natural resource flows, with increasing transboundary risks projected across the water, energy and food sectors (*high confidence*). Supply chains that rely on specialized commodities and key infrastructure can be disrupted by weather and climate extreme events. Climate change causes the redistribution of marine fish stocks, increasing risk of transboundary management conflicts among fisheries users, and negatively affecting equitable distribution of food provisioning services as fish stocks shift from lower to higher latitude regions, thereby increasing the need for climate-informed transboundary management and cooperation (*high confidence*). Precipitation and water availability changes increases the risk of planned infrastructure projects, such as hydropower in some regions, having reduced productivity for food and energy sectors including across countries that share river basins (*medium confidence*). (Figure TS.10e-f, 3.4, 3.5, 4.5, 5.8, 5.13, 6.2, 9.4, Box 9.5, 14.5, Box 14.5, Box 14.6, CCP5.3, CCB DISASTER, CCB EXTREMES, CCB INTERES, CCB MOVING PLATE)

B.5.4 Risks arise from some responses that are intended to reduce the risks of climate change, including risks from maladaptation and adverse side effects of some emissions reduction and carbon dioxide removal measures (*high confidence*). Deployment of afforestation of naturally unforested land, or poorly implemented bioenergy, with or without carbon capture and storage, can compound climate-related risks to biodiversity, water and food security, and livelihoods, especially if implemented at large scales, especially in regions with insecure land tenure (*high confidence*). (Box 2.2, 4.1, 4.7, 5.13, Table 5.18, Box 9.3, Box 13.2, CCB NATURAL, CWGB BIOECONOMY)

B.5.5 Solar radiation modification approaches, if they were to be implemented, introduce a widespread range of new risks to people and ecosystems, which are not well understood (*high confidence*). Solar radiation modification approaches have potential to offset warming and ameliorate some climate hazards, but substantial residual climate change or overcompensating change would occur at regional scales and seasonal timescales (*high confidence*). Large uncertainties and knowledge gaps are associated with the potential of solar radiation modification approaches to reduce climate change risks. Solar radiation modification would not stop atmospheric CO_2 concentrations from increasing or reduce resulting ocean acidification under continued anthropogenic emissions (*high confidence*). (CWGB SRM)

Impacts of Temporary Overshoot

B.6 If global warming transiently exceeds 1.5°C in the coming decades or later (overshoot)[17], then many human and natural systems will face additional severe risks, compared to remaining below 1.5°C (*high confidence*). Depending on the magnitude and duration of overshoot, some impacts will cause release of additional greenhouse gases (*medium confidence*) and some will be irreversible, even if global warming is reduced (*high confidence*). (Box SPM.1, Figure SPM.3) (2.5, 3.4, 12.3, 16.6, CCB DEEP, CCB SLR)

B.6.1 While model-based assessments of the impacts of overshoot pathways are limited, observations and current understanding of processes permit assessment of impacts from overshoot. Additional warming, e.g., above 1.5°C during an overshoot period this century, will result in irreversible impacts on certain ecosystems with low resilience, such as polar, mountain, and coastal ecosystems, impacted by ice-sheet, glacier melt, or by accelerating and higher committed sea level rise (*high confidence*).[18] Risks to human systems will increase, including those to infrastructure, low-lying coastal settlements, some ecosystem-based adaptation measures, and associated livelihoods (*high confidence*), cultural and spiritual values (*medium confidence*). Projected impacts are less severe with shorter duration and lower levels of overshoot (*medium confidence*). (2.5, 3.4, 12.3, 13.2, 16.5, 16.6, CCP1.2, CCP2.2, CCP5.3, CCP6.1, CCP6.2, CCB SLR, WGI AR6 SPM B.5, WGII AR6 SPM C.3, SROCC 2.3, SROCC 5.4)

---

17 In this report, overshoot pathways exceed 1.5°C global warming and then return to that level, or below, after several decades.

18 Despite limited evidence specifically on the impacts of a temporary overshoot of 1.5°C, a much broader evidence base from process understanding and the impacts of higher global warming levels allows a high confidence statement on the irreversibility of some impacts that would be incurred following such an overshoot.

B.6.2 Risk of severe impacts increase with every additional increment of global warming during overshoot *(high confidence)*. In high-carbon ecosystems (currently storing 3,000 to 4,000 GtC)[39] such impacts are already observed and are projected to increase with every additional increment of global warming, such as increased wildfires, mass mortality of trees, drying of peatlands, and thawing of permafrost, weakening natural land carbon sinks and increasing releases of greenhouse gases *(medium confidence)*. The resulting contribution to a potential amplification of global warming indicates that a return to a given global warming level or below would be more challenging *(medium confidence)*. (2.4, 2.5, CCP4.2, IGI ARS SPM B.4.3, SROCC 5.4)

C: Adaptation Measures and Enabling Conditions

Adaptation, in response to current climate change, is reducing climate risks and vulnerability mostly via adjustment of existing systems. Many adaptation options exist and are used to help manage projected climate change impacts, but their implementation depends upon the capacity and effectiveness of governance and decision-making processes. These and other enabling conditions can also support climate resilient development (Section D).

Current Adaptation and Its Benefits

C.1 Progress in adaptation planning and implementation has been observed across all sectors and regions, generating multiple benefits *(very high confidence)*. However, adaptation progress is unevenly distributed with observed adaptation gaps[40] *(high confidence)*. Many initiatives prioritize immediate and near-term climate risk reduction which reduces the opportunity for transformational adaptation *(high confidence)*. (2.6, 5.14, 7.4, 10.4, 12.5, 13.11, 14.7, 16.3, 17.3, CCP5.2, CCP5.4)

C.1.1 Adaptation planning and implementation have continued to increase across all regions *(very high confidence)*. Growing public and political awareness of climate impacts and risks has resulted in at least 170 countries and many cities including adaptation in their climate policies and planning processes *(high confidence)*. Decision support tools and climate services are increasingly being used *(very high confidence)*. Pilot projects and local experiments are being implemented in different sectors *(high confidence)*. Adaptation can generate multiple additional benefits such as improving agricultural productivity, innovation, health and well-being, food security, livelihood, and biodiversity conservation as well as reduction of risks and damages *(very high confidence)*. (1.4, 2.6, 3.5, 3.6, 4.7, 4.8, 5.4, 5.6, 5.10, 6.4, 7.4, 8.5, 9.3, 9.6, 10.4, 12.5, 13.11, 15.5, 16.3, 17.2, 17.3, 17.5, CCP5.4, CCB ADAPT, CCB NATURAL)

C.1.2 Despite progress, adaptation gaps exist between current levels of adaptation and levels needed to respond to impacts and reduce climate risks *(high confidence)*. Most observed adaptation is fragmented, small in scale, incremental, sector-specific, designed to respond to current impacts or near-term risks, and focused more on planning rather than implementation *(high confidence)*. Observed adaptation is unequally distributed across regions *(high confidence)*, and gaps are partially driven by widening disparities between the estimated costs of adaptation and documented finance allocated to adaptation *(high confidence)*. The largest adaptation gaps exist among lower income population groups *(high confidence)*. At current rates of adaptation planning and implementation the adaptation gap will continue to grow *(high confidence)*. As adaptation options often have long implementation times, long-term planning and accelerated implementation, particularly in the near decade, is important to close adaptation gaps, recognising that constraints remain for some regions *(high confidence)*. (1.1, 1.4, 5.6, 8.3, Figure 8.4, 7.4, 8.5, 10.4, 11.3, 11.7, 13.11, Box 13.1, 15.2, 15.5, 16.3, 16.5, Box 16.1, Figure 16.4, Figure 16.5, 17.4, 18.2, CCP2.4, CCP5.4, CCB FINANCE, CCB SLR)

[39] At the global scale, terrestrial ecosystems currently remove more carbon from the atmosphere (3.4 ± 0.9 Gt yr⁻¹ than they emit (+1.6 ± 0.7 Gt yr⁻¹), a net sink of −1.8 ± 1.1 Gt yr⁻¹. However, recent climate change has shifted some systems to some regions from being net carbon sinks to net carbon sources.

[40] Adaptation gaps are defined as the difference between actually implemented adaptation and a societally set goal, as measured largely by preferences related to historical climate change impacts and reflecting resource limitations and competing priorities.

Future Adaptation Options and their Feasibility

C.2 **There are feasible[41] and effective[42] adaptation options which can reduce risks to people and nature. The feasibility of implementing adaptation options in the near-term differs across sectors and regions *(very high confidence)*. The effectiveness of adaptation to reduce climate risk is documented for specific contexts, sectors and regions *(high confidence)* and will decrease with increasing warming *(high confidence)*. Integrated, multi-sectoral solutions that address social inequities, differentiate responses based on climate risk and cut across systems, increase the feasibility and effectiveness of adaptation in multiple sectors *(high confidence)*. (Figure SPM.4) (Figure TS.6a, 1.4, 3.6, 4.7, 5.12, 6.3, 7.4, 11.3, 11.7, 13.2, 15.5, 17.6, CCP2.3, CCB FEASIB)**

Land, Ocean and Ecosystem Transition

C.2.1 **Adaptation to water-related risks and impacts make up the majority of all documented adaptation *(high confidence)*. For inland flooding, combinations of non-structural measures like early warning systems and structural measures like levees have reduced loss of lives *(medium confidence)*. Enhancing natural water retention such as by restoring wetlands and rivers, land use planning such as no build zones or upstream forest management, can further reduce flood risk *(medium confidence)*. On-farm water management, water storage, soil moisture conservation and irrigation are some of the most common adaptation responses and provide economic, institutional or ecological benefits and reduce vulnerability *(high confidence)*. Irrigation is effective in reducing drought risk and climate impacts in many regions and has several livelihood benefits, but needs appropriate management to avoid potential adverse outcomes, which can include accelerated depletion of groundwater and other water sources and increased soil salinization *(medium confidence)*. Large scale irrigation can also alter local to regional temperature and precipitation patterns *(high confidence)*, including both alleviating and exacerbating temperature extremes *(medium confidence)*. The effectiveness of most water-related adaptation options to reduce projected risks declines with increasing warming *(high confidence)*. (4.1, 4.6, 4.7, Box 4.3, Box 4.6, Box 4.7, Figure 4.22, Figure 4.28, Figure 4.29, Table 4.9, 9.3, 9.7, 11.3, 12.5, 13.1, 13.2, 16.3, CCP5.4)**

C.2.2 **Effective adaptation options, together with supportive public policies enhance food availability and stability and reduce climate risk for food systems while increasing their sustainability *(medium confidence)*. Effective options include cultivar improvements, agroforestry, community-based adaptation, farm and landscape diversification, and urban agriculture *(high confidence)*. Institutional feasibility, adaptation limits of crops and cost effectiveness also influence the effectiveness of the adaptation options *(limited evidence, medium agreement)*. Agroecological principles and practices, ecosystem-based management in fisheries and aquaculture, and other approaches that work with natural processes support food security, nutrition, health and well-being, livelihoods and biodiversity, sustainability and ecosystem services *(high confidence)*. These services include pest control, pollination, buffering of temperature extremes, and carbon sequestration and storage *(high confidence)*. Trade-offs and barriers associated with such approaches include costs of establishment, access to inputs and viable markets, new knowledge and management *(high confidence)* and their potential effectiveness varies by socioeconomic context, ecosystem zone, species combinations and institutional support *(medium confidence)*. Integrated, multi-sectoral solutions that address social inequities and differentiate responses based on climate risk and local situation will enhance food security and nutrition *(high confidence)*. Adaptation strategies which reduce food loss and waste or support balanced diets[43] (as described in the IPCC Special Report on Climate Change and Land) contribute to nutrition, health, biodiversity and other environmental benefits *(high confidence)*. (3.2, 4.7, 4.6, Box 4.3, 5.4, 5.5, 5.6, 5.8, 5.9, 5.10, 5.11, 5.12, 5.13, 5.14, Box 5.10, Box 5.13, 6.3, 7.4, 10.4, 12.5, 13.5, 13.10, 14.5, CCP5.4, CCB FEASIB, CCB HEALTH, CCB MOVING PLATE, CCB NATURAL, CWGB BIOECONOMY)**

C.2.3 **Adaptation for natural forests[44] includes conservation, protection and restoration measures. In managed forests[45], adaptation options include sustainable forest management, diversifying and adjusting tree species compositions to build resilience, and managing increased risks from pests and diseases and wildfires. Restoring natural forests and drained peatlands and improving sustainability of managed forests, generally enhances the resilience of carbon stocks and sinks. Cooperation, and inclusive decision making, with local communities and Indigenous Peoples, as well as recognition of inherent rights of Indigenous Peoples, is integral to successful forest adaptation in many areas. (high confidence) (2.6, Box 2.2, 5.6, 5.13, Table 5.23, 11.4, 12.5, 13.5, Box 14.1, Box 14.2, CCP7.5, Box CCP7.1, CCB FEASIB, CCB RKDG, CCB NATURAL)**

---

41 In this report, feasibility refers to the potential for a mitigation or adaptation option to be implemented. Factors influencing feasibility are context-dependent, temporally dynamic, and may vary between different groups and actors. Feasibility depends on geophysical, environmental-ecological, technological, economic, socio-cultural, and institutional factors that enable or constrain the implementation of an option. The feasibility of options may change when different options are combined and increases when enabling conditions are strengthened.

42 Effectiveness refers to the extent to which an adaptation option is anticipated or observed to reduce climate-related risk.

43 In this report, the term natural forests describes those which are subject to little or no direct human intervention, whereas the term managed forests describes those where planting or other management activities take place, including those managed for commodity production.

(a) Diverse feasible climate responses and adaptation options exist to respond to Representative Key Risks of climate change, with varying synergies with mitigation

Multidimensional feasibility and synergies with mitigation of climate responses and adaptation options relevant in the near-term, at global scale and up to 1.5°C of global warming

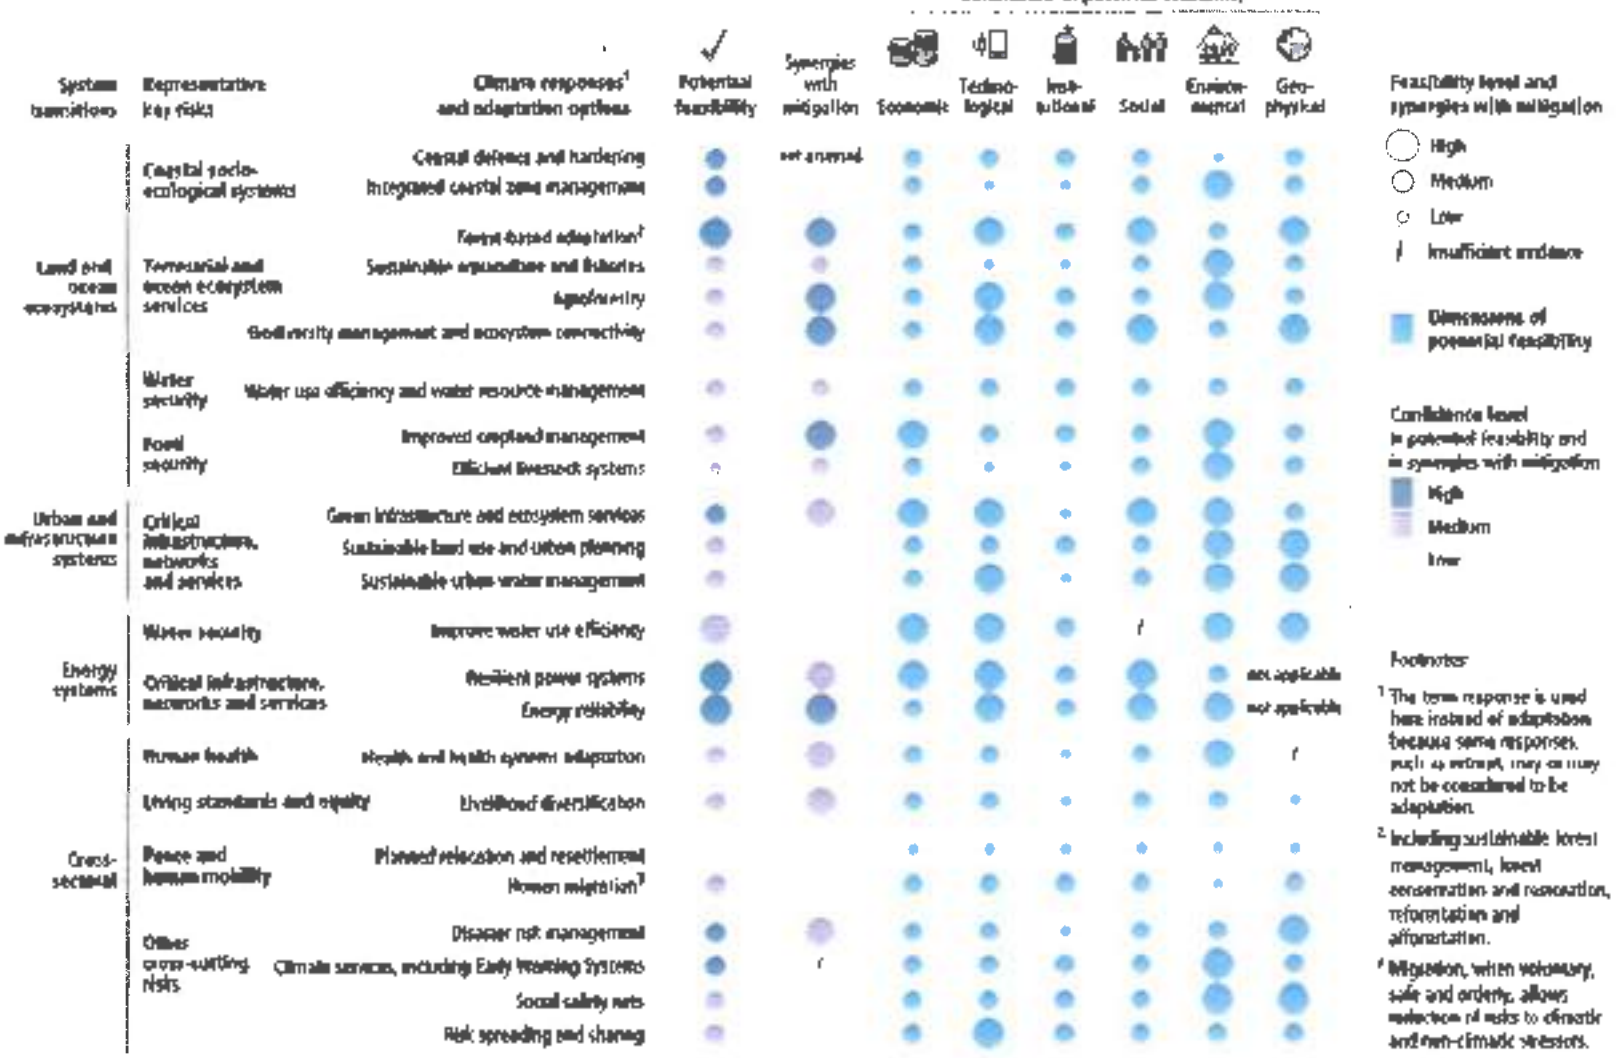

Figure SPM.8 | (a) Climate responses and adaptation options, organized by System Transitions and Representative Key Risks (RKRs), are assessed for their multidimensional feasibility at global scale, in the near-term and up to 1.5°C global warming. As literature above 1.5°C is limited, feasibility at higher levels of warming may change, which is currently not possible to assess robustly. Climate responses and adaptation options at global scale are drawn from a set of options assessed in AR6 that have robust evidence across the feasibility dimensions. This figure shows the six feasibility dimensions (economic, technological, institutional, social, environmental and geophysical) that are used to calculate the potential feasibility of climate responses and adaptation options, along with their synergies with mitigation. For potential feasibility and feasibility dimensions, the figure shows high, medium, or low feasibility. Synergies with mitigation are classified as high, medium, and low. Insufficient evidence is denoted by a dash. [CCB WGIII AR6, Table SM.CCB.6(A+B).1.1, SR1.5 4.5(SM.4.2)]

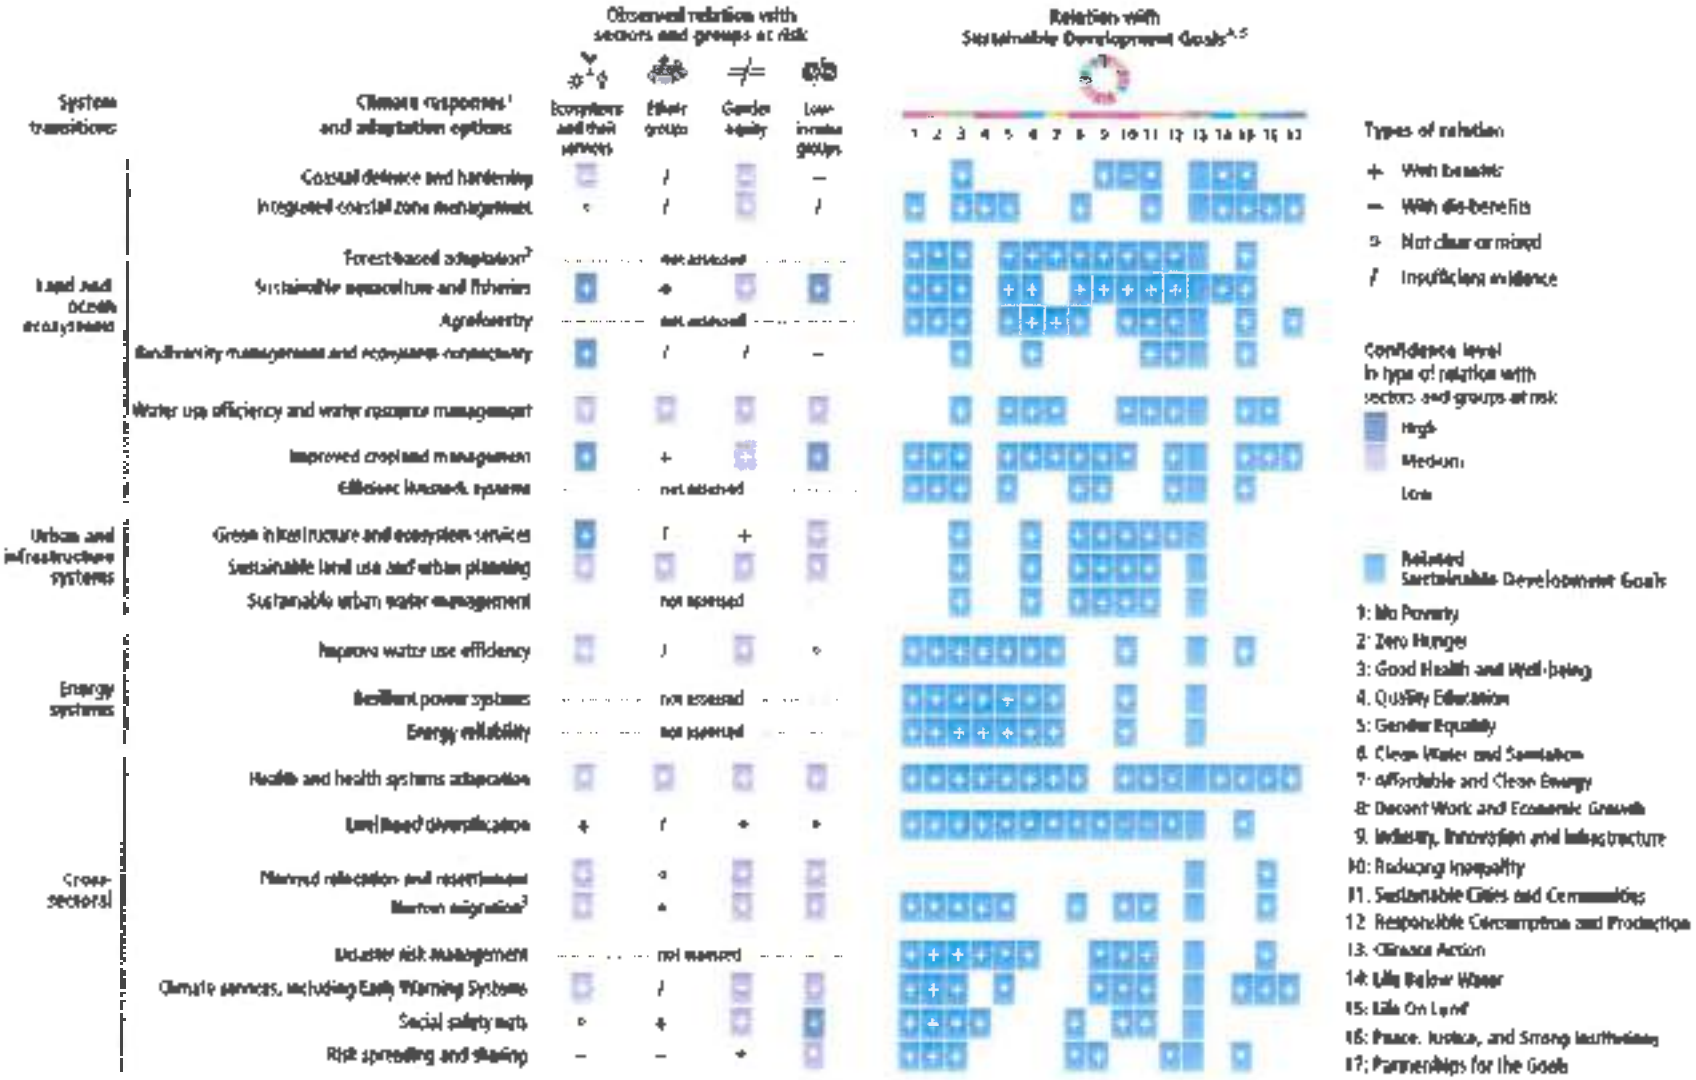
(b) Climate responses and adaptation options have benefits for ecosystems, ethnic groups, gender equity, low-income groups and the Sustainable Development Goals

Relations of sectors and groups at risk (as observed) and the SDGs (relevant in the near-term, at global scale and up to 1.5°C of global warming) with climate responses and adaptation options



Footnotes: [1] The same response is used here instead of adaptation because some responses, such as retreat, may or may not be considered to be adaptation. [2] Including sustainable forest management, forest conservation and restoration, reforestation and afforestation. [3] Migration, when voluntary, safe and orderly, allows reduction of risks to climate and non-climate stressors. [4] The Sustainable Development Goals (SDGs) are integrated and indivisible, and efforts to achieve any goal in isolation may trigger synergies or trade-offs with other SDGs. [5] Relevant in the near-term, at global scale and up to 1.5°C of global warming.

Figure SPM.4 | (b) Climate responses and adaptation options, organized by System Transitions and Representative Key Risks, are assessed at global scale for their likely ability to reduce risks for ecosystems and social groups at risk, as well as their relation with the 17 Sustainable Development Goals (SDGs). Climate responses and adaptation options are assessed for observed benefits (+) to ecosystems and their services, ethnic groups, gender equity, and low-income groups, or observed dis-benefits (-) for these systems and groups. Where there is highly diverging evidence of benefits/ dis-benefits across the scientific literature, e.g., based on differences between regions, it is shown as not clear or mixed (+). Insufficient evidence is shown by a dash. The relation with the SDGs is assessed as having benefits (+), dis-benefits (-) or not clear or mixed (+) based on the impacts of the climate response and adaptation option on each SDG. Areas not coloured indicate there is no evidence of a relation or no interaction with the respective SDG. The climate responses and adaptation options are drawn from two assessments. For compatibility of climate responses and adaptation options see Table SM17.5. [17.2, 17.5, CCB FEASIB]

C.2.4 Conservation, protection and restoration of terrestrial, freshwater, coastal and ocean ecosystems, together with targeted management to adapt to unavoidable impacts of climate change, reduces the vulnerability of biodiversity to climate change (*high confidence*). The resilience of species, biological communities and ecosystem processes increases with size of natural area, by restoration of degraded areas and by reducing non-climatic stressors (*high confidence*). To be effective, conservation and restoration actions will increasingly need to be responsive, as appropriate, to ongoing changes at various scales, and plan for future changes in ecosystem structure, community composition and species' distributions, especially as 1.5°C global warming is approached and even more so if it is exceeded (*high confidence*). Adaptation options, where circumstances allow, include facilitating the movement of species to new ecologically appropriate locations, particularly through increasing connectivity between conserved or protected areas, targeted intensive management for vulnerable species and protecting refugial areas where species can survive locally (*medium confidence*). [2.3, 2.6, Figure 2.1, Table 2.6, 3.3, 3.6, Box 3.4, 4.6, Box 4.6, Box 11.2, 12.3, 12.5, 13.4, 14.7, CCP5.4, CCB FEASIB]

C.2.5 Effective Ecosystem-based Adaptation[44] reduces a range of climate change risks to people, biodiversity and ecosystem services with multiple co-benefits (*high confidence*). Ecosystem-based Adaptation is vulnerable to climate change impacts, with effectiveness declining with increasing global warming (*high confidence*). Urban greening using trees and other vegetation can provide local cooling (*very high confidence*). Natural river systems, wetlands and upstream forest ecosystems reduce flood risk by storing water and slowing water flows, in most circumstances (*high confidence*). Coastal wetlands protect against coastal erosion and flooding associated with storms and sea level rise where sufficient space and adequate habitats are available until rates of sea level rise exceeds natural adaptive capacity to build sediment (*very high confidence*). [2.4, 2.5, 2.6, Table 2.7, 3.4, 3.5, 3.6, Figure 3.26, 4.6, Box 4.8, Box 4.7, 5.5, 5.14, Box 5.11, 6.3, 6.4, Figure 6.6, 7.4, 8.5, 8.6, 9.6, 9.8, 9.9, 10.2, 11.3, 12.5, 13.3, 13.4, 13.5, 14.5, Box 14.7, 16.3, 18.3, CCP5.4, CCB FEASIB.3, CCB HEALTH, CCB MOVING PLATE, CCB NATURAL, CWGB BIOECONOMY]

Urban, Rural and Infrastructure Transition

C.2.6 Considering climate change impacts and risks in the design and planning of urban and rural settlements and infrastructure is critical for resilience and enhancing human well-being (*high confidence*). The urgent provision of basic services, infrastructure, livelihood diversification and employment, strengthening of local and regional food systems and community-based adaptation enhance lives and livelihoods, particularly of low-income and marginalised groups (*high confidence*). Inclusive, integrated and long-term planning at local, municipal, sub-national and national scales, together with effective regulation and monitoring systems and financial and technological resources and capabilities foster urban and rural system transition (*high confidence*). Effective partnerships between governments, civil society, and private sector organizations, across scales provide infrastructure and services in ways that enhance the adaptive capacity of vulnerable people (*medium to high confidence*). [5.12, 5.13, 5.14, 6.3, 6.4, Box 6.3, Box 6.6, Table 6.6, 7.4, 12.5, 13.6, 14.5, Box 16.4, Box 17.4, CCP2.3, CCP2.4, CCP5.4, CCB FEASIB]

C.2.7 An increasing number of adaptation responses exist for urban systems, but their feasibility and effectiveness is constrained by institutional, financial, and technological access and capacity, and depends on coordinated and contextually appropriate responses across physical, natural and social infrastructure (*high confidence*). Globally, more financing is directed at physical infrastructure than natural and social infrastructure (*medium confidence*) and there is *limited* evidence of investment in the informal settlements hosting the most vulnerable urban residents (*medium to high confidence*). Ecosystem-based adaptation (e.g., urban agriculture and forestry, river restoration) has increasingly been applied in urban areas (*high confidence*). Combined ecosystem-based and structural adaptation responses are being developed, and there is growing evidence of their potential to reduce adaptation costs and contribute to flood control, sanitation, water resources management, landslide prevention and coastal protection (*medium confidence*). [3.6, Box 4.6, 5.12, 6.3, 6.4, Table 6.8, 7.4, 9.7, 9.9, 10.4, Table 10.3, 11.3, 11.7, Box 11.6, 12.5, 13.2, 13.3, 13.6, 14.5, 15.5, 17.2, Box 17.4, CCP2.3, CCP 3.2, CCP5.4, CCB FEASIB, CCB SLR, SROCC SPM]

[44] Ecosystem based Adaptation (EbA) is recognized internationally under the Convention on Biological Diversity (CBD 14/5). A related concept is nature-based solutions (NbS), which includes a broader range of approaches with safeguards, including those that contribute to adaptation and mitigation. The term 'nature-based solutions' is widely but not universally used in the scientific literature. The term is the subject of ongoing debate, with concerns that it may lead to the misunderstanding that NbS on its own can provide a global solution to climate change.

C.2.8 Sea level rise poses a distinctive and severe adaptation challenge as it implies dealing with slow onset changes and increased frequency and magnitude of extreme sea level events which will escalate in the coming decades (*high confidence*). Such adaptation challenges would occur much earlier under high rates of sea level rise, in particular if low-likelihood, high impact outcomes associated with collapsing ice sheets occur (*high confidence*). Responses[45] to ongoing sea level rise and land subsidence in low-lying coastal cities and settlements and small islands include protection, accommodation, advance and planned relocation (*high confidence*)[46]. These responses are more effective if combined and/or sequenced, planned well ahead, aligned with socio-cultural values and development priorities, and underpinned by inclusive community engagement processes (*high confidence*). {6.2, 10.4, 11.7, Box 11.6, 13.2, 14.5, 15.5, CCP2.3, CCB SLR, WGI AR6 SPM B.5, WGI AR6 SPM C.3, SROCC SPM C3.2}

C.2.9 Approximately 3.4 billion people globally live in rural areas around the world, and many are highly vulnerable to climate change. Integrating climate adaptation into social protection programs, including cash transfers and public works programmes, is highly feasible and increases resilience to climate change, especially when supported by basic services and infrastructure. Social safety nets are increasingly being reconfigured to build adaptive capacities of the most vulnerable in rural and also urban communities. Social safety nets that support climate change adaptation have strong co-benefits with development goals such as education, poverty alleviation, gender inclusion and food security. (*high confidence*) {5.14, 9.4, 9.10, 9.11, 12.5, 14.5, CCP5.4, CCB FEASIB, CCB GENDER}

Energy System Transition

C.2.10 Within energy system transitions, the most feasible adaptation options support infrastructure resilience, reliable power systems and efficient water use for existing and new energy generation systems (*very high confidence*). Energy generation diversification, including with renewable energy resources and generation that can be decentralised depending on context (e.g., wind, solar, small scale hydroelectric) and demand side management (e.g., storage, and energy efficiency improvements) can reduce vulnerabilities to climate change, especially in rural populations (*high confidence*). Adaptations for hydropower and thermo-electric power generation are effective in most regions up to 1.5°C to 2°C, with decreasing effectiveness at higher levels of warming (*medium confidence*). Climate responsive energy markets, updated design standards on energy assets according to current and projected climate change, smart-grid technologies, robust transmission systems and improved capacity to respond to supply deficits have high feasibility in the medium- to long-term, with mitigation co-benefits (*very high confidence*). {4.6, 4.7, Figure 4.28, Figure 4.29, 10.4, Table 11.8, 13.6, Figure 13.16, Figure 13.19, 15.3, CCP5.2, CCP5.4, CCB FEASIB, CWGIII BIOECONOMY}

Cross-cutting Options

C.2.11 Strengthening the climate resiliency of health systems will protect and promote human health and well-being (*high confidence*). There are multiple opportunities for targeted investments and finance to protect against exposure to climate hazards, particularly for those at highest risk. Heat Health Action Plans that include early warning and response systems are effective adaptation options for extreme heat (*high confidence*). Effective adaptation options for water-borne and food-borne diseases include improving access to potable water, reducing exposure of water and sanitation systems to flooding and extreme weather events, and improved early warning systems (*very high confidence*). For vector-borne diseases, effective adaptation options include surveillance, early warning systems, and vaccine development (*very high confidence*). Effective adaptation options for reducing mental health risks under climate change include improving surveillance, access to mental health care, and monitoring of psychosocial impacts from extreme weather events (*high confidence*). Health and well-being would benefit from integrated adaptation approaches that mainstream health into food, livelihoods, social protection, infrastructure, water and sanitation policies requiring collaboration and coordination at all scales of governance (*very high confidence*). {5.12, 6.3, 7.4, 9.10, Box 9.7, 11.3, 12.5, 13.7, 14.5, CCB COVID, CCB FEASIB, CCB ILLNESS}

C.2.12 Increasing adaptive capacities minimises the negative impacts of climate-related displacement and involuntary migration for migrants and sending and receiving areas (*high confidence*). This improves the degree of choice under which migration decisions are made, ensuring safe and orderly movements of people within and between countries (*high confidence*). Some development reduces underlying vulnerabilities associated with conflict, and adaptation contributes by reducing the impacts of climate change on climate sensitive drivers of conflict (*high confidence*). Risks to peace are reduced, for example, by supporting people in climate-sensitive economic activities (*medium confidence*) and advancing women's empowerment (*high confidence*). {7.4, Box 9.8, Box 10.2, 12.5, CCB FEASIB, CCB MIGRATE}

45 The term 'response' is used here instead of adaptation because some responses, such as retreat, may or may not be considered to be adaptation.

C.2.13 There are a range of adaptation options, such as disaster risk management, early warning systems, climate services and risk spreading and sharing that have broad applicability across sectors and provide greater benefits to other adaptation options when combined (*high confidence*). For example, climate services that are inclusive of different users and providers can improve agricultural practices, inform better water use and efficiency, and enable resilient infrastructure planning (*high confidence*). (2.6, 3.6, 4.7, 5.4, 5.5, 5.6, 5.8, 5.9, 5.12, 5.14, 9.4, 9.8, 10.4, 12.5, 13.11, CCP5.4, CCB FEASIB, CCB MOVING PLATE)

Limits to Adaptation

C.3 Soft limits to some human adaptation have been reached, but can be overcome by addressing a range of constraints, primarily financial, governance, institutional and policy constraints (*high confidence*). Hard limits to adaptation have been reached in some ecosystems (*high confidence*). With increasing global warming, losses and damages will increase and additional human and natural systems will reach adaptation limits (*high confidence*). (Figure TS.7, 1.4, 2.6, 2.5, 2.6, 3.4, 3.6, 4.7, Figure 4.30, 5.5, Table 8.6, Box 10.7, 11.7, Table 11.16, 12.5, 13.2, 13.5, 13.6, 13.10, 13.11, Figure 13.21, 14.5, 15.6, 16.4, Figure 16.8, Table 16.9, Table 16.8, CCP1.2, CCP1.3, CCP2.3, CCP3.3, CCP5.2, CCP5.4, CCP6.3, CCP7.3, CCB SLR)

C.3.1 Soft limits to some human adaptation have been reached, but can be overcome by addressing a range of constraints, which primarily consist of financial, governance, institutional and policy constraints (*high confidence*). For example, individuals and households in low-lying coastal areas in Australasia and Small Islands and smallholder farmers in Central and South America, Africa, Europe and Asia have reached soft limits (*medium confidence*). Inequity and poverty also constrain adaptation, leading to soft limits and resulting in disproportionate exposure and impacts for most vulnerable groups (*high confidence*). Lack of climate literacy[46] at all levels and limited availability of information and data pose further constraints to adaptation planning and implementation (*medium confidence*). (1.4, 4.7, 5.4, 8.4, Table 8.6, 9.1, 9.4, 9.5, 9.8, 11.7, 12.5 13.5, 15.3, 15.5, 15.6, 16.4, Box 16.1, Figure 16.8, CCP5.2, CCP5.4, CCP6.3)

C.3.2 Financial constraints are important determinants of soft limits to adaptation across sectors and all regions (*high confidence*). Although global tracked climate finance has shown an upward trend since AR5, current global financial flows for adaptation, including from public and private finance sources, are insufficient for and constrain implementation of adaptation options especially in developing countries (*high confidence*). The overwhelming majority of global tracked climate finance was targeted to mitigation while a small proportion was targeted to adaptation (*very high confidence*). Adaptation finance has come predominantly from public sources (*very high confidence*). Adverse climate impacts can reduce the availability of financial resources by incurring losses and damages and through impeding national economic growth, thereby further increasing financial constraints for adaptation, particularly for developing and least developed countries (*medium confidence*). (Figure TS.7, 1.4, 2.6, 3.6, 4.7, Figure 4.30, 5.14, 7.4, 8.4, Table 8.6, 9.4, 9.9, 9.11, 10.5, 12.5, 13.3, 13.11, Box 14.4, 15.6, 16.2, 16.4, Figure 16.8, Table 16.4, 17.4, 18.1, CCP2.4, CCP5.4, CCP6.3, CCB FINANCE)

C.3.3 Many natural systems are near the hard limits of their natural adaptation capacity and additional systems will reach limits with increasing global warming (*high confidence*). Ecosystems already reaching or surpassing hard adaptation limits include some warm-water coral reefs, some coastal wetlands, some rainforests, and some polar and mountain ecosystems (*high confidence*). Above 1.5°C global warming level, some Ecosystem-based Adaptation measures will lose their effectiveness in providing benefits to people as these ecosystems will reach hard adaptation limits (*high confidence*). (Figure SPM.4) (1.4, 2.4, 2.6, 3.4, 3.6, 9.6, Box 13.2, 13.4, 14.5, 15.5, 16.4, 16.6, 17.2, CCP1.2, CCP5.2, CCP6.3, CCP7.3, CCB SLR)

C.3.4 In human systems, some coastal settlements face soft adaptation limits due to technical and financial difficulties of implementing coastal protection (*high confidence*). Above 1.5°C global warming level, limited freshwater resources pose potential hard limits for Small Islands and for regions dependent on glacier and snow-melt (*medium confidence*). By 2°C global warming level, soft limits are projected for multiple staple crops in many growing areas, particularly in tropical regions (*high confidence*). By 3°C global warming level, soft limits are projected for some water management measures for many regions, with hard limits projected for parts of Europe (*medium confidence*). Transitioning from incremental to transformational adaptation can help overcome soft adaptation limits (*high confidence*). (1.4, 4.7, 5.4, 5.8, 7.2, 7.3, 8.4, Table 8.6, 9.6, 10.4, 12.5, 13.2, 13.6, 16.4, 17.2, CCP1.3, Box CCP1.1, CCP2.3, CCP3.3, CCP4.4, CCP5.3, CCB SLR)

C.3.5 Adaptation does not prevent all losses and damages, even with effective adaptation and before reaching soft and hard limits. Losses and damages are unequally distributed across systems, regions and sectors and are not comprehensively addressed by current financial, governance and institutional arrangements, particularly in vulnerable developing countries. With increasing global warming, losses and damages increase and become increasingly difficult to avoid, while strongly concentrated among the poorest vulnerable populations. (*high confidence*) (1.4, 2.6, 3.4, 3.6, 6.3, Figure 6.4, 8.4, 13.2, 13.7, 13.10, 17.2, CCP2.3, CCP4.4, CCB LOSS, CCB SLR, CWGB ECONOMIC)

46 Climate literacy encompasses being aware of climate change, its anthropogenic causes and implications.

Avoiding Maladaptation

C.4 There is increased evidence of maladaptation[47] across many sectors and regions since the AR5. Maladaptive responses to climate change can create *lock-ins* of vulnerability, exposure and risks that are difficult and expensive to change and exacerbate existing inequalities. Maladaptation can be avoided by flexible, multi-sectoral, inclusive and long-term planning and implementation of adaptation actions with benefits to many sectors and systems. *(high confidence)* {1.3, 1.4, 2.6, Box 2.2, 3.2, 3.6, 4.6, 4.7, Box 4.3, Box 4.5, Figure 4.29, 5.6, 5.13, 8.2, 8.3, 8.4, 8.6, 9.6, 9.7, 9.8, 9.9, 9.10, 9.11, Box 9.5, Box 9.6, Box 9.9, Box 11.6, 13.11, 13.3, 13.4, 13.5, 14.5, 15.5, 15.6, 16.5, 17.2, 17.3, 17.4, 17.5, 17.6, CCP2.3, CCP2.3, CCP5.4, CCB DEEP, CCB NATURAL, CCB SLR, CWGB BIOECONOMY}

C.4.1 Actions that focus on sectors and risks in isolation and on short-term gains often lead to maladaptation if long-term impacts of the adaptation option and long-term adaptation commitments are not taken into account *(high confidence)*. The implementation of these maladaptive actions can result in infrastructure and institutions that are inflexible and/or expensive to change *(high confidence)*. For example, seawalls effectively reduce impacts to people and assets in the short-term but can also result in lock-ins and increase exposure to climate risks in the long-term unless they are integrated into a long-term adaptive plan *(high confidence)*. Adaptation integrated with development reduces lock-ins and creates opportunities (e.g., infrastructure upgrading) *(medium confidence)*. {1.4, 3.4, 3.6, 10.4, 11.7, Box 11.6, 13.2, 17.2, 17.5, 17.6, CCP 2.3, CCB DEEP, CCB SLR}

C.4.2 Biodiversity and ecosystem resilience to climate change are decreased by maladaptive actions, which also constrain ecosystem services. Examples of these maladaptive actions for ecosystems include fire suppression in naturally fire-adapted ecosystems or hard defences against flooding. These actions reduce space for natural processes and represent a severe form of maladaptation for the ecosystems they degrade, replace or fragment, thereby reducing their resilience to climate change and the ability to provide ecosystem services for adaptation. Considering biodiversity and autonomous adaptation in long-term planning processes reduces the risk of maladaptation. *(high confidence)* {2.4, 2.6, Table 2.7, 3.4, 3.6, 4.7, 5.6, 5.13, Table 5.21, Table 5.23, Box 9.1.2, 13.2, Box 13.2, 17.2, 17.5, CCP5.4}

C.4.3 Maladaptation especially affects marginalised and vulnerable groups adversely (e.g., Indigenous Peoples, ethnic minorities, low-income households, informal settlements), reinforcing and entrenching existing inequities. Adaptation planning and implementation that do not consider adverse outcomes for different groups can lead to maladaptation, increasing exposure to risks, marginalising people from certain socioeconomic or livelihood groups, and exacerbating inequity. Inclusive planning initiatives informed by cultural values, Indigenous knowledge, local knowledge, and scientific knowledge can help prevent maladaptation. *(high confidence)* (Figure SPM.4) {2.6, 3.6, 4.3, 4.6, 4.8, 5.12, 5.13, 5.14, 6.1, Box 7.1, 8.4, 11.4, 12.5, Box 13.2, 14.4, Box 14.1, 17.2, 17.5, 18.2, 17.2, CCP2.4}

C.4.4 To minimize maladaptation, multi-sectoral, multi-actor and inclusive planning with flexible pathways encourages low-regret[47] and timely actions that keep options open, ensure benefits in multiple sectors and systems and indicate the available solution space for adapting to long-term climate change *(very high confidence)*. Maladaptation is also minimized by planning that accounts for the time it takes to adapt *(high confidence)*, the uncertainty about the rate and magnitude of climate risk *(medium confidence)* and a wide range of potentially adverse consequences of adaptation actions *(high confidence)*. {1.4, 3.6, 5.12, 5.13, 5.14, 11.6, 11.7, 17.3, 17.6, CCP2.3, CCP2.4, CCP5.4, CCB DEEP, CCB SLR}

Enabling Conditions

C.5 Enabling conditions are key for implementing, accelerating and sustaining adaptation in human systems and ecosystems. These include political commitment and follow-through, institutional frameworks, policies and instruments with clear goals and priorities, enhanced knowledge on impacts and solutions, mobilization of and access to adequate financial resources, monitoring and evaluation, and inclusive governance processes. *(high confidence)* {1.4, 2.4, 3.6, 4.8, 6.4, 7.4, 8.5, 9.4, 10.5, 11.4, 11.7, 12.5, 13.11, 14.7, 15.6, 17.4, 18.4, CCP2.4, CCP5.4, CCB FINANCE, CCB MDIG}

C.5.1 Political commitment and follow-through across all levels of government accelerate the implementation of adaptation actions *(high confidence)*. Implementing actions can require large upfront investments of human, financial and technological resources *(high confidence)*, whilst some benefits could only become visible in the next decade or beyond *(medium confidence)*. Accelerating commitment and follow-through is promoted by rising public awareness, building business cases for adaptation, accountability and transparency mechanisms, monitoring and evaluation of adaptation progress, social movements, and climate-related litigation in some regions *(medium confidence)*. {3.6, 4.8, 5.8, 6.4, 8.5, 9.4, 11.7, 12.5, 13.11, 17.4, 17.5, 18.4, CCP2.4, CCB COMD}

47 *From AR5, an option that would generate net social welfare or benefits under current climate change and a range of future climate change scenarios, and represent one example of adaptation strategies.*

C.5.2 Institutional frameworks, policies and instruments that set clear adaptation goals and define responsibilities and commitments and that are coordinated amongst actors and governance levels, strengthen and sustain adaptation actions (*very high confidence*). Sustained adaptation actions are strengthened by mainstreaming adaptation into institutional budget and policy planning cycles, statutory planning, monitoring and evaluation frameworks and into recovery efforts from disaster events (*high confidence*). Instruments that incorporate adaptation such as policy and legal frameworks, behavioural incentives, and economic instruments that address market failures, such as climate risk disclosure, inclusive and deliberative processes strengthen adaptation actions by public and private actors (*medium confidence*). (1.4, 3.6, 4.8, 5.14, 6.3, 8.4, 7.4, 9.4, 10.4, 11.7, Box 11.6, Table 11.17, 13.10, 13.11, 14.7, 15.6, 17.3, 17.4, 17.5, 17.6, 18.4, CCP2.4, CCP5.4, CCP6.3, CCB DEEP)

C.5.3 Enhancing knowledge on risks, impacts, and their consequences, and available adaptation options promotes societal and policy responses (*high confidence*). A wide range of top-down, bottom-up and co-produced processes and sources can deepen climate knowledge and sharing, including capacity building at all scales, educational and information programmes, using the arts, participatory modelling and climate services, Indigenous knowledge and local knowledge and citizen science (*high confidence*). These measures can facilitate awareness, heighten risk perception and influence behaviours (*high confidence*). (1.3, 3.6, 4.8, 5.9, 5.14, 6.4, Table 6.8, 7.4, 9.4, 10.5, 11.1, 11.7, 12.5, 13.9, 13.11, 14.3, 15.6, 15.6, 17.4, 18.4, CCP2.4.1, CCB BEING)

C.5.4 With adaptation finance needs estimated to be higher than those presented in AR5, enhanced mobilization of and access to financial resources are essential for implementation of adaptation and to reduce adaptation gaps (*high confidence*). Building capacity and removing some barriers to accessing finance is fundamental to accelerate adaptation, especially for vulnerable groups, regions and sectors (*high confidence*). Public and private finance instruments include inter alia grants, guarantee, equity, concessional debt, market debt, and internal budget allocation as well as savings in households and insurance. Public finance is an important enabler of adaptation (*high confidence*). Public mechanisms and finance can leverage private sector finance for adaptation by addressing real and perceived regulatory, cost and market barriers, for example via public-private partnerships (*high confidence*). Financial and technological resources enable effective and ongoing implementation of adaptation, especially when supported by institutions with a strong understanding of adaptation needs and capacity (*high confidence*). (4.8, 5.14, 6.4, Table 6.10, 7.4, 9.4, Table 11.17, 12.5, 13.11, 15.6, 17.4, 18.4, Box 18.9, CCP5.4, CCB FINANCE)

C.5.5 Monitoring and evaluation (M&E) of adaptation are critical for tracking progress and enabling effective adaptation (*high confidence*). M&E implementation is currently limited (*high confidence*) but has increased since AR5 at local and national levels. Although most of the monitoring of adaptation is focused towards planning and implementation, the monitoring of outcomes is critical for tracking the effectiveness and progress of adaptation (*high confidence*). M&E facilitates learning on successful and effective adaptation measures, and signals when and where additional action may be needed. M&E systems are most effective when supported by capacities and resources and embedded in enabling governance systems (*high confidence*). (1.4, 2.6, 6.4, 7.4, 11.7, 11.8, 13.2, 13.11, 17.5, 18.4, CCP2.4, CCB DEEP, CCB ILLNESS, CCB NATURAL, CCB PROGRESS)

C.5.6 Inclusive governance that prioritises equity and justice in adaptation planning and implementation leads to more effective and sustainable adaptation outcomes (*high confidence*). Vulnerabilities and climate risks are often reduced through carefully designed and implemented laws, policies, processes, and interventions that address context specific inequities such as based on gender, ethnicity, disability, age, location and income (*high confidence*). These approaches, which include multi-stakeholder co-learning platforms, transboundary collaborations, community-based adaptation and participatory scenario planning, focus on capacity-building, and meaningful participation of the most vulnerable and marginalised groups, and their access to key resources to adapt (*high confidence*). (1.4, 2.6, 3.6, 4.8, 5.4, 5.8, 5.9, 5.13, 6.4, 7.4, 8.5, 11.8, 12.5, 13.11, 14.7, 15.5, 15.7, 17.3, 17.5, 18.4, CCP2.4, CCP5.4, CCP6.4, CCB GENDER, CCB HEALTH, CCB BEING)

D: Climate Resilient Development

Climate resilient development integrates adaptation measures and their enabling conditions (Section C) with mitigation to advance sustainable development for all. Climate resilient development involves questions of equity and system transitions in land, ocean and ecosystems; urban and infrastructure; energy; industry; and society and includes adaptations for human, ecosystem and planetary health. Pursuing climate resilient development focuses on both where people and ecosystems are co-located as well as the protection and maintenance of ecosystem function at the planetary scale. Pathways for advancing climate resilient development are development trajectories that successfully integrate mitigation and adaptation actions to advance sustainable development. Climate resilient development pathways may be temporarily coincident with any RCP and SSP scenario used throughout AR6, but do not follow any particular scenario in all places and over all time.

Conditions for Climate Resilient Development

D.1 Evidence of observed impacts, projected risks, levels and trends in vulnerability, and adaptation limits, demonstrate that worldwide climate resilient development action is more urgent than previously assessed in AR5. Comprehensive, effective, and inclusive responses can harness synergies and reduce trade-offs between adaptation and mitigation to advance sustainable development. (*very high confidence*) (2.6, 3.4, 3.6, 4.2, 4.6, 7.2, 7.4, 8.3, 8.4, 9.3, 10.6, 13.3, 13.8, 13.10, 14.7, 17.3, 18.3, Box 18.1, Figure 18.1, Table 18.5)

D.1.1 There is a rapidly narrowing window of opportunity to enable climate resilient development. Multiple climate resilient development pathways are still possible by which communities, the private sector, governments, nations and the world can pursue climate resilient development – each involving and resulting from different societal choices influenced by different contexts and opportunities and constraints on system transitions. Climate resilient development pathways are progressively constrained by every increment of warming, in particular beyond 1.5°C, social and economic inequalities, the balance between adaptation and mitigation varying by national, regional and local circumstances and geographies, according to capabilities including resources, vulnerability, culture and values, past development choices leading to past emissions and future warming scenarios, bounding the climate resilient development pathways remaining, and the ways in which development trajectories are shaped by equity, and social and climate justice, (*very high confidence*) (Figure TS.14d, 2.6, 4.7, 4.8, 5.14, 6.4, 7.4, 8.3, 9.4, 9.3, 9.4, 9.5, 10.6, 11.8, 12.5, 13.10, 14.7, 15.3, 18.5, CCP2.3, CCP3.4, CCP4.4, CCP5.3, CCP5.4, Table CCP5.2, CCP6.3, CCP7.5)

D.1.2 Opportunities for climate resilient development are not equitably distributed around the world (*very high confidence*). Climate impacts and risks exacerbate vulnerability and social and economic inequities and consequently increase persistent and acute development challenges, especially in developing regions and sub-regions, and in particularly exposed sites, including coasts, small islands, deserts, mountains and polar regions. This in turn undermines efforts to achieve sustainable development, particularly for vulnerable and marginalized communities (*very high confidence*). (2.5, 4.4, 4.7, 6.3, Box 6.4, Figure 6.5, 9.4, Table 18.5, CCP2.2, CCP3.2, CCP3.3, CCP5.4, CCP6.2, CCB HEALTH, CWGB [URBAN])

D.1.3 Embedding effective and equitable adaptation and mitigation in development planning can reduce vulnerability, conserve and restore ecosystems, and enable climate resilient development. This is especially challenging in localities with persistent development gaps and limited resources (*high confidence*). Dynamic trade-offs and competing priorities exist between mitigation, adaptation, and development. Integrated and inclusive system-oriented solutions based on equity and social and climate justice reduce risks and enable climate resilient development (*high confidence*). (1.4, 2.6, Box 2.2, 3.4, 4.7, 4.8, Box 4.5, Box 4.8, 5.13, 7.4, 8.5, 9.4, Box 9.3, 10.6, 12.5, 12.6, 13.3, 13.4, 13.10, 13.11, 14.7, 18.4, CCB DEEP, CCP2, CCP5.4, CCB HEALTH, SRCCL)

Enabling Climate Resilient Development

D.2 Climate resilient development is enabled when governments, civil society and the private sector make inclusive development choices, that prioritize risk reduction, equity and justice, and when decision-making processes, finance and actions are integrated across governance levels, sectors and timeframes (*very high confidence*). Climate resilient development is facilitated by international cooperation and by governments at all levels working with communities, civil society, educational bodies, scientific and other institutions, media, investors and businesses; and by developing partnerships with traditionally marginalized groups, including women, youth, Indigenous Peoples, local communities and ethnic minorities (*high confidence*). These partnerships are most effective when supported by enabling political leadership, institutions, resources, including finance, as well as climate services, information and decision support tools (*high confidence*). (Figure SPM.5) (1.3, 1.4, 1.5, 2.7, 3.6, 4.8, 5.14, 6.4, 7.4, 8.5, 8.6, 9.4, 10.6, 11.8, 12.5, 13.11, 14.7, 15.6, 15.7, 17.4, 17.6, 18.4, 18.5, CCP2.4, CCP3.4, CCP4.4, CCP5.4, CCP6.4, CCP7.6, CCB DEEP, CCB GENDER, CCB HEALTH, CCB MIDG, CCB NATURAL, CCB SLR)

D.2.1 Climate resilient development is advanced when actors work in equitable, just and enabling ways to reconcile divergent interests, values and worldviews, toward equitable and just outcomes (*high confidence*). These practices build on diverse knowledges about climate risk and chosen development pathways account for local, regional and global climate impacts, risks, barriers and opportunities (*high confidence*). Structural vulnerabilities to climate change can be reduced through carefully designed and implemented legal, policy, and process interventions from the local to global that address inequities based on gender, ethnicity, disability, age, location and income (*very high confidence*). This includes rights-based approaches that focus on capacity-building, meaningful participation of the most vulnerable groups, and their access to key resources, including financing, to reduce risk and adapt (*high confidence*). Evidence shows that climate resilient development processes links scientific, Indigenous, local, practitioner and other forms of knowledge, and are more effective and sustainable because they are locally appropriate and lead to more legitimate, relevant and effective actions (*high confidence*).

There is a rapidly narrowing window of opportunity to enable climate resilient development

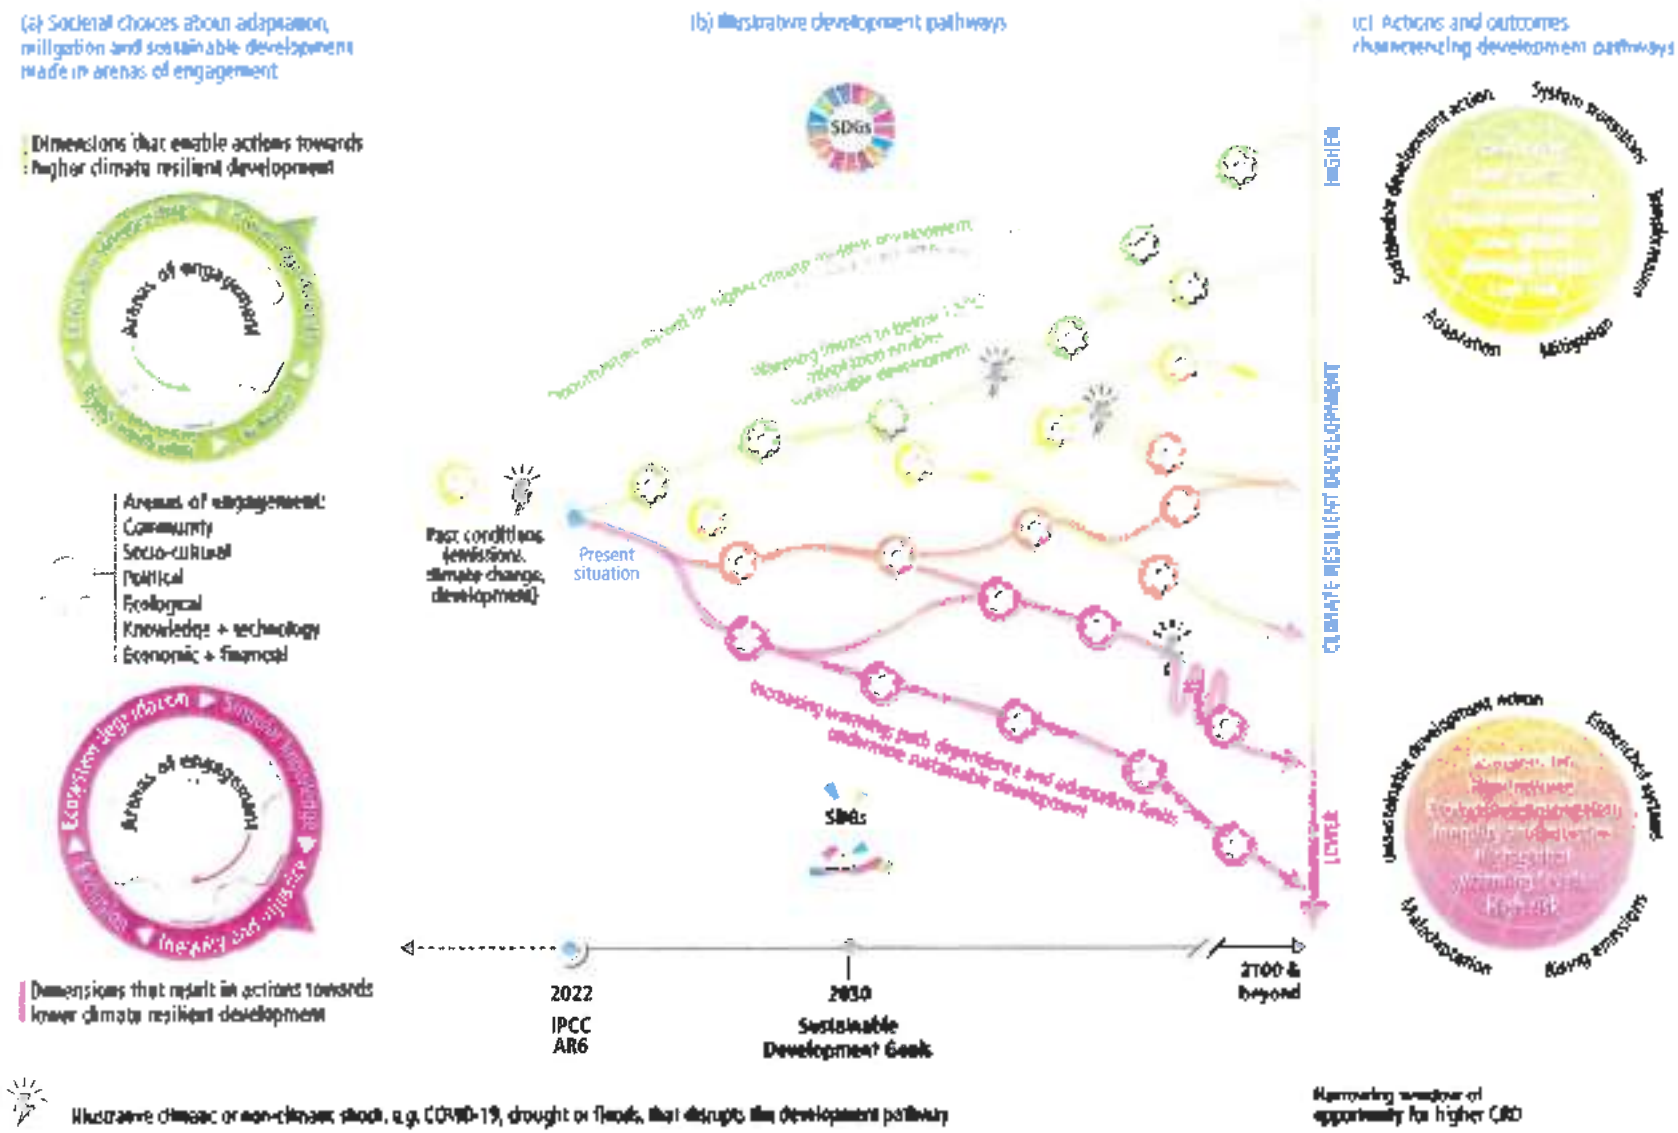


Figure SPM.5 | Climate resilient development (CRD) is the process of implementing greenhouse gas mitigation and adaptation measures to support sustainable development. This figure builds on Figure SPM.1 in AR5 WGII (depicting climate resilient pathways) by describing how CRD pathways are the result of cumulative societal choices and actions within multiple arenas.

Panel (a) Societal choices towards higher CRD (green cog) or lower CRD (red cog) result from interacting decisions and actions by diverse governance, private sector and civil society actors, in the context of climate risks, adaptation limits and development gaps. These actions engage with adaptation, mitigation and development actions in political, economic and financial, ecological, socio-cultural, knowledge and technology, and community arenas from local to international levels. Opportunities for climate resilient development are not equitably distributed around the world.

Panel (b) Cumulatively, societal choices, which are made continuously, shift global development pathways towards higher (green) or lower (red) climate resilient development. Past conditions (past emissions, climate change and development) have already eliminated some development pathways towards higher CRD (dashed green line).

Panel (c) Higher CRD is characterized by outcomes that advance sustainable development for all. Climate resilient development is progressively harder to achieve with global warming levels beyond 1.5°C. Inadequate progress towards the Sustainable Development Goals (SDGs) by 2030 reduces climate resilient development prospects. There is a narrowing window of opportunity to shift pathways towards more climate resilient development futures as reflected by the adaptation limits and increasing close to them, constraining the remaining carbon budgets. (Figure SPM.2, Figure SPM.3) (Figure TS.14b, 2.5, 3.6, 7.2, 7.3, 7.4, 8.3, 8.4, 8.5, 14.4, 16.5, 17.3, 17.4, 17.6, 18.1, 18.2, 18.3, 18.4, Box 18.1, Figure 18.1, Figure 18.2, Figure 18.3, CCB COVID, CCB GENDER, CCB HEALTH, CCB MDIG, CCB SLR, WGI AR6 Table SPM.1, WGI AR6 Table SPM.2, SR1.5 Figure SPM.1)

Pathways towards climate resilient development overcome jurisdictional and organizational barriers, and are founded on societal choices that accelerate and deepen key system transitions (*very high confidence*). Planning processes and decision analysis tools can help identify 'low regrets' options[48] that enable mitigation and adaptation in the face of change, complexity, deep uncertainty and divergent views (*medium confidence*). (1.3, 1.4, 1.5, 2.7, 3.6, 4.8, 5.14, 6.4, 7.4, 8.5, 8.6, Box 9.7, 9.4, Box 9.2, 10.6, 11.8, 12.5, 13.11, 14.7, 15.6, 15.7, 17.2–17.6, 18.2–18.4, CCP2.3–2.4, CCP3.4, CCP4.4, CCP5.4, CCP6.4, CCP7.6, CCB DEEP, CCB HEALTH, CCB MDIG, CCB NATURAL, CCB SLR)

D.2.2 Inclusive governance contributes to more effective and enduring adaptation outcomes and enables climate resilient development (*high confidence*). Inclusive processes strengthen the ability of governments and other stakeholders to jointly consider factors such as the rate and magnitude of change and uncertainties, associated impacts, and timescales of different climate resilient development pathways given past development choices leading to past emissions and scenarios of future global warming (*high confidence*). Associated societal choices are made continuously through interactions in arenas of engagement from local to international levels. The quality and outcome of these interactions helps determine whether development pathways shift towards or away from climate resilient development (*medium confidence*). (Figure SPM.5) (2.7, 3.6, 4.8, 5.14, 6.4, 7.4, 8.5, 8.6, 9.4, 10.6, 11.8, 12.5, 13.11, 14.7, 15.6, 15.7, 17.2–17.6, 18.2, 18.4, CCP2.3–2.4, CCP3.4, CCP4.4, CCP5.4, CCP6.4, CCP7.6, CCB GENDER, CCB HEALTH, CCB MDIG)

D.2.3 Governance for climate resilient development is most effective when supported by formal and informal institutions and practices that are well-aligned across scales, sectors, policy domains and timeframes. Governance efforts that advance climate resilient development account for the dynamic, uncertain and context-specific nature of climate-related risk, and its interconnections with non-climate risks. Institutions[48] that enable climate resilient development are flexible and responsive to emergent risks and facilitate sustained and timely action. Governance for climate resilient development is enabled by adequate and appropriate human and technological resources, information, capacities and finance. (*high confidence*) (2.7, 3.6, 4.8, 5.14, 6.3, 6.4, 7.4, 8.5, 8.6, 9.4, 10.6, 11.8, 12.5, 13.11, 14.7, 15.6, 15.7, 17.2–17.6, 18.2, 18.4, CCP2.3–2.4, CCP3.4, CCP4.4, CCP5.4, CCP6.4, CCP7.6, CCB DEEP, CCB GENDER, CCB HEALTH, CCB MDIG, CCB NATURAL, CCB SLR)

Climate Resilient Development for Natural and Human Systems

D.3 Interactions between changing urban form, exposure and vulnerability can create climate change-induced risks and losses for cities and settlements. However, the global trend of urbanisation also offers a critical opportunity in the near-term, to advance climate resilient development (*high confidence*). Integrated, inclusive planning and investment in everyday decision-making about urban infrastructure, including social, ecological and grey/physical infrastructures, can significantly increase the adaptive capacity of urban and rural settlements. Equitable outcomes contributes to multiple benefits for health and well-being and ecosystem services, including for Indigenous Peoples, marginalized and vulnerable communities (*high confidence*). Climate resilient development in urban areas also supports adaptive capacity in more rural places through rebalancing peri-urban supply chains of goods and services and financial flows (*medium confidence*). Coastal cities and settlements play an especially important role in advancing climate resilient development (*high confidence*). (6.2, 6.3, Table 6.6, 7.4, 8.6, Box 9.8, 18.3, CCP2.1, CCP2.2, CCP6.2, CWG1 URBAN)

48 Institutions: Rules, norms and customs that guide, constrain or enable human behaviours and practices. Institutions can be formally established, for instance through laws and regulations, or informally established, for instance by traditions or customs. Institutions may spur, hinder, strengthen, weaken or distort the emergence, adoption, and implementation of climate action and climate governance.

D.3.1 Taking integrated action for climate resilience to avoid climate risk requires urgent decision making for the new built environment and retrofitting existing urban design, infrastructure and land use. Based on socioeconomic circumstances, adaptation and sustainable development actions will provide multiple benefits including for health and well-being, particularly when supported by national governments, non-governmental organisations and international agencies that work across sectors in partnerships with local communities. Equitable partnerships between local and municipal governments, the private sector, Indigenous Peoples, local communities, and civil society can, including through international cooperation, advance climate resilient development by addressing structural inequalities, insufficient financial resources, cross-city risks and the integration of Indigenous knowledge and local knowledge *(high confidence)* [6.2, 6.3, 6.4, Table 6.6, 7.4, 8.5, 9.4, 10.5, 12.5, 17.4, Table 17.8, 18.2, Box 18.1, CCP2.4, CCB FINANCE, CCB GENDER, CCB INDIG, CWGB URBAN]

D.3.2 Rapid global urbanisation offers opportunities for climate resilient development in diverse contexts from rural and informal settlements to large metropolitan areas *(high confidence)*. Dominant models of energy intensive and market-led urbanisation, insufficient and misaligned finance and a predominant focus on grey infrastructure in the absence of integration with ecological and social approaches, risks missing opportunities for adaptation and locking in maladaptation *(high confidence)*. Poor land use planning and siloed approaches to health, ecological and social planning also exacerbate vulnerability in already marginalised communities *(medium confidence)*. Urban climate resilient development is observed to be more effective if it is responsive to regional and local land use development and adaptation gaps, and addresses the underlying drivers of vulnerability *(high confidence)*. The greatest gains in well-being can be achieved by prioritizing finance to reduce climate risk for low-income and marginalized residents including people living in informal settlements *(high confidence)*. [5.14, 6.1, 6.2, 6.3, 6.4, 6.5, Figure 6.5, Table 6.6, 7.4, 8.5, 8.6, 9.8, 9.9, 10.4, Table 17.8, 18.2, CCP2.2, CCP5.4, CCB HEALTH, CWGB URBAN]

D.3.3 Urban systems are critical, interconnected sites for enabling climate resilient development, especially at the coast. Coastal cities and settlements play a key role in moving toward higher climate resilient development given firstly, almost 11% of the global population – 896 million people – lived within the Low Elevation Coastal Zone[49] in 2020, potentially increasing to beyond 1 billion people by 2050, and these people, and associated development and coastal ecosystems, face escalating climate compounded risks, including sea level rise. Secondly, these coastal cities and settlements make key contributions to climate resilient development through their vital role in national economies and inland communities, global trade supply chains, cultural exchange, and centres of innovation. *(high confidence)* [6.1, 6.2, 6.4, Table 6.6, Box 15.2, SMCCP Table 2.1, CCP2.2, CCP2.4, CCB SLR, XWGB URBAN, SROCC Chapter 4]

D.4 Safeguarding biodiversity and ecosystems is fundamental to climate resilient development, in light of the threats climate change poses to them and their roles in adaptation and mitigation *(very high confidence)*. Recent analyses, drawing on a range of lines of evidence, suggest that maintaining the resilience of biodiversity and ecosystem services at a global scale depends on effective and equitable conservation of approximately 30% to 50% of Earth's land, freshwater and ocean areas, including currently near-natural ecosystems *(high confidence)*. [2.4, 2.5, 2.6, 3.4, 3.5, 3.6, Box 3.4, 12.5, 13.3, 13.4, 13.5, 13.10, CCB INDIG, CCB NATURAL]

D.4.1 Building the resilience of biodiversity and supporting ecosystem integrity[50] can maintain benefits for people, including livelihoods, human health and well-being and the provision of food, fibre and water, as well as contributing to disaster risk reduction and climate change adaptation and mitigation. [2.2, 2.5, 2.6, Table 2.6, Table 2.7, 3.5, 3.6, 5.4, 5.13, 5.14, Box 5.11, 12.5, CCP5.4, CCB COVID, CCB GENDER, CCB ILLNESS, CCB INDIG, CCB MIGRATE, CCB NATURAL]

D.4.2 Protecting and restoring ecosystems is essential for maintaining and enhancing the resilience of the biosphere *(very high confidence)*. Degradation and loss of ecosystems is also a cause of greenhouse gas emissions and is at increasing risk of being exacerbated by climate change impacts, including droughts and wildfire *(high confidence)*. Climate resilient development avoids adaptation and mitigation measures that damage ecosystems *(high confidence)*. Documented examples of adverse impacts of land-based measures intended as mitigation, when poorly implemented, include afforestation of grasslands, savannas and peatlands, and risks from bioenergy crops at large scale to water supply, food security and biodiversity *(high confidence)*. [2.4, 2.5, Box 2.2, 3.4, 3.5, Box 3.4, Box 9.3, CCP7.3, CCB NATURAL, CWGB BIOECONOMY]

---

49 LECZ: coastal areas below 10 m of elevation above sea level that are hydrologically connected to the sea.

50 Ecosystem integrity refers to the ability of ecosystems to maintain key ecological processes, recover from disturbance, and adapt to new conditions.

D.4.3 Biodiversity and ecosystem services have limited capacity to adapt to increasing global warming levels, which will make climate resilient development progressively harder to achieve beyond 1.5°C warming (*very high confidence*). Consequences of current and future global warming for climate resilient development include reduced effectiveness of Ecosystem-based Adaptation and approaches to climate change mitigation based on ecosystems and amplifying feedbacks to the climate system (*high confidence*). (Figure TS.14d, 2.4, 2.5, 2.6, 3.4, Box 3.4, 3.5, 3.6, Table 5.2, 12.5, 13.2, 13.3, 13.10, 14.5, 14.5, Box 14.3, 15.3, 17.3, 17.6, CCP5.3, CCP5.4, CCB EXTREMES, CCB ILLNESS, CCB NATURAL, CCB SLR, SR1.5, SROCC, SROCC)

Achieving Climate Resilient Development

D.5 It is unequivocal that climate change has already disrupted human and natural systems. Past and current development trends (past emission, development and climate change) have not advanced global climate resilient development (*very high confidence*). Societal choices and actions implemented in the next decade determine the extent to which medium- and long-term pathways will deliver higher or lower climate resilient development (*high confidence*). Importantly climate resilient development prospects are increasingly limited if current greenhouse gas emissions do not rapidly decline, especially if 1.5°C global warming is exceeded in the near-term (*high confidence*). These prospects are constrained by past development, emissions and climate change, and enabled by inclusive governance, adequate and appropriate human and technological resources, information, capacities and finance (*high confidence*). (Figure TS.14d, 1.2, 1.4, 1.5, 2.6, 2.7, 3.6, 4.7, 4.8, 5.14, 6.4, 7.4, 8.3, 8.5, 8.6, 9.3, 9.4, 9.5, 10.6, 11.8, 12.5, 13.10, 13.11, 14.7, 15.3, 15.6, 15.7, 16.2, 16.4, 16.5, 16.6, 17.2–17.6, 18.2–18.5, CCP2.3–2.4, CCP3.4, CCP4.4, CCP5.3, CCP5.4, Table CCP5.2, CCP6.3, CCP6.4, CCP7.5, CCP7.6, CCB DEEP, CCB HEALTH, CCB INEQ, CCB NATURAL, CCB SLR)

D.5.1 Climate resilient development is already challenging at current global warming levels (*high confidence*). The prospects for climate resilient development will be further limited if global warming levels exceeds 1.5°C (*high confidence*) and not be possible in some regions and sub-regions if the global warming level exceeds 2°C (*medium confidence*). Climate resilient development is most constrained in regions/subregions in which climate impacts and risks are already advanced, including low-lying coastal cities and settlements, small islands, deserts, mountains and polar regions (*high confidence*). Regions and subregions with high levels of poverty, water, food and energy insecurity, vulnerable urban environments, degraded ecosystems and rural environments, and/or few enabling conditions, face many non-climate challenges that inhibit climate resilient development which are further exacerbated by climate change (*high confidence*). (Figure TS.14d, 1.2, Box 6.6, 9.3, 9.4, 9.5, 10.6, 11.8, 12.5, 13.10, 14.7, 15.3, CCP2.3, CCP3.4, CCP4.4, CCP5.3, Table CCP5.2, CCP6.3, CCP7.5)

D.5.2 Inclusive governance, investment aligned with climate resilient development, access to appropriate technology and rapidly scaled-up finance, and capacity building of governments at all levels, the private sector and civil society enable climate resilient development. Experience shows that climate resilient development processes are timely, anticipatory, integrative, flexible and action focused. Common goals and social learning build adaptive capacity for climate resilient development. When implementing adaptation and mitigation together, and taking trade-offs into account, multiple benefits and synergies for human well-being as well as ecosystem and planetary health can be realised. Prospects for climate resilient development are increased by inclusive processes involving local knowledge and Indigenous Knowledge as well as processes that coordinate across risks and institutions. Climate resilient development is enabled by increased international cooperation including mobilising and enhancing access to finance, particularly for vulnerable regions, sectors and groups. (*high confidence*) (Figure SPM.5) (2.7, 3.6, 4.8, 5.14, 6.4, 7.4, 8.5, 8.6, 9.4, 10.6, 11.8, 12.5, 13.11, 14.7, 15.6, 15.7, 17.2–17.6, 18.2–18.5, CCP2.3–2.4, CCP3.4, CCP4.4, CCP5.4, CCP6.4, CCP7.6, CCB DEEP, CCB HEALTH, CCB INEQ, CCB NATURAL, CCB SLR)

D.5.3 The cumulative scientific evidence is unequivocal: Climate change is a threat to human well-being and planetary health. Any further delay in concerted anticipatory global action on adaptation and mitigation will miss a brief and rapidly closing window of opportunity to secure a liveable and sustainable future for all (*very high confidence*) (1.2, 1.4, 1.5, 16.2, Table SM16.24, 16.4, 16.5, 16.6, 17.3, 17.5, 17.6, 18.3, 18.4, 18.5, CCB DEEP, CWGB URBAN, WGI AR6 SPM, SROCC SPM, SRCCL SPM)

8228

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DSARE/PASA
accepted reason. Activities associated with the Project could further pressure this species by physically harming individual seals, and by disrupting the seals' food supply. 84. The Pisces Report states that Cape fur seals are unlikely to be found in the project area, citing map that shows generalized foraging areas that extend nearly exactly to the edge of the reconnaissance area.[90] However, the report also states, "[s]eals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles (~220 km) offshore,"[91] meaning a large part of the reconnaissance area is well within the foraging range of Cape fur seals. Moreover, the Based on the questionable assumption that Cape fur seals are unlikely to occur within the reconnaissance area, the Pisces Report authors deemed their sensitivity to the proposed seismic operations to be "LOW," in spite of the finding that "The potential impact of physiological injury to seals as a result of seismic noise is deemed to be of HIGH intensity."[92] Whales and dolphins 85. There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.[93] 86. The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the	were more associated with operational dynamics of the Namibian fleets and their licensing conditions that had reduced their effort (as South African vessels were not permitted to fish in Namibian waters). Cumulative impacts are assessed in Section 9 of the BA report. For both technical and commercial reasons, it is unlikely that concurrent seismic surveys will be undertaken in the same area during the same survey window. However, the cumulative impacts associated with multiple surveys was assessed and detailed in Section 9.3.5 of the BAR. Section 9.3.5 of the BA Report states that "three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures. This relates to the large pelagic long-line sector only, and only in the event that all three surveys are undertaken simultaneously. It should be noted that the seismic industry typically avoids simultaneous surveys occurring in close proximity to each other as this has the potential to degrade the quality of the recorded survey data. Other cumulative impacts are all expected to be low after mitigation is applied – therefore overall cumulative impacts are considered low post-mitigation. It should also be noted that of the three potential surveys cited by the Appellants, the GX Technologies survey should be disregarded as the company went into liquidation in 2022. The appellants' contention that up to 30% of the revenue generated by the impacted fisheries would be lost during the 70 day period is unsubstantiated and vague for the following reasons:

GROUNDS OF APPEAL	RESPONDING STATEMENT BY THE APPLICANT	COMMENTS BY THE DMRE/PASA
airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.[94] **Fish** 87. The BAR downplays the impacts of seismic surveys on fish and the fisheries they support, particularly in the case of the large pelagic longline fishery and the tuna pole-line fishery. While the BAR assesses the exclusion of fishing vessels due to temporary safety zones during seismic surveys, it fails to adequately assess the actual impacts of seismic activities on the target fish species themselves, both in the short and long-term. During the seismic survey, fishing vessels would be required to maintain a safe operational distance from the survey vessel and streamer array, which may extend up to 6 nautical miles. The FBAR assessed the impact of potential exclusion for each commercial sector based on the affected area of fishing ground and the amount of catch reported within the Reconnaissance Permit area. Given the location of the Reconnaissance Permit application area, two high-value fisheries are directly impacted: the large pelagic longline fishery (targeting tuna, swordfish and shark) and the tuna pole-line fishery. 88. The FBAR concluded that the Project's activities will result in exclusion to fishing grounds for at least the large pelagic longline fishery. The FBAR states that "[t]here is a high probability that the large pelagic longline sector (targeting tuna, swordfish and shark) will experience loss of access to fishing ground over the duration of the	◦ The four-month window is proposed to coincide with the period of lowest activities for the fisheries that operate in the potentially affected sectors; ◦ It should further be noted that the survey will not be undertaken over the entire tuna fisheries area or the whole application area at the same time and will thus not lead to a complete shutdown of the fishing activities in the pelagic longline sector during the 70 day period of the survey; and ◦ The mitigation measures included in Section 9.3.2 of the BAR provide for avoidance of the peak fishing periods and, furthermore, for the establishment of clear communication channels to be established with the other users of the survey area and to ensure that the disturbance within this sector is reduced to the absolute minimum. The impact on the affected fishing sectors was assessed to be of low significance and short duration and it could thus not be stated that "The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna." Impacts of cumulative sound exposure on marine mammals are evaluated using disturbance and injury threshold, defined as temporary threshold shifts (TTS) and permanent threshold shifts (PTS) (Southall et al. 2019). The audibility of a noise pertains only to the perception or detection of a sound above background levels of ambient noise. The thresholds established by Southall et al. (2019) are internationally regarded as standard references for environmental impact assessment of underwater noise. Although the modelling report doesn't specifically reference the CBA areas, the purpose of the modelling was to model the likely sound transmission and contours. The outputs of the model were then

EXECUTIVE SUMMARY

TGS Geophysical Company (UK) Ltd proposes to undertake 3D seismic acquisition in the Orange Basin off the West Coast of South Africa. The survey will comprise the acquisition of up to ~57 400 km² of 3D seismic data over a period of ~70 days, during the best available window of opportunity in either 2023 or 2024, subject to granting of the Reconnaissance Permit and vessel availability.

The Reconnaissance Permit Area, which is approximately 57 400 km² in size, is located in water depths ranging from ~1 500 m to nearly 4 000 m off the South African West Coast between Alexander Bay and Cape Columbine. The seabed sediments comprise sandy muds. Although influenced by the Benguela Current the Reconnaissance Permit area is located on the western extent of the coastal upwelling cells. Winds come primarily from the southeast, whereas virtually all swells throughout the year come from the S and SSW direction. The bulk of the seawater in the study area is South Atlantic Central Water characterised by low oxygen concentrations, especially at depth. Surface waters in the Reconnaissance Permit Application area will primarily be nutrient poor and clear, being beyond the influence of coastal upwelling, with seasonal nutrient peaks expected on the eastern edge of the Reconnaissance Permit Area during periods of upwelling.

The proposed 3D survey area falls into the Southeast Atlantic Deep Ocean Ecoregions. Although there is a lack of knowledge of the community structure and diversity of benthic macrofauna off the shelf edge, the South Atlantic bathyal and abyssal unconsolidated habitat types have been rated as 'Least Threatened', reflecting the great extent of these habitats in the South African Exclusive Economic Zone (EEZ). Only sections along the shelf edge and in the Cape Canyon are rated as 'Vulnerable' and 'Endangered'. Geological features of note in and adjacent to the proposed survey area are Child's Bank situated at about 31°S and Tripp Seamount situated at about 29°40'S. Two canyons, the Cape Canyon and Cape Valley also occur to the south of the Reconnaissance Permit Area. Features such as banks and seamounts often host deep-water corals and boast an enrichment of bottom-associated communities relative to the otherwise low-profile, homogenous seabed habitats.

Due to its offshore location, plankton abundance is expected to be low, with the major fish spawning and migration routes occurring inshore on the shelf. The dominant fish in the area would include the migratory large pelagic species such as tunas, billfish and pelagic sharks. Seabirds will be dominated by the pelagic species such as albatross, petrels and shearwaters. Migrating turtles in the area would include the leatherback and loggerhead turtles. Marine mammals likely to occur offshore include a variety of baleen whales including humpbacks, Antarctic minke, fin and sei whales. Toothed whales will include sperm and killer whales, as well as a variety of beaked whales and dolphins. There are six offshore Marine Protected Areas (MPAs) in the general project area but none fall within the Reconnaissance Permit Area. The proposed 3D survey area lies well offshore of these MPAs. There is some overlap of the Reconnaissance Permit Area with the Orange Seamount and Canyon Complex Ecologically and Biologically Significant Areas (EBSAs). Critical biodiversity areas (CBAs) within the Reconnaissance Permit area include both CBA1: natural and CBA2: natural areas, with a small section of CBA2: restore being located in the north.

Potential impacts to the marine fauna as a result of the proposed 3D seismic acquisition include:

- Physiological injury and/or mortality;
- Behavioural avoidance;
- Reduced reproductive success/spawning;
- Masking of environmental sounds and communication;
- Collision of turtles/marine mammals with the survey and support vessels or entanglement in towed acoustic apparatus; and
- Indirect impacts on piscivorous predators due to seismic effects on prey species.

The highest sensitivities in response to the proposed 3D surveys are:

- Humpback whales, which migrate through the area between June and November (inclusive);
- Sperm whales, beaked whales and other odontocetes that frequent offshore waters;
- Large migratory pelagic fish and shark species that show seasonal association with Child's Bank and Tripp Seamount;
- Leatherback turtles which frequent offshore waters in low numbers and aggregate around seamounts to feed on jellyfish; and
- Various pelagic Albatross, Petrel, Storm Petrel and Shearwater species.

The impacts before and after mitigation on marine habitats and communities associated with seismic noise are summarised below:

Impact	Significance (before mitigation)	Significance (after mitigation)
Plankton and ichthyoplankton	Medium	Very Low
Marine invertebrates	Negligible	Negligible
Pelagic Fish	Medium	Low
Diving Seabirds	Low	Very Low
Turtles	Medium	Low
Seals	Low	Very Low
Whales and dolphins		
Baleen whale	Medium	Low
Toothed whales and dolphins	Medium	Low

Other impacts before and after mitigation on marine habitats and communities associated with the proposed project are summarised below:

Impact	Significance (before mitigation)	Significance (after mitigation)
Non-seismic noise - helicopter	Low	Low
Non-seismic noise - vessel	Very Low	Very Low
Vessel lighting	Very Low	Very Low
Hull fouling and ballast water discharge	Very Low	Negligible
Waste Discharges to sea	Very Low	Very Low
Ship strikes and entanglement in gear	Low	Low
Accidental loss of equipment	Very Low	Very Low
Operational spills and vessel collision	Medium	Low

The mitigation measures proposed for seismic surveys are as provided below for each phase of a seismic survey operation:

No.	Mitigation measure	Classification
1. Survey Planning		
1.1	Plan seismic surveys to avoid sensitive areas and periods for some marine fauna: • Movement of migratory cetaceans (particularly baleen whales) from their southern feeding grounds into low latitude waters (June/July and late October/November), and their aggregation on the summer feeding grounds between St Helena Bay and Dassen Island from late October to late December and ensure that migration paths are not blocked by seismic operations. If possible the survey should be undertaken from North to South to avoid these feeding aggregations.	Avoid
1.2	Plan survey, as far as possible, so that the first commencement of airgun firing in a new area (including gun tests) are undertaken during daylight hours.	Abate on site
1.3	Prohibit airgun use (including airgun tests) outside of the Reconnaissance Permit Area.	Avoid
1.4	Although a seismic vessel and its gear may pass through a declared Marine Protected Area, acoustic sources (airguns) must not be operational during this transit.	Avoid
1.5	A 5 km buffer zone where no airgun operation is permitted is recommended around all MPAs	Avoid
2. Key Equipment		
2.1	**Passive Acoustic Monitoring (PAM)**	
2.1.1	Ensure the seismic vessel is fitted with Passive Acoustic Monitoring (PAM) technology, which detects some animals through their vocalisations.	Abate on site
2.1.2	As the survey area would largely be in waters deeper than 1 000 m where sperm whales and other deep-diving odontocetes are likely to be encountered, implement the use of PAM 24-hr a day when the airgun is in operation.	Abate on site
2.1.3	Ensure that the PAM hydrophone streamer is towed in such a way that the interference of vessel noise is minimised.	Abate on site
2.1.4	Ensure the PAM streamer is fitted with at least four hydrophones, of which two are HF and two LF, to allow directional detection of cetaceans.	Abate on site

No.	Mitigation measure	Classification
2.1.5	Ensure spare PAM hydrophone streamers (e.g. 4 heavy tow cables and 6 hydrophone cables) are readily available in the event that PAM breaks down, in order to ensure timeous redeployment.	Abate on site
2.2	Acoustic Source	
2.2.1	Define and enforce the use of the lowest practicable airgun volume for production, and design arrays to maximise downward propagation, minimise horizontal propagation and minimise high frequencies in airgun pulses.	Abate on site
2.2.2	Ensure a display screen for the acoustic source operations is provided to the marine observers. All information relating to the activation of the acoustic source and the power output levels must be readily available to support the observers in real time via the display screen and to ensure that operational capacity is not exceeded.	Abate on site
2.2.3	Ensure the ramp-up noise volumes do not exceed the production volume.	Abate on site
2.3	Streamers	
2.3.1	Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'.	Abate on site
2.3.2	Ensure that solid streamers rather than fluid-filled streamers are used to avoid leaks.	Avoid
3. Key Personnel		
3.1	• Make provision for the placing of a qualified MMOs on board the seismic vessel. As a minimum, one must be on watch during daylight hours for the pre-shoot observations and when the acoustic source is active. • The duties of the MMO would be to: – Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations; – Record airgun activities, including sound levels, "soft-start" procedures and pre-firing regimes; – Observe and record responses of marine fauna to seismic shooting from optimum vantage points, including seabird, large pelagic fish (e.g. shoaling tuna, sunfish, sharks), turtle, seal and cetacean incidence and behaviour and any mortality or injuries of marine fauna as a result of the seismic survey. Data captured should include species identification, position (latitude/longitude), distance/bearing from the vessel, swimming speed and direction (if applicable) and any obvious changes in behaviour (e.g. startle responses or changes in surfacing/diving frequencies, breathing patterns) as a result of the seismic activities. Both the identification and the behaviour of the animals must be recorded accurately along with current seismic sound levels. Any attraction of predatory seabirds, large pelagic fish or cetaceans (by mass disorientation or stunning of fish as a result of seismic survey activities) and incidents of feeding behaviour among the hydrophone streamers should also be recorded; – Record sightings of any injured or dead marine mammals, large pelagic fish (e.g. sharks), seabirds and sea turtles, regardless of whether the injury or death was caused by the seismic vessel itself. If the injury or death was caused by a collision with the seismic vessel, the date and location (latitude/longitude) of the strike, and the species identification or a description of the animal should be recorded and included as part of the daily report;	Abate on site

No.	Mitigation	Classification
	– Record meteorological conditions at the beginning and end of the observation period, and whenever the weather conditions change significantly; – Request the delay of start-up or temporary termination of the seismic survey or adjusting of seismic shooting, as appropriate. It is important that MMO decisions on the termination of firing are made confidently and expediently, and following dialogue between the observers on duty at the time. A log of all termination decisions must be kept (for inclusion in both daily and "close-out" reports); – Use a recording spreadsheet (e.g. JNCC, 2017) in order to record all the above observations and decisions; and – Prepare daily reports of all observations, to be forwarded to the necessary authorities as required, in order to ensure compliance with the mitigation measures.	
3.2	• Make provision for placing of a qualified PAM operator on board the seismic vessel. As a minimum, one must be on 'watch' during the pre-shoot observations and when the acoustic source is active. • The duties of the PAM operator would be to: – Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations; – Ensure that the hydrophone cable is optimally placed, deployed and tested for acoustic detections of marine mammals; – Confirm that there is no marine mammal activity within 500 m of the airgun array prior to commencing with the "soft-start" procedures; – Record species identification, position (latitude/longitude), distance and bearing from the vessel and acoustic source, where possible; – Record general environmental conditions; – Record airgun activities, including sound levels, "soft-start" procedures and pre-firing regimes; and – Request the delay of start-up and temporary termination of the seismic survey, as appropriate.	Abate on site
3.3.	Ensure MMOs and PAM operators are briefed on the area-specific sensitivities and on the seismic survey planning (including roles and responsibilities, and lines of communication).	Abate on site
4. Airgun Testing		
4.1	Maintain a pre-shoot watch of 60-minutes before any instances of airgun testing. If only a single lowest power airgun is tested, the pre-shoot watch period can be reduced to 30 minutes.	Avoid / Abate on site
4.2	Implement a "soft-start" procedure if testing multiple airguns. • The "soft-start" should be carried out over a time period proportional to the number of guns being tested and not exceed 20 minutes; airguns should be tested in order of increasing volume; • If testing all airguns at the same time, a 20 minute "soft-start" is required; • If testing a single lowest power airgun a "soft-start" is not required.	Avoid / Abate on site

No.	Mitigation Measure	Implementation
5.1	Implement a dedicated MMO and PAM pre-shoot watch of at least 60 minutes (to accommodate deep-diving species in water depths greater than 200 m).	Avoid / Abate on site
5.2	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if: • during daylight hours it is confirmed: - visually by the MMO during the pre-shoot watch (60 minutes) that there are no penguins or feeding aggregations of diving seabirds, shoaling large pelagic fish, turtles, seals or cetaceans within 500 m of the seismic source, and - by PAM technology that there are no vocalising cetaceans detected in the 500 m mitigation zone. • during times of poor visibility or darkness it is confirmed by PAM technology that no vocalising cetaceans are present in the 500 m mitigation zone during the pre-shoot watch (60 minutes).	Avoid / Abate on site
5.3	Delay "soft-starts" if penguins or feeding aggregations of diving seabirds, shoaling large pelagic fish, turtles, seals or cetaceans are observed within the mitigation zone. • A "soft-start" should not begin until 30 minutes after cetaceans depart the 500 m mitigation zone or 30 minutes after they are last seen or acoustically detected by PAM in the mitigation zone. • In the case of penguins, diving seabirds, shoaling large pelagic fish and turtles, delay the "soft-start" until animals are outside the 500 m mitigation zone. • In the case of fur seals, which may occur commonly around the vessel, delay "soft-starts" for at least 10 minutes until it has been confirmed that the mitigation zone is clear of all seal activity. However, if after a period of 10 mins seals are still observed within 500 m of the airgun, the normal "soft-start" procedure should be allowed to commence for at least a 20-minute duration. Seal activity should be carefully monitored during "soft-starts" to determine if they display any obvious negative responses to the airgun and gear or if there are any signs of injury or mortality as a direct result of the seismic activities.	Avoid / Abate on site
5.4	As noted above for planning, when arriving at the survey area for the first time, survey activities should, as far as possible, only commence during daylight hours with good visibility. However, if this is not possible due to prolonged periods of poor visibility (e.g. thick fog) or unforeseen technical issue which results in a night-time start, the initial acoustic source activation (including gun tests) may only be undertaken if the normal 60-minute PAM pre-watch and "soft-start" procedures have been followed.	Avoid / Abate on site
5.5	Schedule "soft-starts" so as to minimise, as far as possible, the interval between reaching full power operation and commencing a survey line. The period between the end of the soft start and commencing with a survey line must not exceed 20 minutes. If it does exceed 20 minutes, refer to breaks in firing below.	Abate on site

No.	Mitigation measure	Classification
6. Line Turns		
6.1	If line changes are expected to take longer than 40 minutes: • Terminate airgun firing at the end of the survey line and implement a pre-shoot search (60 minutes) and "soft-start" procedure (20 minutes) when approaching the next survey line. • If line turn is shorter than 80 minutes (i.e. shorter than a 60-minute pre-shoot watch and 20-minute "soft-start" combined), the pre-shoot watch can commence before the end of the previous survey line.	Abate on site
6.2	If line changes are expected to take less than 40 minutes, airgun firing can continue during the line change if: • The power is reduced to 180 cubic inches (or as close as is practically feasible) at standard pressure. Airgun volumes of less than 180 cubic inches can continue to fire at their operational volume and pressure; • The Shot Point Interval (SPI) is increased to provide a longer duration between shots, with the SPI not to exceed 5 minutes; and • The power is increased and the SPI is decreased in uniform stages during the final 10 minutes of the line change (or geophone repositioning), prior to data collection re-commencing (i.e. a form of mini soft start). • Normal MMO and PAM observations continue during this period when reduced power airgun is firing.	Abate on site
7. Shut-Downs		
7.1	Terminate seismic shooting on: • observation and/or detection of penguins or feeding aggregations of diving seabirds, turtles, slow swimming large pelagic fish (including whale sharks, basking sharks, manta rays) or cetaceans within the 500 m mitigation zone. • observation of any obvious mortality or injuries to cetaceans, turtles, seals or mass mortalities of squid and fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO to be as a direct result of the survey.	Abate on site
7.2	Depending the species, specific mitigation will be implemented to continue the survey operations, as specified below: • For specific species such as turtles, penguins, diving seabirds and slow swimming large pelagic fish (including whale sharks, basking sharks, manta rays), terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required). • For cetaceans, terminate shooting until such time as there has been a 30 minute delay from the time the animal was last sighted within the mitigation zone before the commencement of the normal soft start procedure.	Abate on site

No.	Mitigation measure	Classification
8. Breaks in Airgun Firing		
8.1	If after breaks in firing, the airgun can be restarted within 5 minutes, no soft-start is required and firing can recommence at the same power level provided no marine mammals have been observed or detected in the mitigation zone during the break-down period.	Abate on site
8.2	For all breaks in firing of longer than 5 minutes, but less than 20 minutes, implement a "soft-start" of similar duration, assuming there is continuous observation by the MMO and PAM operator during the break.	Abate on site
8.3	For all breaks in firing of 20 minutes or longer, implement a 60-minute pre-shoot watch and 20-minute "soft-start" procedure prior to the survey operation continuing.	Abate on site
8.4	For planned breaks, ensure that there is good communication between the seismic contractor and MMOs and PAM operators in order for all parties to be aware of these breaks and that early commencement of pre-watch periods can be implemented to limit delays.	Abate on site
9. PAM Malfunctions		
9.1	If the PAM system malfunctions or becomes damaged during night-time operations or periods of low visibility, continue operations for 30 minutes without PAM if no marine mammals were detected by PAM in the mitigation zones in the previous 2 hours, while the PAM operator diagnoses the issue. If after 30 minutes the diagnosis indicates that the PAM gear must be repaired to solve the problem, reduce power to 190 cubic inches. Firing of the reduced power gun may continue for 30 minutes while PAM is being repaired, the last 10-minute of which is a 10-minute ramp-up to full power (mini "soft-start"). If the PAM repair will take longer than 60 minutes, stop surveying until such time as a functional PAM system can be redeployed and tested.	Abate on site
9.2	If the PAM system breaks down during daylight hours, continue operations for 30 minutes without PAM, while the PAM operator diagnoses the issue. If the diagnosis indicates that the PAM gear must be repaired to solve the problem, operations may continue for an additional 2 hours without PAM monitoring as long as: • No marine mammals were detected by PAM in the mitigation zones in the previous 2 hours; • Two MMOs maintain watch at all times during operations when PAM is not operational; • The time and location in which operations began and stop without an active PAM system is recorded.	Abate on site

Vessel and Aircraft Operations

No.	Mitigation measure	Classification
1	Pre-plan flight paths to ensure that no flying occurs over seal colonies and seabird nesting areas.	Avoid / abate on site
2	Avoid extensive low-altitude coastal flights by ensuring that the flight path is perpendicular to the coast, as far as possible.	Avoid/ abate on site
3	Brief all pilots on the ecological risks associated with flying at a low level along the coast or above marine mammals.	Avoid
4	The lighting on the survey and support vessels should be reduced to a minimum compatible with safe operations wherever and wherever possible. Light sources should, if possible and consistent with safe working practices, be positioned in places where emissions to the surrounding environment can be minimised.	Reduce at Source

No.	Mitigation measure	Classification
5	Keep abornensated, but otherwise unharmed, seabirds in dark containers (e.g. cardboard box) for subsequent release during daylight hours. Ringed/banded birds should be reported to the appropriate ringing/banding scheme (details are provided on the ring).	Repair or Restore
6	Avoid the unnecessary discharge of ballast water.	Reduce at source
7	Use filtration procedures during loading in order to avoid the uptake of potentially harmful aquatic organisms, pathogens and sediment that may contain such organisms.	Avoid/reduce at source
8	Ensure that routine cleaning of ballast tanks to remove sediments is carried out, where practicable, in mid-ocean or under controlled arrangements in port or dry dock, in accordance with the provisions of the ship's Ballast Water Management Plan.	Avoid/reduce at source
9	Ensure all equipment (e.g. arrays, streamers, tail buoys etc) that has been used in other regions is thoroughly cleaned prior to deployment.	Avoid/Reduce at Source
10	Implement a waste management system that addresses all wastes generated at the various sites, shore-based and marine. This should include: – Separation of wastes at source; – Recycling and re-use of wastes where possible; – Treatment of wastes at source (maceration of food wastes, compaction, incineration, treatment of sewage and oily water separation).	Avoid/Reduce at Source
11	Implement leak detection and repair programmes for valves, flanges, fittings, seals, etc.	Avoid/Reduce at Source
12	Use a low-toxicity biodegradable detergent for the cleaning of all deck spillages.	Reduce at Source
13	The vessel operators should keep a constant watch for marine mammals and turtles in the path of the vessel.	Avoid
14	Keep watch for marine mammals behind the vessel when tension is lost on the towed equipment and either retrieve or regain tension on towed gear as rapidly as possible.	Avoid
15	Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'.	Avoid
16	Ensure vessel transit speed between the survey area and port is a maximum of 12 knots (22 km/hr), except in the MPA; where it is reduced further to 10 knots (18 km/hr).	Avoid/reduce at source
17	Ensuring that loads are lifted using the correct lifting procedure and within the maximum lifting capacity of crane system.	Avoid
18	Minimise the lifting path between vessels.	Avoid
19	Undertake frequent checks to ensure items and equipment are stored and secured safely on board each vessel.	Avoid
20	In the event that equipment is lost during the operational stage, assess safety and metocean conditions before performing any retrieval operations. Establishing a hazards database listing the type of gear left on the seabed and/or in the Reconnaissance Permit Area with the dates of abandonment/loss and locations, and where applicable, the dates of retrieval.	Repair/restore
21	Use low toxicity dispersants cautiously and only with the permission of the Department of Forestry, Fisheries and Environment (DFFE).	Abate on and off site

No.	Mitigation measure	Classification
22	As far as possible, and whenever the sea state permits, attempt to control and contain the spill at sea with suitable recovery techniques to reduce the spatial and temporal impact of the spill.	Abate on site
23	Ensure adequate resources are provided to collect and transport oiled birds to a cleaning station.	Restore
24	Ensure offshore bunkering is not undertake in the following circumstances: – Wind force and sea state conditions of ≥6 on the Beaufort Wind Scale; – During any workboat or mobilisation boat operations; – During helicopter operations; – During the transfer of in-sea equipment; and – At night or times of low visibility.	Avoid / Reduce at source

EXPERTISE AND DECLARATION OF INDEPENDENCE

This report was prepared by Dr Andrea Pulfrich of Pisces Environmental Services (Pty) Ltd. Andrea has a PhD in Fisheries Biology from the Institute for Marine Science at the Christian-Albrechts University, Kiel, Germany.

As Director of Pisces since 1998, Andrea has considerable experience in undertaking specialist environmental impact assessments, baseline and monitoring studies, and Environmental Management Programmes relating to marine diamond mining and dredging, hydrocarbon exploration and thermal/hypersaline effluents. She is a registered Environmental Assessment Practitioner and member of the South African Council for Natural Scientific Professions (Pr.Sci.Nat. No: 400327/06), South African Institute of Ecologists and Environmental Scientists, and International Association of Impact Assessment (South Africa).

This specialist report was compiled for EIMS (Pty) Ltd for their use in preparing a Basic Assessment Report and Environmental Management Programme Report (EMPr) for proposed 3D seismic acquisition in the Orange Basin off the West Coast of South Africa.

I do hereby declare that Pisces Environmental Services (Pty) Ltd is financially and otherwise independent of TGS Geophysical Company (UK) Ltd, and has no vested interests in the proposed project or the study area.

Andrea Pulfrich

Dr Andrea Pulfrich

1 GENERAL INTRODUCTION

Hydrocarbon deposits occur in reservoirs in sedimentary rock layers. Being lighter than water they accumulate in traps where the sedimentary layers are arched or tilted by folding or faulting of the geological layers. Marine seismic surveys are the primary tool for locating such deposits and are thus an indispensable component of offshore oil or gas exploration.

Seismic survey programmes comprise data acquisition in either two-dimensional (2D) and/or three dimensional (3D) scales, depending on information requirements. 2D surveys are typically applied to obtain regional data from widely spaced survey grids and provide a vertical slice through the seafloor geology along the survey track-line. Infill surveys on closer grids subsequently provide more detail over specific areas of interest. In contrast, 3D seismic surveys are conducted on a very tight survey grid, and provide a cube image of the seafloor geology along each survey track-line. Such surveys are typically applied to promising petroleum prospects to assist in fault line interpretation.

The nature of the sound impulses utilised during seismic surveys have resulted in concern over their potential impact on marine fauna, particularly marine mammals, seabirds and fish (McCauley et al. 2000). Consequently, it has been proposed that environmental management already be applied at the exploration stage of the life cycle of a hydrocarbon field project (Duff et al. 1997, in Salter & Ford 2001).

For this investigation TGS Geophysical Company (UK) Ltd (TGS) is planning to undertake 3D seismic acquisition in the Orange Basin off the West Coast of South Africa. The area of interest is located on the edge of the South African Exclusive Economic Zone (EEZ). Although the Reconnaissance Permit Area extends over a number of licence blocks between the South-African - Namibian border and Cape Columbine, the proposed 3D acquisition area is confined to the Deep Water Orange Basin Block. Water depths in the Reconnaissance Permit area range from -500 m to nearly 4 000 m. Environmental Impact Management Services (Pty) Ltd (EIMS) has been appointed byTGS to compile the Basic Assessment Report and Environmental Management Programme (EMP) for the proposed 3D seismic acquisition. EIMS in turn has approached Pisces Environmental Services (Pty) Ltd to provide a specialist report on potential impacts of the proposed seismic operations on biodiversity and ecosystem services in the area.

1.1 Scope of Work

This specialist report was compiled as a desktop study on behalf of TGS, for their use in preparing an EMP as part of a Basic Assessment Report for the proposed 3D seismic survey in the Orange Basin, offshore of the West Coast of South Africa.

The terms of reference specifically for the Biodiversity and Ecosystem Services Assessment are:

- Provide a general description of the marine ecosystem goods and services in the Benguela System along the South African West Coast, based on current available literature;
- Provide a qualitative and/or quantitative description of the Biodiversity and Ecosystem Services values occurring at the site, including their current condition, trends and uses.
- Describe the offshore habitats that are likely to be affected by seismic activities.
- Identify acoustically sensitive marine species (receptors).

- Confirm the presence and/or status of priority biodiversity features, habitats and species in the impact area, and contextualise the assessment within local, regional and national conservation priorities.
- Describe the significance of seasonality and natural cycles/variability of key marine fauna.
- Highlight the implications of gaps in information, uncertainty and/or risks in terms of irreversibility of impacts, irreplaceable loss of resource, etc.
- Assess whether there are any secondary, indirect, induced and/or cumulative impacts.
- Identify, describe and assess the significance of potential impacts of the proposed seismic survey on Biodiversity and Ecosystem Services.
- Systematically apply the Mitigation Hierarchy for avoidance and reduction of any negative impacts across all phases of the seismic survey.
- When making recommendations, specify and identify all mitigation with reference to the options in the Mitigation Hierarchy.

1.2 Approach to the Study

All identified marine and coastal impacts are summarised, categorised and ranked in an appropriate impact assessment table, to be incorporated in the overall EIA.

1.3 Assumptions, Limitations and Information Gaps

As determined by the terms of reference, this study has adopted a 'desktop' approach. Consequently, the description of the natural baseline environment in the study area is based on a review and collation of existing information and data from the scientific literature, internal reports and the Marine Mammal Observer (MMO) Reports. The sources consulted are listed in the Reference chapter.

The assumptions made in this specialist assessment are:

- The study is based on the project description made available to the specialist at the time of the commencement of the study.
- Some important conclusions regarding the extent of the zones of impact of seismic sound and associated assessments on marine fauna are based on the results of the Underwater Acoustic Modelling Study (SLR 2022).
- Potential changes in the marine environment such as sea-level rise and/or increases in the severity and frequency of storms related to climate change are not included in the terms of reference and therefore not dealt with in this report.

All identified marine impacts are summarised, categorised and ranked in appropriate impact assessment tables, to be incorporated in the overall EIA Report.

Information gaps include:

- details of the benthic macrofaunal communities beyond the shelf break;
- details on demersal fish communities beyond the shelf break;

- information specific to the marine communities of seamounts (Tripp Seamount, Child's Bank) and submarine canyons (Cape Canyon and Cape Point Canyon); and
- current information on the distribution, population sizes and trends of most cetacean species occurring in South African waters and the project area in particular.

Keeping these information gaps in mind, the assessment of impacts has adopted a strongly precautionary approach.

1.4 Assessment Procedure

The assessment convention used by Environmental Impact Management Services (Pty) Ltd (EIMS), who are undertaking the Reconnaissance Permit Application and compiling the Basic Assessment Report for TGS, was used to determine significance ratings in the assessment (see Appendix 1).

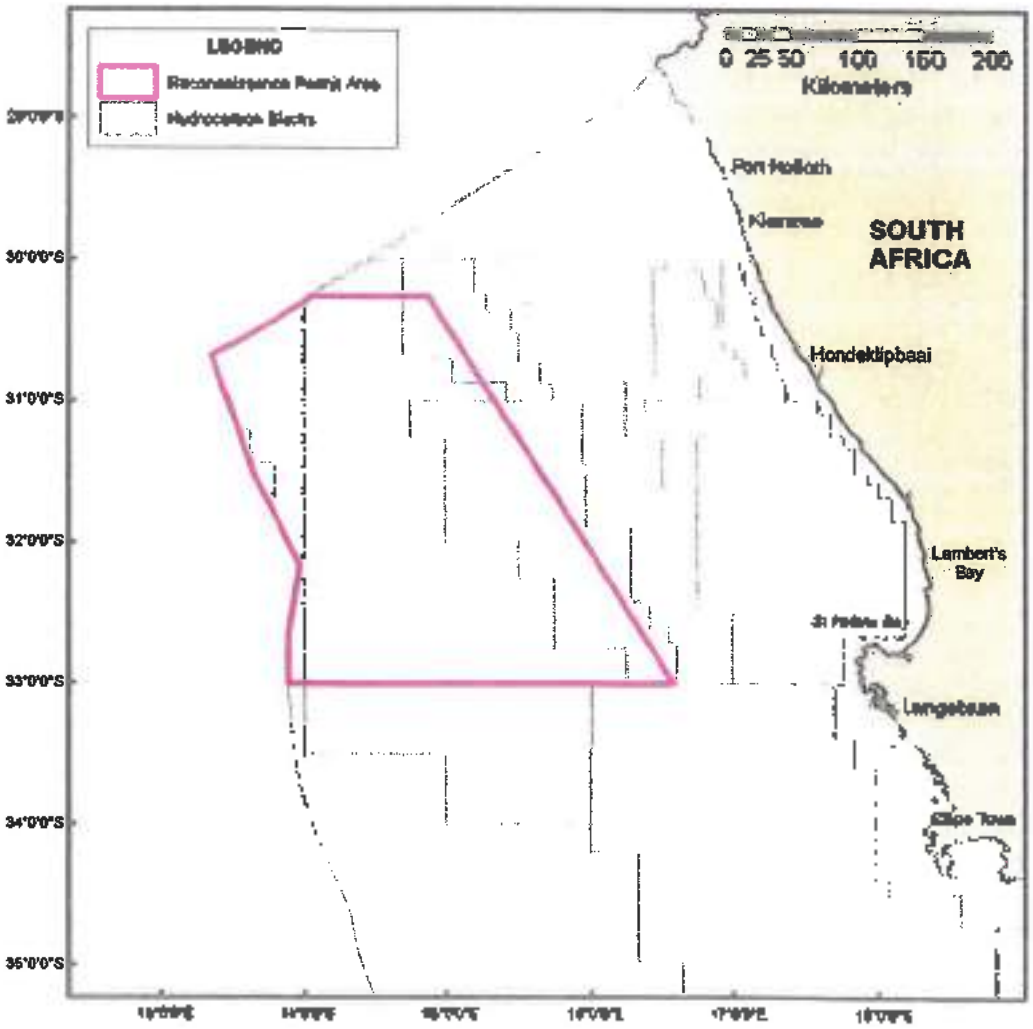

Figure 1: Map of the proposed Reconnaissance Permit Area (red polygon) in relation to hydrocarbon blocks off the West Coast (grey polygons).

2 DESCRIPTION OF THE PROPOSED PROJECT

TGS Geophysical Company (UK) Ltd is planning to conduct a seismic campaign over in the Orange Basin during the best available window of opportunity in either 2023 or 2024, subject to granting of the Reconnaissance PermR and vessel availability. The Reconnaissance Permit Area is approximately 57 400 km² in extent. Water depths in the Reconnaissance Permit Area range from ~500 m to nearly 4 000 m. The area is situated roughly between the Orange River mouth and Cape Columbine, approximately 120 km offshore at its closest points. The total 3D survey duration would be in the order of up to 70 days.

The anticipated acoustic source (airgun) and hydrophone array would consist of 24 active guns with operating pressures of 2 000 pound-force per square inch (psi), situated some 50 m behind the vessel at a depth of 7 - 8 m below the surface. The 3D survey will involve multiple streamers (up to 12 streamers spaced 100 m apart) up to 12 000 m long, towed at a depth of approximately 8 m.

The seismic vessel would steam a series of predefined transects describing the survey grid, the headings of which would be fixed and reciprocal. During surveying the seismic vessel would travel at a speed of between four and six knots and the sound sources would be "fired" by the airgun array. As the seismic vessel would be restricted in manoeuvrability (a turn radius of approximately 5 km is expected), other vessels should remain clear of it. A support vessel usually assists in the operation of keeping other vessels at a safe distance.

Each triggering of a sound pulse is termed a seismic shot, and these are fired at intervals of 6 - 20 seconds (depending on water depth and other environmental characteristics) (Barger & Hamblen 1980). Each seismic shot is usually only between 5 and 30 milliseconds in duration, and despite peak levels within each shot being high, the total energy delivered into the water is low.

Airguns have most of their energy in the 5-300 Hz frequency range, with the optimal frequency required for deep penetration seismic work being 50-80 Hz.

Sound levels from individual airguns use today in the seismic industry range from 200 to 232 dB re 1 µPa at 1 m, for small to large individual guns, respectively. For airgun arrays, sound levels range from 235 dB re 1 µPa at 1 m for a small array (500 cubic inches) to 260 dB re 1 µPa at 1 m for large arrays (7 900 cubic inches) (Bröcker 2019). The majority of the produced energy is below 250 Hz, with 90% of the energy between 70 to 140 Hz, although pulses do contain some higher frequencies up to 16 kHz (Bröcker 2019). It must be noted, however, that the sound level specifications for airgun arrays refer to sound levels in the vertical direction directly beneath the airgun array, generally near its centre, with nominal sound levels in the horizontal direction being ~10-20 dB lower (Caldwell & Dragoset 2000; Dragoset 2000).

5928

3 DESCRIPTION OF THE BASELINE MARINE ENVIRONMENT

The descriptions of the physical and biological environments along the South African West Coast focus primarily on the study area between the Orange River mouth and Cape Point. The description of the marine environment includes the various biophysical receptors that may be affected both directly and indirectly by the project activities. The area of direct influence would include those receptors located within or immediately adjacent to the area of interest for seismic acquisition within the Orange Basin, which may be affected by seismic noise, whereas the area of indirect influence will vary in extent depending on the type of receptor potentially affected by more far-reaching impacts. The summaries presented below are based on information gleaned from Lane & Carter (1999), Morant (2006), and Penney *et al.* (2007), supplemented with more recent information available in peer-reviewed publications and internal reports. Natasha Karenyi of the University of Cape Town contributed to a previous version of the description of benthic macrofaunal communities. Dr Simon Elwen of the Namibian Dolphin Project and Mammal Research Institute (University of Pretoria) provided input into a previous version of the section on marine mammals.

3.1 Geophysical Characteristics

3.1.1 Bathymetry

The continental shelf along the West Coast is generally wide and deep, although large variations in both depth and width occur. The shelf maintains a general NNW trend, widening north of Cape Columbine and reaching its widest off the Orange River (180 km) (see Figure 2). The nature of the shelf break varies off the South African West Coast. Between Cape Columbine and the Orange River, there is usually a double shelf break, with the distinct inner and outer slopes, separated by a gently sloping ledge. The immediate inshore[1] area consists mainly of a narrow (about 8 km wide) rugged rocky zone and slopes steeply seawards to a depth of around 80 m. The middle (-50 to -150 m) and outer shelf (-150 to -350 m) normally lacks relief and slopes gently seawards reaching the shelf edge at a depth of between -350 to -500 m (Sink *et al.* 2019). The three shelf zones characterising the West Coast are recognised following both abiotic (de Wet 2013) and biotic (Karenyi *et al.* 2016) patterns.

Banks on the continental shelf include the Orange Bank (Shelf or Cone), a shallow (160 - 190 m) zone that reaches maximal widths (180 km) offshore of the Orange River, and Child's Bank, situated ~350 km offshore at about 31°S, and within the northern portion of the project target area. Child's Bank is a major feature on the West Coast margin and is the only known submarine bank within South Africa's Exclusive Economic Zone (EEZ), rising from a depth of 350 - 400 m water to less than -200 m at its shallowest point. It is a rounded, flat topped, sandy plateau, which lies at the edge of the continental shelf. The bank has a gentle northern, eastern and southern margin but a steep, slump-generated outer face (Birch & Rogers 1973; Dingle *et al.* 1983; de Wet 2013). At its southwestern edge, the continental slope drops down steeply from -350 to -1 500 m over a distance of less than 60 km (de Wet 2013) creating precipitous cliffs at least 150 m high (Birch & Rogers 1973). The bank consists of resistant, horizontal beds of Pliocene sediments, similar to that of the Orange Banks, and

[1] As per the 2019 National Biodiversity Assessment inshore is defined as the area influenced by wave energy and light, with the fair weather wave base at a depth ranging between -30 to -50 m used to determine the outer limits of this zone in South Africa. Offshore areas are those that extend beyond this zone.

JH23

represents another perched erosional outlier formed by Post-Pliocene erosion (Dingle 1973; Siesser *et al.* 1974). The top of this feature, has been estimated to cover some 1 450 km^2 (Sink *et al.* 2012).

Tripp Seamount, a geological feature ~25 km to the north of the Reconnaissance Permit area, rises from the seabed at ~1 000 m to a depth of 150 m. It is a roughly circular feature with a flat apex that drops steeply on all sides.

Further underwater features in the vicinity of the Reconnaissance Permit Area include the Cape Canyon and Cape Point Valley, which lie ~95 km and ~250 km to the southeast of the southern boundary of the Reconnaissance Permit Area (Simpson & Forder 1968; Dingle 1986; Wigley 2004; Wigley & Compton 2006). The Cape Canyon was discovered in the 1960s. The canyon head forms a well-developed trench on the continental shelf, 100 m deep and 4 km wide (Wigley 2004; Wigley & Compton 2006). South of Cape Columbine the canyon becomes progressively narrower and deeper. Adjacent to Cape Town in a water depth of 1 500 m, the canyon has a local relief in the order of 500-800 m (Simpson & Forder 1968; Dingle *et al.* 1987). The Cape Canyon has a longitudinal extent of at least 200 km and can be traced to a water depth of at least 3 600 m (Dingle 1970), where the topography of the distal end is rugged and complex (Dingle *et al.* 1987). Sediments in the canyon are predominately unconsolidated sands and muds. The canyon serves as an upwelling feature funnelling cold, nutrient-rich South Atlantic Central Water up the canyon slope providing highly productive surface waters which in turn power feeding grounds for cetaceans and seabirds (Filander *et al.* 2018; www.environment.gov.za/ dearesearchteamreturnfromdeepseaexpedition).

The Cape Point Valley, which lies about 70 km south of the Cape Peninsula, is another large canyon breaching the shelf. This canyon has sustained the highest fishing effort and catches in the South African demersal trawl fishery for almost a century (www.marineprotectedareas.org.za/canyons).

Using high-resolution bathymetry collected between 315 - 3 125 m depth, Palan (2017) identified numerous new and previously undocumented submarine canyon systems, most of which are less extensive than the Cape Canyon and Cape Point Valley and do not incise the shelf (Figure 3). Canyon morphology was highly variable and included linear, sinuous, hooked and shelf-indenting types. Large fluid seep/pockmark fields of varying morphologies were similarly revealed situated in close proximity to the sinuous, hooked and shelf-indenting canyon types thereby providing the first evidence of seafloor fluid venting and escape features from the South African margin. These pockmarks represent the terminus of stratigraphic fluid migration from an Aptian gas reservoir, evidenced in the form of blowout pipes and brightened reflectors. This area lies well to the southeast of the Reconnaissance Permit Area.

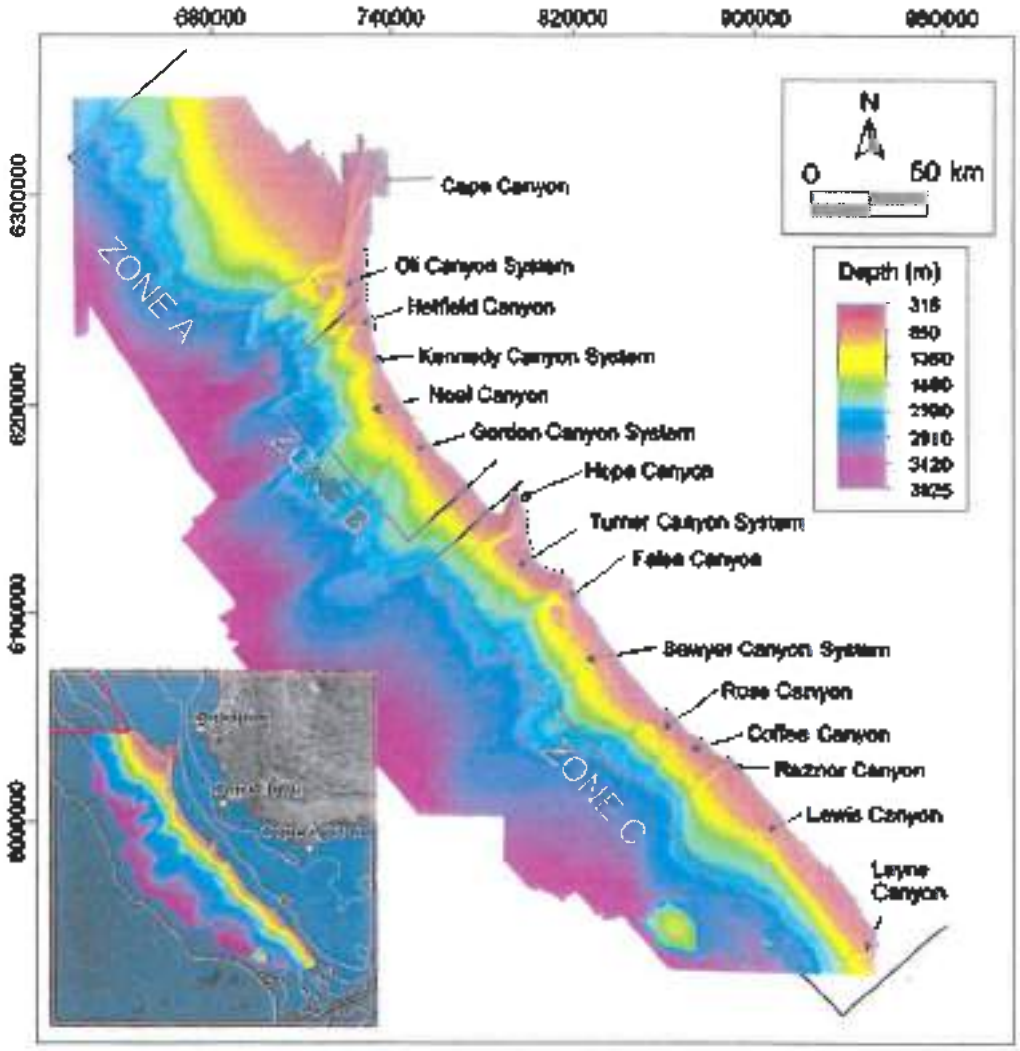

Figure 3: Submarine canyon domains of the southwestern Cape continental margin identified by Paton (2017). Insert shows the locality of the study area (red polygon) in relation to the canyons.

3.1.2 Coastal and Inner-shelf Geology and Seabed Geomorphology

Figure 4 illustrates the distribution of seabed surface sediment types off the South African north-western coast. The inner shelf is underlain by Precambrian bedrock (Pre-Mesozoic basement), whilst the middle and outer shelf areas are composed of Cretaceous and Tertiary sediments (Dingle 1973; Dingle *et al.* 1987; Birch *et al.* 1976; Rogers 1977; Rogers & Bremner 1991). As a result of erosion on the continental shelf, the unconsolidated sediment cover is generally thin, often less than 1 m. Sediments are finer seawards, changing from sand on the inner and outer shelves to muddy sand and sandy mud in deeper water. However, this general pattern has been modified considerably by biological deposition (large areas of shelf sediments contain high levels of calcium carbonate) and localised river input. An ~500-km long mud belt (up to 40 km wide, and of 15 m average thickness) is situated over the inner shelf between the Orange River and St Helena Bay (Birch *et al.* 1976). Further offshore and within the Reconnaissance Permit Area, sediment is dominated by muds and

sandy muds. The continental slope, seaward of the shelf break, has a smooth seafloor, underlain by calcareous ooze.

Present day sedimentation is limited to input from the Orange River. This sediment is generally transported northward. Most of the sediment in the area is therefore considered to be relict deposits by now ephemeral rivers active during wetter climates in the past. The Orange River, when in flood, still contributes largely to the mud belt as suspended sediment is carried southward by poleward flow. In this context, the absence of large sediment bodies on the inner shelf reflects on the paucity of terrigenous sediment being introduced by the few rivers that presently drain the South African West Coast coastal plain.

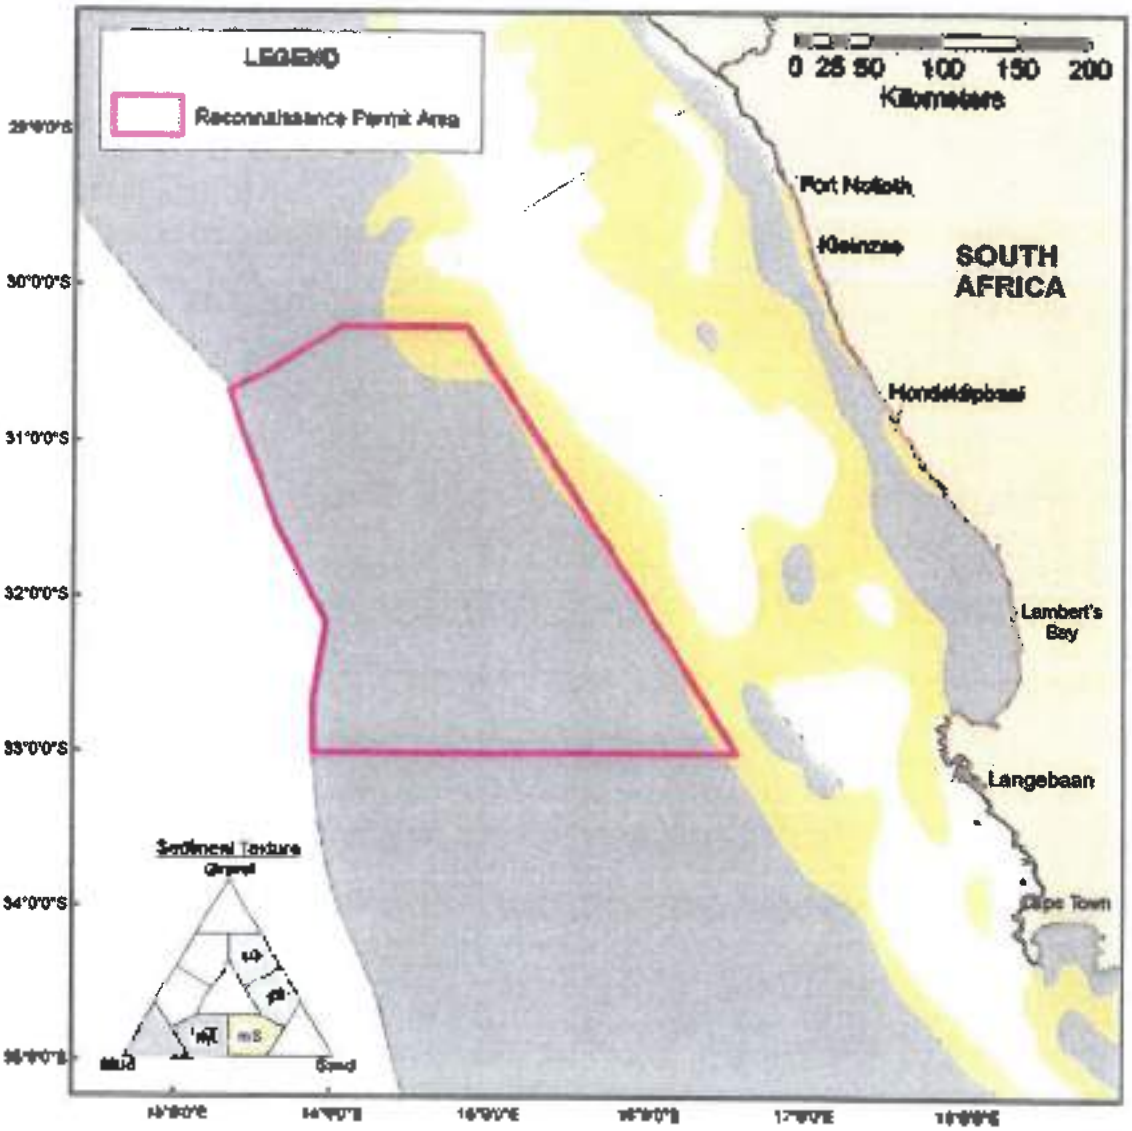

Figure 4: The Reconnaissance Permit Area in relation to sediment distribution on the continental shelf of the South African West Coast (Adapted from Rogers 1977). Based on information in Holness *et al.* (2014) and Sink *et al.* (2019), the mud/sandy mud sediments have been extended to the edge of the EEZ beyond that shown in Rogers (1977).

The benthic habitat types of the West Coast were classified and mapped in detail through the 2011 National Biodiversity Assessment (NBA) (Sink *et al.* 2012a). These were refined in the 2018 NBA (Sink *et al.* 2019) to provide substratum types (Figure 5).

In the Reconnaissance Permit Area the water depth ranges from -500 m to nearly 4 000 m. The Southeast Atlantic Unclassified Slopes and Southeast Atlantic Unclassified Abyss substrata dominate across the area. The shelf inshore of the Reconnaissance Permit Area boasts a diversity of substrata (Sink *et al.* 2019).

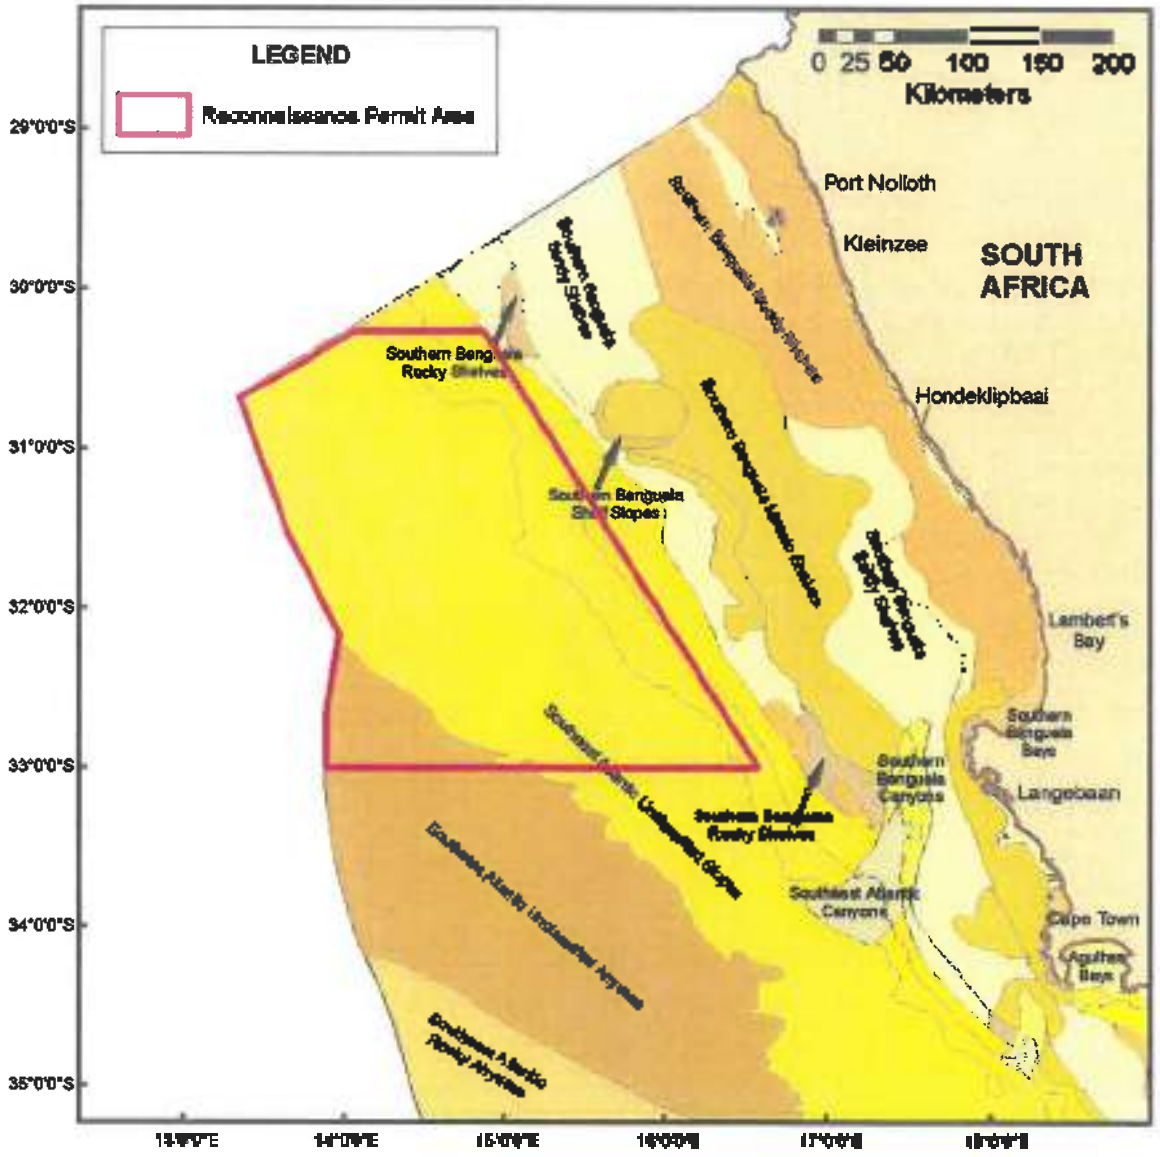

Figure 5: The Reconnaissance Permit Area in relation to the distribution of seabed substratum types along the West Coast (adapted from Sink *et al.* 2019).

3.2 Biophysical Characteristics

3.2.1 Wind Patterns

Winds are one of the main physical drivers of the nearshore Benguela region, both on an oceanic scale, generating the heavy and consistent south-westerly swells that impact this coast, and locally, contributing to the northward-flowing longshore currents, and being the prime mover of sediments in the terrestrial environment. Consequently, physical processes are characterised by the average seasonal wind patterns, and substantial episodic changes in these wind patterns have strong effects on the entire Benguela region.

The prevailing winds in the Benguela region are controlled by the South Atlantic subtropical anticyclone, the eastward moving mid-latitude cyclones south of southern Africa, and the seasonal atmospheric pressure field over the subcontinent. The south Atlantic anticyclone is a perennial feature that forms part of a discontinuous belt of high-pressure systems which encircle the subtropical southern hemisphere. This undergoes seasonal variations, being strongest in the austral summer, when it also attains its southernmost extension, lying south west and south of the subcontinent. In winter, the south Atlantic anticyclone weakens and migrates north-westwards.

These seasonal changes result in substantial differences between the typical summer and winter wind patterns in the region, as the southern hemisphere anti-cyclonic high-pressures system, and the associated series of cold fronts, moves northwards in winter, and southwards in summer. The strongest winds occur in summer (October to March), during which winds blow 98% of the time (PRDW 2013), with a total of 226 gales (winds exceeding 18 m/s or 35 kts) being recorded over the period (CSIR 2006). Virtually all winds in summer come from the south to south-southeast (Figure 6). These southerlies occur over 40% of the time, averaging 20 - 30 kts and reaching speeds in excess of 60 kts, bringing cool, moist air into the coastal region and driving the massive offshore movements of surface water, and the resultant strong upwelling of nutrient-rich bottom waters, which characterise this region in summer. The winds also play an important role in the loss of sediment from beaches. These strong equatorwards winds are interrupted by the passing of coastal lows with which are associated periods of calm or north or northwest wind conditions. These northerlies occur throughout the year, but are more frequent in winter.

Winter remains dominated by southerly to south-easterly winds, but the closer proximity of the winter cold-front systems results in a significant south-westerly to north-westerly component (Figure 6). This 'reversal' from the summer condition results in cessation of upwelling, movement of warmer mid-Atlantic water shorewards and breakdown of the strong thermoclines which typically develop in summer. There are also more calms in winter, occurring about 3% of the time, and wind speeds generally do not reach the maximum speeds of summer. However, the westerly winds blow in synchrony with the prevailing south-westerly swell direction, resulting in heavier swell conditions in winter.

During autumn and winter, catabatic, or easterly 'berg' winds can also occur. These powerful offshore winds can exceed 50 km/h, producing sandstorms that considerably reduce visibility at sea and on land. Although they occur intermittently for about a week at a time, they have a strong effect on the coastal temperatures, which often exceed 30°C during 'berg' wind periods (Shannon & O'Toole 1998). The winds also play a significant role in sediment input into the coastal marine environment with transport of the sediments up to 150 km offshore.

5028

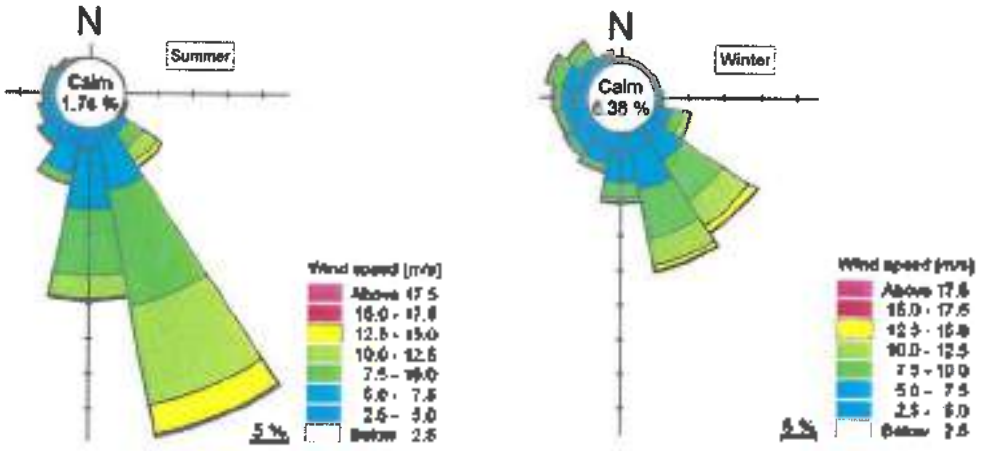

Figure 6: Wind Speed vs. Wind Direction for NCEP hind cast data at location 15°E, 31°S (From PRDW 2013).

3.2.2 Large-Scale Circulation and Coastal Currents

The southern African West Coast is strongly influenced by the Benguela Current. Current velocities in continental shelf areas generally range between 10-30 cm/s (Boyd & Oberholster 1994), although localised flows in excess of 50 cm/s occur associated with eddies (PRDW 2013). On its western side, flow is more transient and characterised by large eddies shed from the retroflection of the Agulhas Current. This results in considerable variation in current speed and direction over the domain (PRDW 2013). In the south the Benguela current has a width of 200 km, widening rapidly northwards to 750 km. The surface flows are predominantly wind-forced, barotropic and fluctuate between poleward and equatorward flow (Shillington *et al.* 1990; Nelson & Hutchings 1983) (Figure 7b). Fluctuation periods of these flows are 3 - 10 days, although the long-term mean current residual is in an approximate northwest (alongshore) direction. Current speeds decrease with depth, while directions rotate from predominantly north-westerly at the surface to south-easterly near the seabed. Near bottom shelf flow is mainly poleward with low velocities of typically <5 cm/s (Nelson 1989; PRDW 2013). The poleward flow becomes more consistent in the southern Benguela.

The major feature of the Benguela Current is coastal upwelling and the consequent high nutrient supply to surface waters leads to high biological production and large fish stocks. The prevailing longshore, equatorward winds move nearshore surface water northwards and offshore. To balance the displaced water, cold, deeper water wells up inshore. Although the rate and intensity of upwelling fluctuates with seasonal variations in wind patterns, the most intense upwelling tends to occur where the shelf is narrowest and the wind strongest. There are three upwelling centres in the southern Benguela, namely the Namaqua (30°S), Cape Columbine (33°S) and Cape Point (34°S) upwelling cells (Taunton-Clark 1985) (Figure 7a). Upwelling in these cells is seasonal, with maximum upwelling occurring between September and March. Both the Reconnaissance Permit area and the proposed 3D survey area are located offshore of these upwelling events.

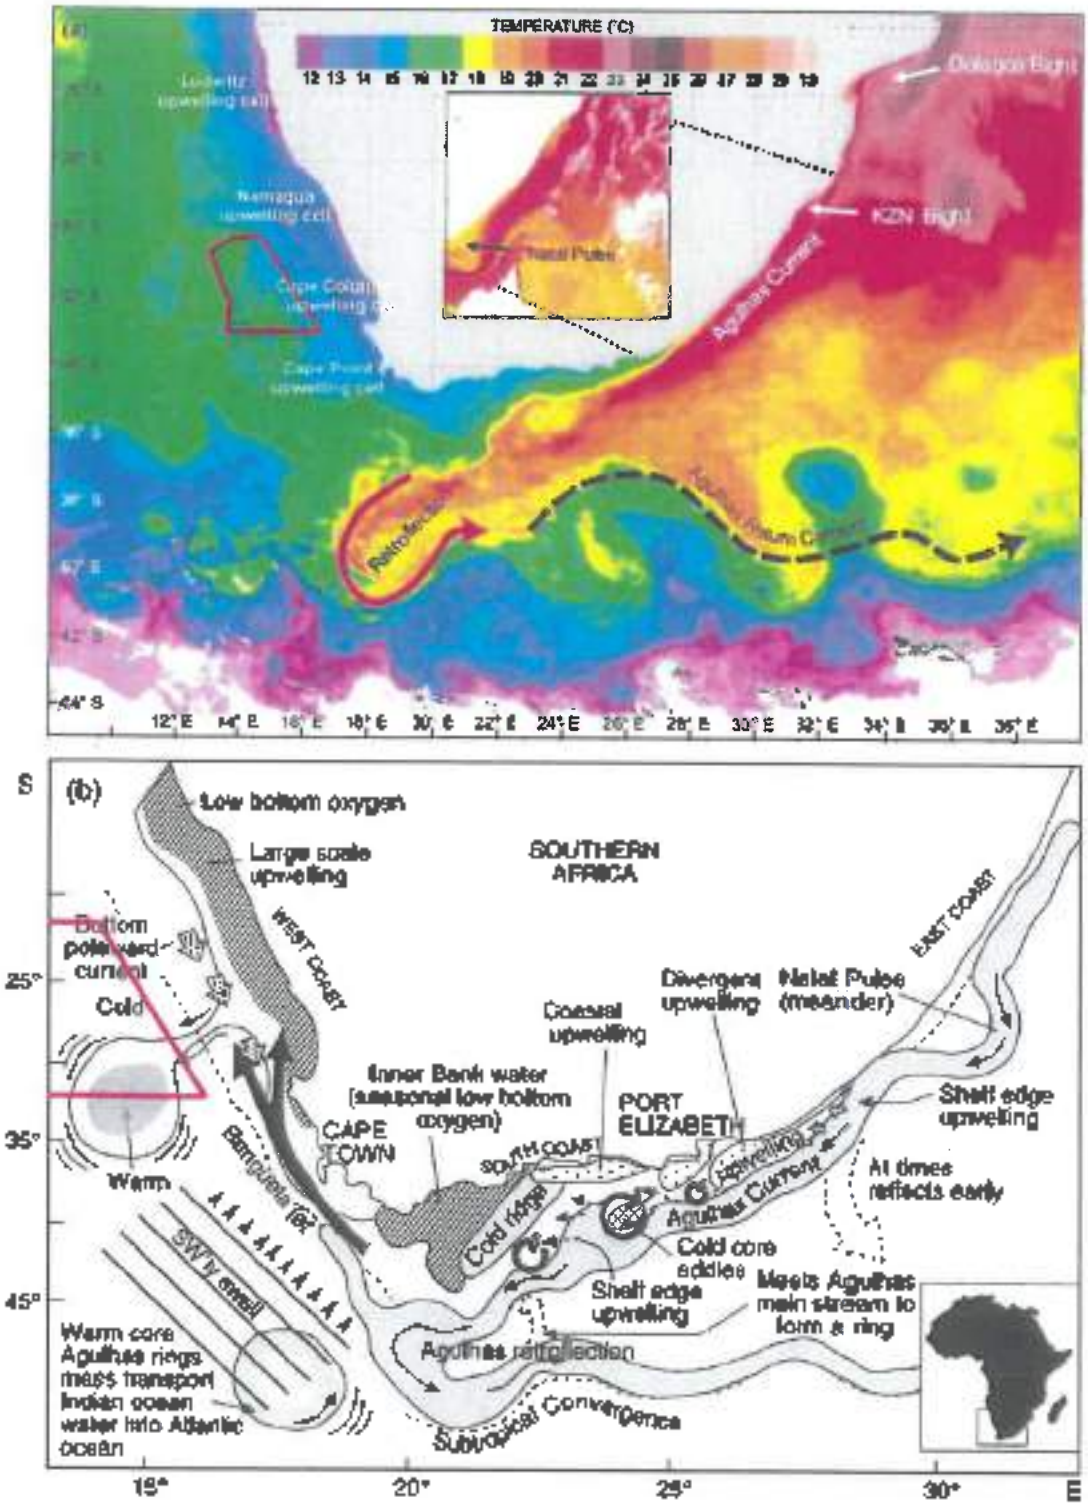

Figure 7: (a) Satellite sea-surface temperature image showing the predominance of the warm Agulhas Current along the South African south coast and the colder upwelled water on the west coast (adapted from Roberts *et al.* 2010), and (b) physical processes and features associated with the Southwest Coast (adapted from Roberts 2005) in relation to the Reconnaissance Permit Area (red polygon).

Where the Agulhas Current passes the southern tip of the Agulhas Bank (Agulhas Retroflection area), it may shed a filament of warm surface water that moves north-westward along the shelf edge towards Cape Point, and Agulhas Rings, which similarly move north-westwards into the South Atlantic Ocean (Figure 7). These rings may extend to the seafloor and west of Cape Town may split, disperse or join with other rings. During the process of ring formation, intrusions of cold subantarctic water moves into the South Atlantic. The contrast in warm (nutrient-poor) and cold (nutrient-rich) water is thought to be reflected in the presence of cetaceans and large migratory pelagic fish species (Best 2007). The Reconnaissance Permit Area lies offshore of 15°E on the outer edge of these features.

3.2.3 Waves and Tides

Most of the west coast of southern Africa is classified as exposed, experiencing strong wave action, rating between 13-17 on the 20 point exposure scale (McLachlan 1980). Much of the coastline is therefore impacted by heavy south-westerly swells generated in the roaring forties, as well as significant sea waves generated locally by the prevailing moderate to strong southerly winds characteristic of the region (Figure 8). The peak wave energy periods fall in the range 9,7 - 15,5 seconds.

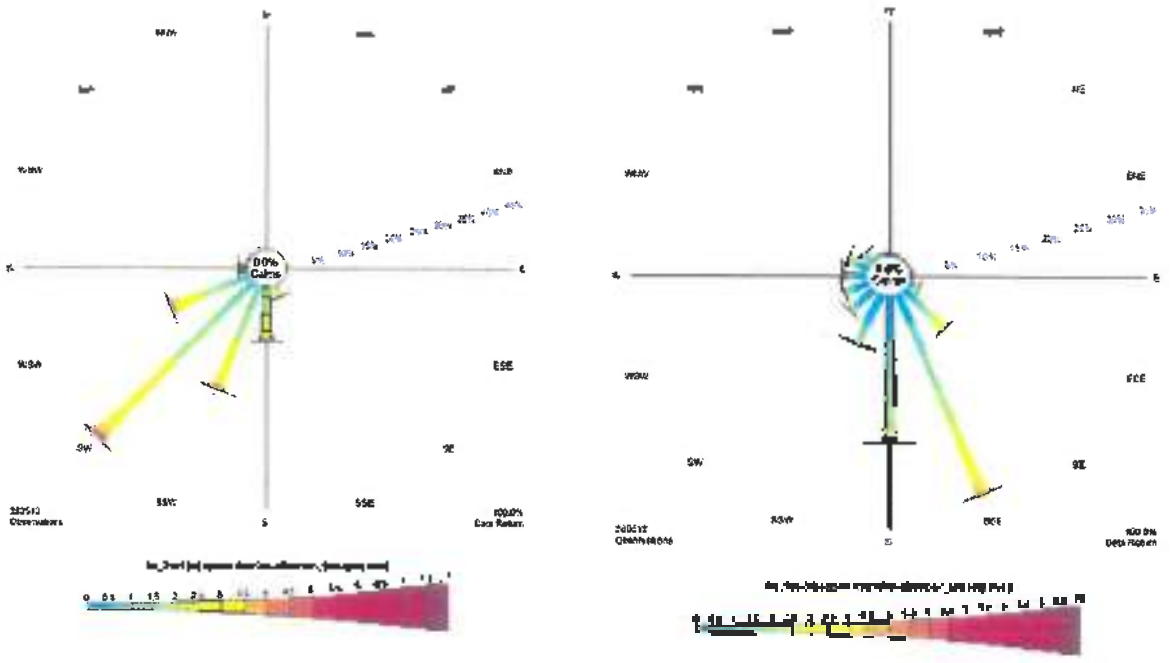

Figure 8: Annual roseplots of significant wave height partitions of swell (left) and wind-sea (right) for GROW1012 hind cast data at location 15°E, 31°S.

The wave regime along the southern African west coast shows only moderate seasonal variation in direction, with virtually all swells throughout the year coming from the S and SSW direction. Winter swells are strongly dominated by those from the S and SSW, which occur almost 80% of the time, and typically exceed 2 m in height, averaging about 3 m, and often attaining over 5 m. With wind speeds

capable of reaching 100 km/h during heavy winter south-westerly storms, winter swell heights can exceed 10 m.

In comparison, summer swells tend to be smaller on average, typically around 2 m, not reaching the maximum swell heights of winter. There is also a slightly more pronounced southerly swell component in summer. These southerly swells tend to be wind-induced, with shorter wave periods (~8 seconds), and are generally steeper than swell waves (CSIR 1996). These wind-induced southerly waves are relatively local and, although less powerful, tend to work together with the strong southerly winds of summer to cause the northward-flowing nearshore surface currents, and result in substantial nearshore sediment mobilisation, and northwards transport, by the combined action of currents, wind and waves.

In common with the rest of the southern African coast, tides are semi-diurnal, with a total range of some 1.5 m at spring tide, but only 0.6 m during neap tide periods.

3.2.4 Water

South Atlantic Central Water (SACW) comprises the bulk of the seawater in the study area, either in its pure form in the deeper regions, or mixed with previously upwelled water of the same origin on the continental shelf (Nelson & Hutchings 1983). Salinities range between 34.5‰ and 35.5‰ (Shannon 1985).

Seawater temperatures on the continental shelf of the southern Benguela typically vary between 6°C and 16°C. Well-developed thermal fronts exist, demarcating the seaward boundary of the upwelled water. Upwelling filaments are characteristic of these offshore thermal fronts, occurring as surface streamers of cold water, typically 50 km wide and extending beyond the normal offshore extent of the upwelling cell. Such fronts typically have a lifespan of a few days to a few weeks, with the filamentous mixing area extending up to 625 km offshore. South and east of Cape Agulhas, the Agulhas retroflection area is a global "hot spot" in terms of temperature variability and water movements.

The continental shelf waters of the Benguela system are characterised by low oxygen concentrations, especially on the bottom. SACW itself has depressed oxygen concentrations (~80% saturation value), but lower oxygen concentrations (<40% saturation) frequently occur (Bailey *et al.* 1985; Chapman & Shannon 1985).

Nutrient concentrations of upwelled water of the Benguela system attain 20 µM nitrate-nitrogen, 1.5 µM phosphate and 15-20 µM silicate, indicating nutrient enrichment (Chapman & Shannon 1985). This is mediated by nutrient regeneration from biogenic material in the sediments (Bailey *et al.* 1985). Modification of these peak concentrations depends upon phytoplankton uptake, which varies according to phytoplankton biomass and production rate. The range of nutrient concentrations can thus be large but, in general, concentrations are high.

3.2.5 Upwelling & Plankton Production

The cold, upwelled water is rich in inorganic nutrients, the major contributors being various forms of nitrates, phosphates and silicates (Chapman & Shannon 1985). During upwelling the comparatively nutrient-poor surface waters are displaced by enriched deep water, supporting substantial seasonal primary phytoplankton production. This, in turn, serves as the basis for a rich food chain up through

zooplankton, pelagic baitfish (anchovy, pilchard, round-herring and others), to predatory fish (hake and snoek), mammals (primarily seals and dolphins) and seabirds (jackass penguins, cormorants, pelicans, terns and others). High phytoplankton productivity in the upper layers again depletes the nutrients in these surface waters. This results in a wind-related cycle of plankton production, mortality, sinking of plankton detritus and eventual nutrient re-enrichment occurring below the thermocline as the phytoplankton decays. The eastern boundary of the Reconnaissance Permit Area is located on the western edge of these upwelling events and although waters are expected to be comparatively warm and nutrient poor, seasonal upwelling inshore of the Reconnaissance Permit Area can be expected (see Figure 7). The proposed 3D survey area is located well offshore of these upwelling events.

3.2.6 Organic Inputs

The Benguela upwelling region is an area of particularly high natural productivity, with extremely high seasonal production of phytoplankton and zooplankton. These plankton blooms in turn serve as the basis for a rich food chain up through pelagic baitfish (anchovy, pilchard, round-herring and others), to predatory fish (snoek), mammals (primarily seals and dolphins) and seabirds (jackass penguins, cormorants, pelicans, terns and others). All of these species are subject to natural mortality, and a proportion of the annual production of all these trophic levels, particularly the plankton communities, die naturally and sink to the seabed.

Balanced multispecies ecosystem models have estimated that during the 1990s the Benguela region supported biomasses of 76,9 tons/km^2 of phytoplankton and 31.5 tons/km^2 of zooplankton alone (Shannon *et al.* 2003). Thirty six percent of the phytoplankton and 5% of the zooplankton are estimated to be lost to the seabed annually. This natural annual input of millions of tons of organic material onto the seabed off the southern African West Coast has a substantial effect on the ecosystems of the Benguela region. It provides most of the food requirements of the particulate and filter-feeding benthic communities that inhabit the sandy-muds of this area, and results in the high organic content of the muds in the region. As most of the organic detritus is not directly consumed, it enters the seabed decomposition cycle, resulting in subsequent depletion of oxygen in deeper waters.

An associated phenomenon ubiquitous to the Benguela system are red tides (dinoflagellate and/or ciliate blooms) (see Shannon & Pillar 1985; Pitcher 1998). Also referred to as Harmful Algal Blooms (HABs), these red tides can reach very large proportions, extending over several square kilometres of ocean. Toxic dinoflagellate species can cause extensive mortalities of fish and shellfish through direct poisoning, while degradation of organic-rich material derived from both toxic and non-toxic blooms results in oxygen depletion of subsurface water. Being associated primarily with upwelling cells, HABs may occur in inshore of the Reconnaissance Permit Area, but would not be expected in the proposed 3D survey area.

3.2.7 Low Oxygen Events

The continental shelf waters of the Benguela system are characterised by low oxygen concentrations with <40% saturation occurring frequently (e.g. Visser 1969; Bailey *et al.* 1985). The low oxygen concentrations are attributed to nutrient remineralisation in the bottom waters of the system (Chapman & Shannon 1985). The absolute rate of this is dependent upon the net organic material

build-up in the sediments, with the carbon rich mud deposits playing an important role. As the mud on the shelf is distributed in discrete patches (see Figure 4), there are corresponding preferential areas for the formation of oxygen-poor water. The two main areas of low-oxygen water formation in the southern Benguela region are in the Orange River Bight and St Helena Bay (Chapman & Shannon 1985; Bailey 1991; Shannon & O'Toole 1998; Bailey 1999; Fossing *et al.* 2000). The spatial distribution of oxygen-poor water in each of the areas is subject to short- and medium-term variability in the volume of hypoxic water that develops. De Decker (1970) showed that the occurrence of low oxygen water off Lambert's Bay is seasonal, with highest development in summer/autumn. Bailey & Chapman (1991), on the other hand, demonstrated that in the St Helena Bay area daily variability exists as a result of downward flux of oxygen through thermoclines and short-term variations in upwelling intensity. Subsequent upwelling processes can move this low-oxygen water up onto the inner shelf, and into nearshore waters, often with devastating effects on marine communities.

Periodic low oxygen events in the nearshore region can have catastrophic effects on the marine communities leading to large-scale stranding of rock lobsters, and mass mortalities of marine biota and fish (Newman & Pollock 1974; Matthews & Pitcher 1996; Pitcher 1998; Cockcroft *et al.* 2000). The development of anoxic conditions as a result of the decomposition of huge amounts of organic matter generated by phytoplankton blooms is the main cause for these mortalities and walkouts. The most recent walkout occurred in early March 2022 at Elands Bay, when some 500 tons of rocklobster were reported stranded on the beach. The blooms develop over a period of unusually calm wind conditions when sea surface temperatures where high. Algal blooms usually occur during summer-autumn (February to April) but can also develop in winter during the 'berg' wind periods, when similar warm windless conditions occur for extended periods.

3.2.8 Turbidity

Turbidity is a measure of the degree to which the water loses its transparency due to the presence of suspended particulate matter. Total Suspended Particulate Matter (TSPM) can be divided into Particulate Organic Matter (POM) and Particulate Inorganic Matter (PIM), the ratios between them varying considerably. The POM usually consists of detritus, bacteria, phytoplankton and zooplankton, and serves as a source of food for filter-feeders. Seasonal microphyte production associated with upwelling events will play an important role in determining the concentrations of POM in coastal waters. PIM, on the other hand, is primarily of geological origin consisting of fine sands, silts and clays. Off Namaqualand, the PIM loading in nearshore waters is strongly related to natural inputs from the Orange River or from 'berg' wind events. Although highly variable, annual discharge rates of sediments by the Orange River is estimated to vary from 8 - 26 million tons/yr (Rogers 1979). 'Berg' wind events can potentially contribute the same order of magnitude of sediment input as the annual estimated input of sediment by the Orange River (Shannon & Anderson 1982; Zoutendyk 1992, 1995; Shannon & O'Toole 1998; Lane & Carter 1999). For example, a 'berg' wind event in May 1979 described by Shannon and Anderson (1982) was estimated to have transported in the order of 50 million tons of sand out to sea, affecting an area of 20 000 km^2.

Concentrations of suspended particulate matter in shallow coastal waters can vary both spatially and temporally, typically ranging from a few mg/ℓ to several tens of mg/ℓ (Bricel & Maloud 1984; Berg & Newell 1986; Fegley *et al.* 1992). Field measurements of TSPM and PIM concentrations in the Benguela current system have indicated that outside of major flood events, background concentrations of coastal and continental shelf suspended sediments are generally <12 mg/ℓ, showing significant long-

JC23

shore variation (Zoutendyk 1995). Considerably higher concentrations of PIM have, however, been reported from southern African West Coast waters under stronger wave conditions associated with high tides and storms, or under flood conditions. In the vicinity of the Orange River mouth, where river outflow strongly influences the turbidity of coastal waters, measured concentrations ranged from 14.3 mg/ℓ at Alexander Bay just south of the mouth (Zoutendyk 1995) to peak values of 7 400 mg/ℓ immediately upstream of the river mouth during the 1988 Orange River flood (Bremner *et al.* 1990).

The major source of turbidity in the swell-influenced nearshore areas off the West Coast is the redistribution of fine inner shelf sediments by long-period Southern Ocean swells. The current velocities typical of the Benguela (10-30 cm/s) are capable of resuspending and transporting considerable quantities of sediment equatorwards. Under relatively calm wind conditions, however, much of the suspended fraction (silt and clay) that remains in suspension for longer periods becomes entrained in the slow poleward undercurrent (Shillington *et al.* 1990; Rogers & Bremner 1991).

Superimposed on the suspended fine fraction, is the northward littoral drift of coarser bedload sediments, parallel to the coastline. This northward, nearshore transport is generated by the predominantly south-westerly swell and wind-induced waves. Longshore sediment transport varies considerably in the shore-perpendicular dimension, being substantially higher in the surf-zone than at depth, due to high turbulence and convective flows associated with breaking waves, which suspend and mobilise sediment (Smith & Mocke 2002).

On the inner and middle continental shelf, the ambient currents are insufficient to transport coarse sediments typical of those depths, and re-suspension and shoreward movement of these by wave-induced currents occur primarily under storm conditions (see also Drake *et al.* 1985; Ward 1985). Data from a Waverider buoy at Port Nolloth have indicated that 2-m waves are capable of re-suspending medium sands (200 µm diameter) at -10 m depth, whilst 6-m waves achieve this at -42 m depth. Low-amplitude, long-period waves will, however, penetrate even deeper. Most of the sediment shallower than 90 m can therefore be subject to re-suspension and transport by heavy swells (Lane & Carter 1999).

Offshore of the continental shelf, the oceanic waters are typically clear as they are beyond the influence of aeolian and riverine inputs. The waters in the Reconnaissance Permit Area are thus expected to be comparatively clear.

3.3 The Biological Environment

Biogeographically, the study area falls into the cold temperate Namaqua Bioregion, which extends from Sylvia Hill, north of Lüderitz in Namibia to Cape Columbine (Emanuel *et al.* 1992; Lombard *et al.* 2004). The Reconnaissance Permit Area falls into the Southeast Atlantic Deep Ocean Ecoregion (Sink *et al.* 2019) (Figure 9). The coastal, wind-induced upwelling characterising the western Cape coastline, is the principle physical process which shapes the marine ecology of the southern Benguela region. The Benguela system is characterised by the presence of cold surface water, high biological productivity, and highly variable physical, chemical and biological conditions.

The Southeast Atlantic Oceanic Ecoregion extends from the shelf edge of the Southern Benguela onto the slope and into the abyssal plain of the Cape Basin, which comprises a relatively monotonous plain, interrupted by sporadic seamounts. This deep ocean region extends into Namibia and is bounded in the north by the prominent Walvis Ridge. In the south it is separated from the Southwest Indian Deep

Ocean by the Agulhas Ridge, a transverse ridge that forms part of the Agulhas Falklands Fracture Zone and acts as a divide between the Cape Basin and the Agulhas Basin. The biodiversity patterns in the deep ocean ecosystems are not well understood (Sink *et al.* 2019).

Communities within marine habitats are largely ubiquitous throughout the southern African West Coast region, being particular only to substrate type or depth zone. These biological communities consist of many hundreds of species, often displaying considerable temporal and spatial variability (even at small scales). The offshore marine ecosystems comprise a limited range of habitats, namely unconsolidated seabed sediments, deepwater reefs and the water column. The biological communities 'typical' of these habitats are described briefly below, focussing both on dominant, commercially important and conspicuous species, as well as potentially threatened or sensitive species, which may be affected by the proposed exploration activities.

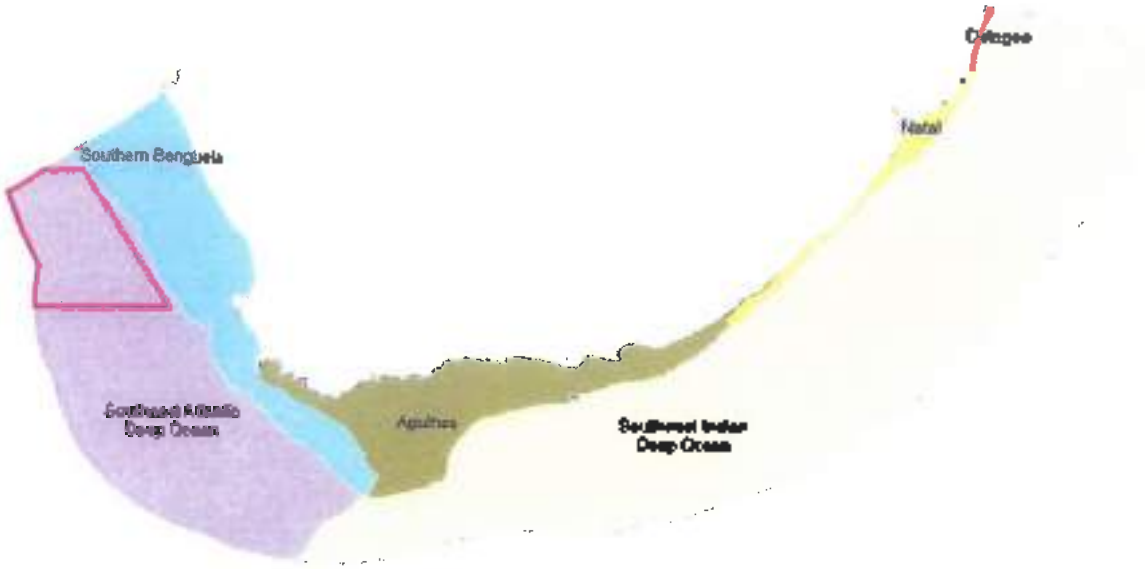

Figure 9: The Reconnaissance Permit Area (red polygon) in relation to the inshore and offshore ecoregions of the South African coast (adapted from Sink *et al.* 2019).

3.3.1 Demersal Communities

3.3.1.1 Benthic Invertebrate Macrofauna

The seabed communities in the Reconnaissance Permit Area lie within the Namaqua sub-photic and continental slope biozones, which extend from a 30 m depth to the shelf edge, and beyond to the lower deepsea slope, respectively. The benthic habitats of South Africa were mapped as part of the 2018 National Biodiversity Assessment (Sink *et al.* 2019) to develop assessments of the ecosystem threat status and ecosystem protection level. The benthic ecosystem types were subsequently mapped (Figure 10) and assigned an ecosystem threat status based on their level of protection (Figure 11). The Reconnaissance Permit Area is characterised by a limited variety of ecosystem types covering the mid- and lower shelves, the Southeast Atlantic continental slope and the Cape Basin Abyss.

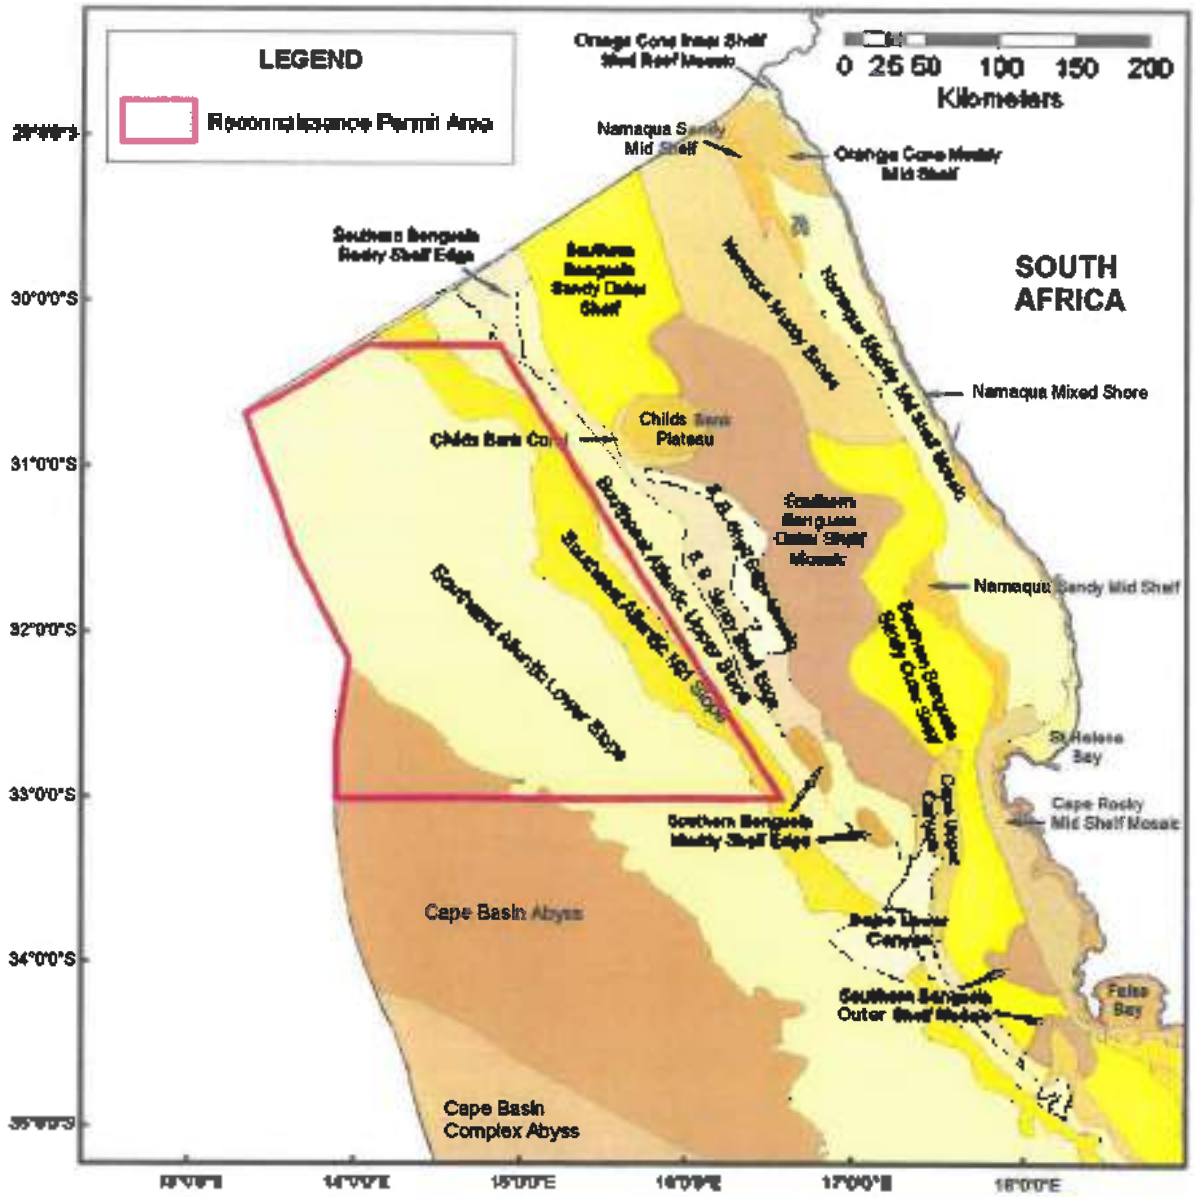

Figure 10: The Reconnaissance Permit Area (red polygon) in relation to the distribution of ecosystem types along the West Coast (adapted from Sink *et al.* 2019). Only those ecosystem types within the immediate vicinity of the Reconnaissance Permit Area are labelled.

The benthic biota of unconsolidated marine sediments constitute invertebrates that live on (epifauna) or burrow within (infauna) the sediments, and are generally divided into macrofauna (animals >1 mm) and meiofauna (<1 mm). Numerous studies have been conducted on southern African West Coast continental shelf benthos, mostly focused on mining, pollution or demersal trawling impacts (Christie & Moldan 1977; Moldan 1978; Jackson & McGibbon 1991; Field *et al.* 1996; Field & Parkins 1997; Parkins & Field 1998; Pulfrich & Penney 1999; Goosen *et al.* 2000; Savage *et al.* 2001; Steffani & Pulfrich 2004; 2007; Steffani 2007a; 2007b; Atkinson 2009; Steffani 2009a, 2009b, 2010a, 2010b, 2010c; Atkinson *et al.* 2011; Steffani 2012a, 2012b, 2014; Karenyi 2014; Steffani *et al.* 2015; Biccard & Clark 2016; Biccard *et al.* 2016; Duna *et al.* 2016; Karenyi *et al.* 2016; Biccard *et al.* 2017, 2018; Giwhala *et al.* 2018; Biccard *et al.* 2019; Giwhala *et al.* 2019). These studies, however, concentrated

on the continental shelf and nearshore regions, and consequently the benthic fauna of the outer shelf and continental slope (beyond ~450 m depth) are very poorly known. This is primarily due to limited opportunities for sampling as well as the lack of access to Remote Operated Vehicles (ROVs) for visual sampling of hard substrata.

To date very few areas on the continental slope off the West Coast have been biologically surveyed (Sink *et al.* 2019; Harris *et al.* 2022). Although sediment distribution studies (Rogers & Bremner 1991) suggest that the outer shelf is characterised by unconsolidated sediments (see Figure 4), recent surveys conducted between 180 m and 480 m depth offshore of the Northern Cape coast revealed high proportions of hard ground rather than unconsolidated sediment, although this requires further verification (Karenyi unpublished data).

To date there have been no studies examining connectivity between slope, plateau or abyssal ecosystems in South Africa and there is thus limited knowledge on the benthic biodiversity of all three of these broad ecosystem groups in South African waters (Sink *et al.* 2019). There is no quantitative data describing bathyal ecosystems in South Africa and hence limited understanding of ecosystem functioning and sensitivity (Anderson & Hulley 2000; Harris *et al.* 2022). Due to the lack of information on benthic macrofaunal communities beyond the shelf break, no description can be provided for the offshore portions of the Reconnaissance Permit Area. However, as these communities would receive the sound in the far field only, no detrimental effects to the communities or to individual benthic species are expected. The description below for areas on the continental shelf, offshore of the Northern Cape coast is drawn from recent surveys by Karenyi (2014), Duna *et al.* (2016), Mostert *et al.* (2016), and Gwhala *et al.* (2018, 2019).

Three macro-infauna communities have been identified on the inner- (0-30 m depth) and mid-shelf (30-150 m depth, Karenyi *et al.* 2016). Polychaetes, crustaceans and molluscs make up the largest proportion of individuals, biomass and species on the west coast. The inner-shelf community, which is affected by wave action, is characterised by various mobile gastropod and polychaete predators and sedentary polychaetes and isopods. The mid-shelf community inhabits the mudbelt and is characterised by mud prawns. A second mid-shelf community occurring in sandy sediments, is characterised by various deposit-feeding polychaetes. The distribution of species within these communities are inherently patchy reflecting the high natural spatial and temporal variability associated with macro-infauna of unconsolidated sediments (e.g. Kenny *et al.* 1998; Kendall & Widdicombe 1999; van Dalfsen *et al.* 2000; Zajac *et al.* 2000; Parry *et al.* 2003), with evidence of mass mortalities and substantial recruitments recorded on the South African West Coast (Steffani & Pulfrich 2004).

Despite the current lack of knowledge of the community structure and endemicity of South African macro-infauna off the edge of the continental shelf, the marine component of the 2018 National Biodiversity Assessment (Sink *et al.* 2019), rated the South Atlantic bathyal and abyssal unconsolidated habitat types that characterise depths beyond 500 m, as being of 'Least concern' (Figure 11), with only those communities occurring along the shelf edge (~500 m) being considered 'Vulnerable'. This primarily reflects the great extent of these habitats in the South African Exclusive Economic Zone (EEZ).

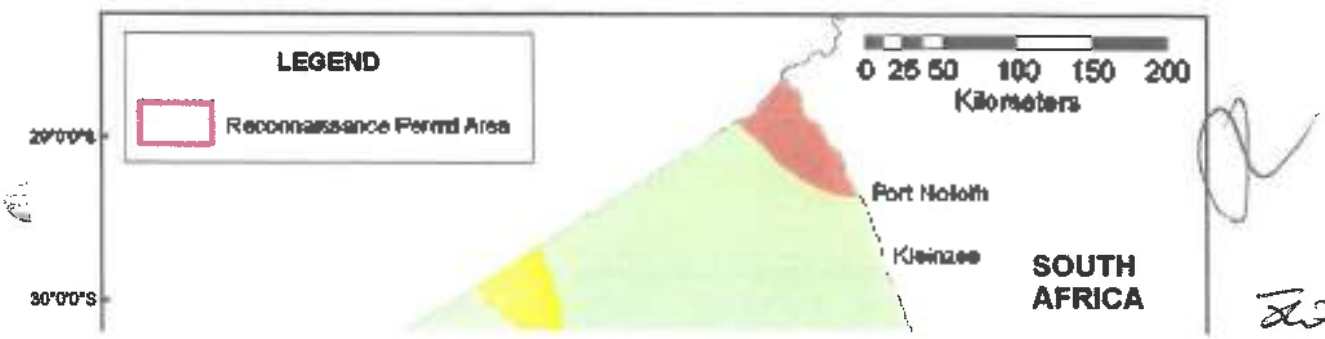

Figure 11: The Reconnaissance Permit Area (red polygon) in relation to the ecosystem threat status for coastal and offshore benthic and pelagic habitat types on the South African West Coast (adapted from Sink *et al.* 2019).

Karenyi *et al.* (2016) found that off Namaqualand, species richness generally increased from the inner-shelf across the mid-shelf and is influenced by sediment type. The highest total abundance and species diversity was measured in sandy sediments of the mid-shelf. Biomass is highest in the inshore (± 50 g/m^2 wet weight) and decreases across the mid-shelf averaging around 30 g/m^2 wet weight. This is contrary to Christie (1974) who found that biomass was greatest in the mudbelt at 80 m depth off Lamberts Bay, where the sediment characteristics and the impact of environmental stressors (such as low oxygen events) are likely to differ from those off the northern Namaqualand coast.

Benthic communities are structured by the complex interplay of a large array of environmental factors. Water depth and sediment grain size are considered the two major factors that determine benthic community structure and distribution on the South African west coast (Christie 1974, 1976; Steffani & Pulfrich 2004a, 2004b; 2007; Steffani 2007a; 2007b) and elsewhere in the world (e.g. Gray 1981; Ellingsen 2002; Bergen *et al.* 2001; Post *et al.* 2006). However, studies have shown that shear

bed stress - a measure of the impact of current velocity on sediment - oxygen concentration (Post *et al.* 2006; Currie *et al.* 2009; Zettler *et al.* 2009, 2013), productivity (Escaravage *et al.* 2009), organic carbon and seafloor temperature (Day *et al.* 1971) may also strongly influence the structure of benthic communities. There are clearly other natural processes operating in the deep water shelf areas of the West Coast that can over-ride the suitability of sediments in determining benthic community structure, and it is likely that periodic intrusion of low oxygen water masses is a major cause of this variability (Monteiro & van der Plas 2006; Pulfrich *et al.* 2006). In areas of frequent oxygen deficiency, benthic communities will be characterised either by species able to survive chronic low oxygen conditions, or colonising and fast-growing species able to rapidly recruit into areas that have suffered oxygen depletion. The combination of local, episodic hydrodynamic conditions and patchy settlement of larvae will tend to generate the observed small-scale variability in benthic community structure.

The invertebrate macrofauna are important in the marine benthic environment as they influence major ecological processes (e.g. remineralisation and flux of organic matter deposited on the sea floor, pollutant metabolism, sediment stability) and serve as important food source for commercially valuable fish species and other higher order consumers. As a result of their comparatively limited mobility and permanence over seasons, these animals provide an indication of historical environmental conditions and provide useful indices with which to measure environmental impacts (Gray 1974; Warwick 1993; Salas *et al.* 2006).

Also associated with soft-bottom substrates are demersal communities that comprise epifauna and bottom-dwelling vertebrate species, many of which are dependent on the invertebrate benthic macrofauna as a food source. According to Lange (2012) the continental shelf on the West Coast between depths of 100 m and 250 m, contained a single epifaunal community characterised by the hermit crabs *Sympagurus dimorphus* and *Parapagurus pilosimanus*, the prawn *Funchalia woodwardi* and the sea urchin *Brissaster capensis*. Atkinson (2009) also reported numerous species of urchins and burrowing anemones beyond 300 m depth off the West Coast.

Information on the benthic fauna of the lower continental slope and abyss (beyond 1 800 m depth) is largely lacking due to limited opportunities for sampling. However, deep water benthic sampling was undertaken (Benthic Solutions Ltd 2019) as part of the Environmental Baseline Survey for Total E&P Namibia's Block 2913B just to the north of the Reconnaissance Permit Area. This provided valuable information on the benthic infaunal communities of the lower continental slope. As conditions in such deep water habitats tend to be more uniform (low temperatures and low oxygen concentrations characterising the SACW that comprises the bulk of the water in the area), similar communities may be expected in the Reconnaissance Permit Area.

The macrofauna in Block 2913B were generally impoverished but fairly consistent, which is typical for deep water sediments. The 105 species recorded, were dominated by polychaetes, which accounted for 64.1% of the total individuals. Molluscs were represented by 11 species (19.6% of total individuals), whilst 20 species of crustaceans were recorded (contributing to only 9.8% of total individuals). Echinoderms were represented by only 3 species (5.8% of total individuals), whilst all other groups (Actiniaria, Nemertea, Nematoda, Ascidiacea and Priapulida) accounted for the remaining 5.9% of individuals. The deposit-feeding polychaete *Spiophanes* sp. was the most abundant species recorded. This small bristleworm can either be a passive suspension feeder or a surface deposit feeder, living off sediment particles, planktonic organisms and meiobenthic organisms. The bivalve mollusc *Microgloma mirabilina* was the second most common species, with the polychaete tentatively identified as a *Leiocapitellide* being the third most abundant. With the exception of the carnivorous

polychaete *Glycera capitata*, most species were suspension or deposit feeders typical of soft unconsolidated sediments.

Examples of the macroinvertebrate infauna of the Block 2913B area are illustrated in Figure 12. A wide diversity of macroinvertebrates has been recorded inshore of the 1 000 m depth contour, and the reader is referred to the comprehensive field guide compiled by Atkinson & Sink (2018).

The 2018 National Biodiversity Assessment for the marine environment (Sink *et al.* 2019) points out that very few national IUCN Red List assessments have been conducted for marine invertebrate species to date owing to inadequate taxonomic knowledge, limited distribution data, a lack of systematic surveys and limited capacity to advance species red listing for these groups.

3.3.1.2 Deep-water coral communities

There has been increasing interest in deep-water corals in recent years because of their likely sensitivity to disturbance and their long generation times. These benthic filter-feeders generally occur at depths in below 150 m with some species being recorded from as deep as 3 000 m. Some species form reefs while others are smaller and remain solitary. Corals add structural complexity to otherwise uniform seabed habitats thereby creating areas of high biological diversity (Breeze *et al.* 1997; Macissac *et al.* 2001). Deep water corals establish themselves below the thermocline where there is a continuous and regular supply of concentrated particulate organic matter, caused by the flow of a relatively strong current over special topographical formations which cause eddies to form. Nutrient seepage from the substratum might also promote a location for settlement (Rowland *et al.* 2002). In the productive Benguela region, substantial areas on and off the edge of the shelf should thus potentially be capable of supporting rich, cold water, benthic, filter-feeding communities, and various species of scleractine and stylastrine corals have been reported from depths beyond -200 m in the Orange Basin.

Such communities would also be expected with topographic features such as seamounts located adjacent to the northern and western boundary of the Reconnaissance Permit Area (see Figure 2). Nonetheless, our understanding of the invertebrate fauna of the sub-photic zone is relatively poor (Gibbons *et al.* 1999) and the conservation status of the majority of invertebrates in this bioregion is not known.

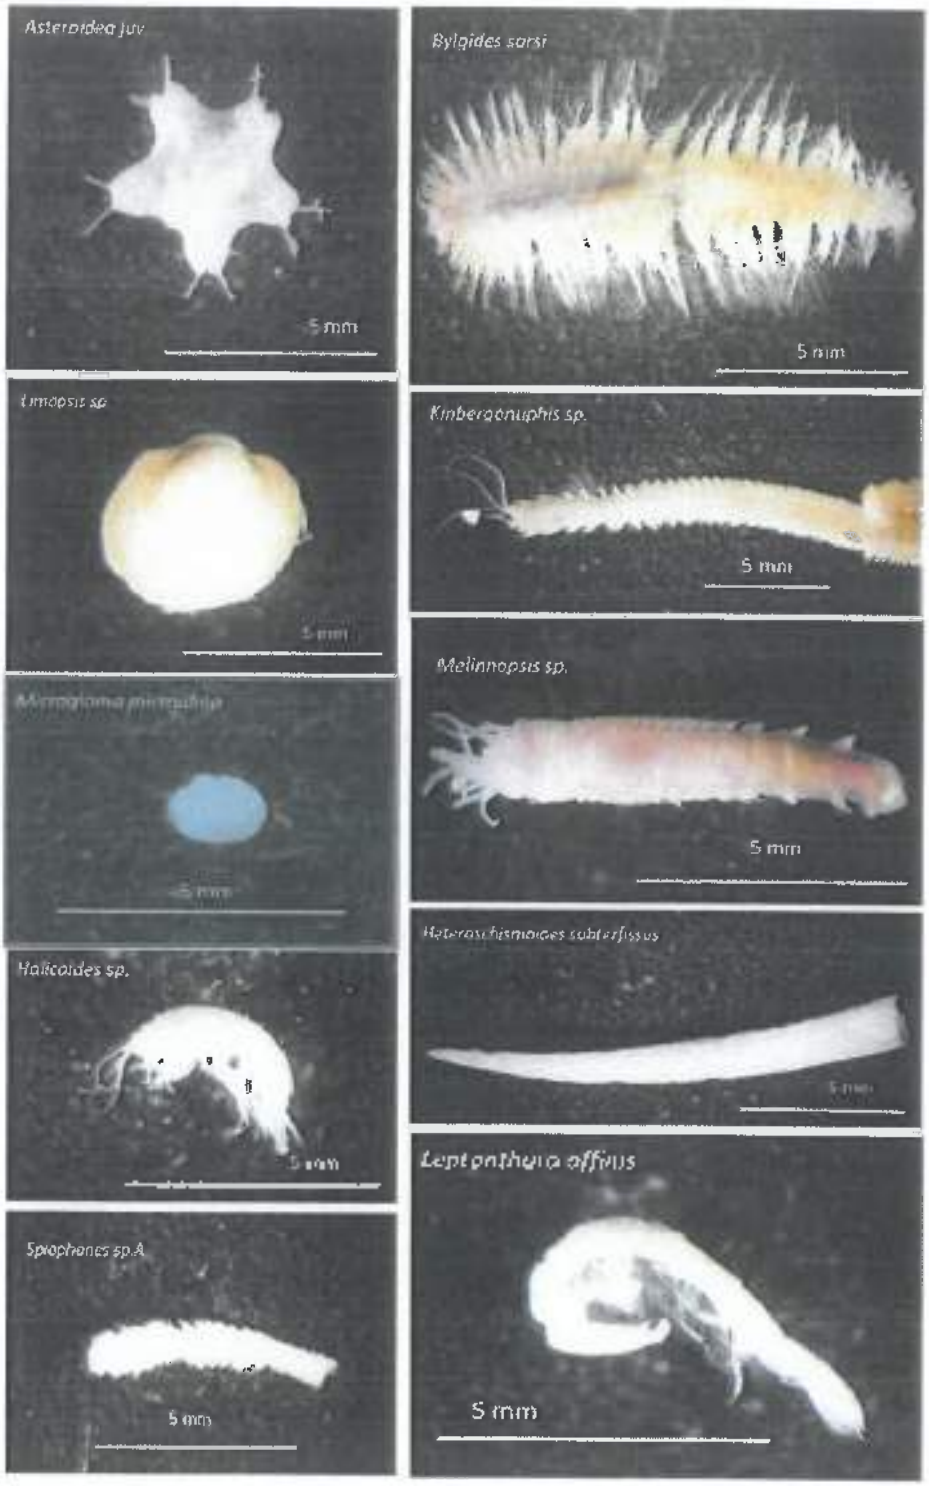

Figure 12: Examples of macroinvertebrates recorded in Block 2913B to the north of the Reconnaissance Permit Area (Source Benthic Solutions Ltd 2019).

3.3.1.3 Demersal Fish Species

Demersal fish are those species that live and feed on or near the seabed. As many as 110 species of bony and cartilaginous fish have been identified in the demersal communities on the continental shelf of the West Coast (Roel 1987). Details on demersal fish communities beyond the shelf break and in the Reconnaissance Permit Area are, however, lacking (see Harris *et al.* 2022). Changes in fish communities occur both latitudinally (Shine 2006, 2008; Yemane *et al.* 2015) and with increasing depth (Roel 1987; Smale *et al.* 1993; Macpherson & Gordoa 1992; Bianchi *et al.* 2001; Atkinson 2009; Yemane *et al.* 2015), with the most substantial change in species composition occurring in the shelf break region between 300 m and 400 m depth (Roel 1987; Atkinson 2009). The shelf community (<380 m) is dominated by the Cape hake *M. capensis*, and includes jacopever *Helicolenus dactylopterus*, Izak catshark *Holohalaelurus regani*, soupfin shark *Galeorhinus galeus* and whitespotted houndshark *Mustelus palumbes*. The more diverse deeper water community is dominated by the deepwater hake *Merluccius paradoxus*, monkfish *Lophius vomerinus*, kingklip *Genypterus capensis*, bronze whiptail *Lucigadus ori* and hairy conger *Bassanago albescens* and various squalid shark species. There is some degree of species overlap between the depth zones.

Roel (1987) showed seasonal variations in the distribution ranges shelf communities, with species such as the pelagic goby *Sufflogobius bibarbatus*, and West Coast sole *Austroglossus microlepis* occurring in shallow water north of Cape Point during summer only. The deep-sea community was found to be homogenous both spatially and temporally. In a more recent study, however, Atkinson (2009) identified two long-term community shifts in demersal fish communities: the first (early to mid-1990s) being associated with an overall increase in density of many species, whilst many species decreased in density during the second shift (mid-2000s). These community shifts correspond temporally with regime shifts detected in environmental forcing variables (Sea Surface Temperatures and upwelling anomalies) (Howard *et al.* 2007) and with the eastward shifts observed in small pelagic fish species and rock lobster populations (Coetzee *et al.* 2008, Cockcroft *et al.* 2008).

The diversity and distribution of demersal cartilagenous fishes on the West Coast is discussed by Compagno et al. (1991). The species that may occur in the general project area and on the continental shelf inshore thereof, and their approximate depth range, are listed in Table 1. Details on demersal cartilaginous species beyond the shelf break and in the Reconnaissance Permit Area are lacking, however.

There is limited information about bathyal fish communities in South Africa. South Africa defines its bathyal zone as extending from 500 m to 3 500 m, recognising an upper slope (500-1 000 m), mid slope (1 000-1 800 m) and lower slope (1 800-3 500 m). Typical upper slope fishes (200-2 000 m) include rattails (Macrouridae), greeneyes (*Chlorophthalmus* species), notacanthids, halosaurs, chimaeras, skates, bythitids such as *Cataetyx* spp. and moridS (deepsea cods) (Smith & Heemstra 2003). Rattails, bythitids, liparidids (snail fishes) and notacanthids (*Polyacanthonotus* species and halosaurs) are characteristic of the lower bathyal (see also Iwamoto & Anderson 1994; Jones 2014).

Table 1: Demersal cartilaginous species found on the continental shelf along the West Coast, with approximate depth range at which the species occurs (Compagno *et al.* 1991) and their IUCN conservation status. The National Assessment is provided in parentheses where available.

Common Name	Scientific name	Depth Range (m)	IUCN Conservation Status
Frilled shark	*Chlamydoselachus anguineus*	200-1 000	LC

3.3.2 Seamount and Submarine Canyon Communities

Features such as banks, knolls and seamounts (referred to collectively here as "seamounts"), which protrude into the water column, are subject to, and interact with, the water currents surrounding them. The effects of such seabed features on the surrounding water masses can include the up-welling of relatively cool, nutrient-rich water into nutrient-poor surface water thereby resulting in higher productivity (Clark *et al.* 1999), which can in turn strongly influences the distribution of organisms on and around seamounts. Evidence of enrichment of bottom-associated communities and high abundances of demersal fishes has been regularly reported over such seabed features.

The enhanced fluxes of detritus and plankton that develop in response to the complex current regimes lead to the development of detritivore-based food-webs, which in turn lead to the presence of seamount scavengers and predators. Seamounts provide an important habitat for commercial deepwater fish stocks such as orange roughy, oreos, alfonsino and Patagonian toothfish, which aggregate around these features for either spawning or feeding (Koslow 1996).

Such complex benthic ecosystems in turn enhance foraging opportunities for many other predators, serving as mid-ocean focal points for a variety of pelagic species with large ranges (turtles, tunas and billfish, pelagic sharks, cetaceans and pelagic seabirds) that may migrate large distances in search of food or may only congregate on seamounts at certain times (Hui 1985; Haney *et al.* 1995). Seamounts thus serve as feeding grounds, spawning and nursery grounds and possibly navigational markers for a large number of species (SPRFMA 2007; Derville *et al.* 2020).

Enhanced currents, steep slopes and volcanic rocky substrata, in combination with locally generated detritus, favour the development of suspension feeders in the benthic communities characterising seamounts (Rogers 1994). Deep- and cold-water corals (including stony corals, black corals and soft corals) are a prominent component of the suspension-feeding fauna of many seamounts, accompanied

by barnacles, bryozoans, polychaetes, molluscs, sponges, sea squirts, basket stars, brittle stars and crinoids (reviewed in Rogers 2004). There is also associated mobile benthic fauna that includes echinoderms (sea urchins and sea cucumbers) and crustaceans (crabs and lobsters) (reviewed by Rogers 1994; Kenyon *et al.* 2003). Some of the smaller cnidarians species remain solitary while others form reefs thereby adding structural complexity to otherwise uniform seabed habitats.

Consequently, the fauna of seamounts is usually highly unique and may have a limited distribution restricted to a single geographic region, a seamount chain or even a single seamount location (Rogers *et al.* 2008). As a result of conservative life histories (*i.e.* very slow growing, slow to mature, high longevity, low fecundity and unpredictable recruitment) and sensitivity to changes in environmental conditions, such biological communities have been identified as Vulnerable Marine Ecosystems (VMEs). They are recognised as being particularly sensitive to anthropogenic disturbance (primarily deep-water trawl fisheries and mining), and once damaged are very slow to recover, or may never recover (FAO 2008).

Geological features of note within the broader project area are Child's Bank and Tripp Seamount, with an unnamed seamount located in ~3 500 m at ~32°20'S; 13°30'E, as well as the Cape Canyon and Cape Point Valley. Child's Bank, which is situated at about 31°S, was described by Dingle *et al.* (1987) to be a carbonate mound (bioherm). The top of this feature is a sandy plateau with dense aggregations of brittle stars, while the steeper slopes have dense invertebrate assemblages including unidentified cold-water corals/rugged limestone feature, bounded at outer edges by precipitous cliffs at least 150 m high (Birch & Rogers 1973). Composed of sediments and the calcareous deposits from an accumulation of carbonate skeletons of sessile organisms (e.g. cold-water coral, foraminifera or marl), such features typically have topographic relief, forming isolated seabed knolls in otherwise low profile homogenous seabed habitats (Kopaska-Merkel & Haywick 2001; Kenyon *et al.* 2003, Wheeler *et al.* 2005, Colman *et al.* 2005). Tripp Seamount situated at about 29°40'S, lies ~30 km north of the northern boundary of the survey area. It rises from the seabed at ~1 000 m to a depth of 150 m and roughly circular with a flat apex that drops steeply on all sides. There is reference to decapods crustaceans from Tripp Seamount (Kensley 1980, 1981) and exploratory deepwater trawl fishing (Hampton 2003), but otherwise knowledge of benthic communities characterising this seamount is lacking.

The Cape Rise comprises a group of NE-SW trending seamounts - the Southeast Atlantic Seamounts - which include Argentina and Protea Seamounts and the recently discovered Mount Marek. These rise up from over ~2 500 m depth in the Cape Basin abyss to 700 m deep. Other than a geoscience survey conducted in 1986 using a deep water camera to sample the lower bathyal and abyssal zones, including the seamount flanks, of the Cape Basin (Rogers 1986) no biodiversity surveys are known to have been conducted at Protea and Argentina seamounts. Southern Africa's seamounts and their associated benthic communities have not been sampled by either geologists or biologists (Sink & Samaai 2009) and little is known about the benthic and neritic communities associated with them.

A recent study reporting on the megabenthos and benthopelagic fish on the Southeast Atlantic Seamounts (Bergstad *et al.* 2019), provides descriptions of the Erica and Schmitt-Ott Seamounts that lie approximately 450 - 500 km southwest of the Argentina Seamount and rise from the surrounding abyss to depths of 770 m and 920 m, respectively. Corals were the most frequent and widespread sessile invertebrate recorded on video transects, dominated by gorgonians whose abundance increased towards the seamount summits. Scleractinian and hydrocorals were also observed as was a diversity of sponges, echinoderms and crustaceans. Fish associated with the seamount included

oreo dories, grenadiers and lanternshark. Similar communities might therefore be expected from the Protea and Argentina Seamounts.

During 2016-2018 the Department of Environmental Affairs: Oceans and Coast Branch (DEA: O&C) undertook research cruises to explore some of the undocumented areas of seabed off the West Coast, among them the Cape Canyon. Using tow-cameras, benthic grabs and dredges, the biota of the canyon head to ~500 m depth were sampled (Figure 13). A diversity of echinoderms, molluscs, and crustaceans were reported to dominate the canyon head, while scavengers such as ophiuroidea and decapoda were prevalent within habitats ranging from sandy areas, to patches of inshore and offshore mud belts. At depths of <100 m inshore of the canyon head, boulder beds hosted gorgonian and stylasterine corals.

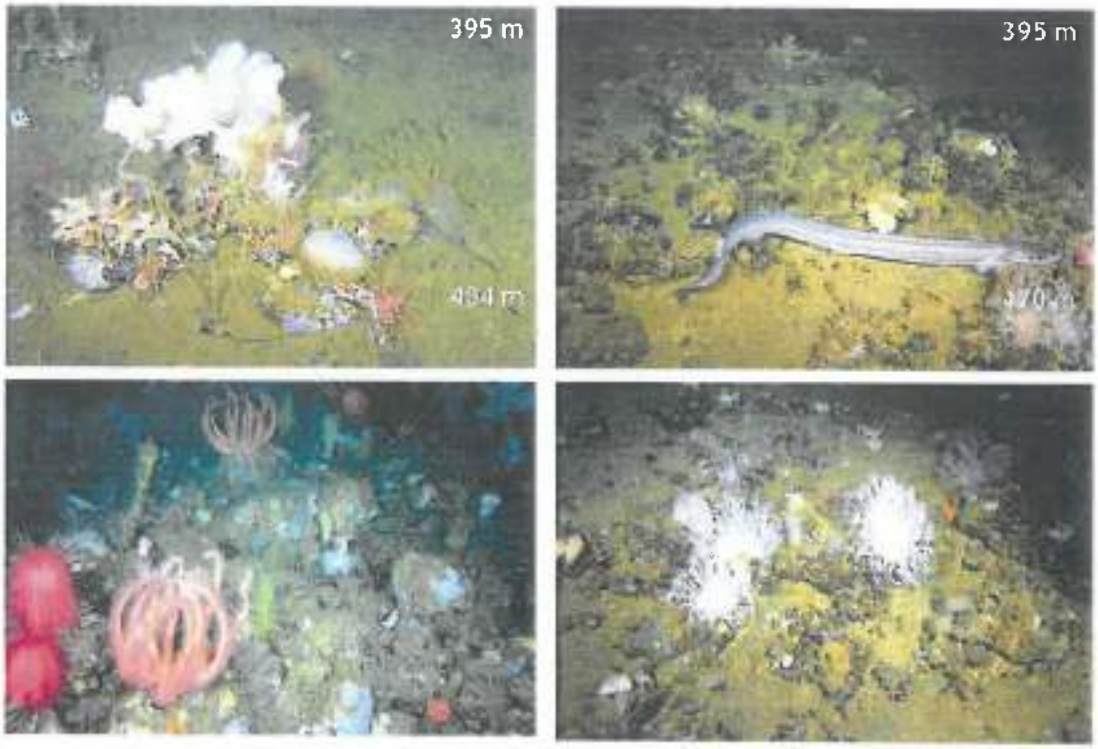

Figure 13: Deep water benthic macrofauna from various depths in the Cape Canyon (Source: www.environment.gov.za/dearesearchteamreturnfromdeepseaexpedition).

The concept of a 'Vulnerable Marine Ecosystem' (VME) centres upon the presence of distinct, diverse benthic assemblages that are limited and fragmented in their spatial extent, and dominated (in terms of biomass and/or spatial cover) by rare, endangered or endemic component species that are physically fragile and vulnerable to damage (or structural/biological alteration) by human activities (Parker *et al.* 2009; Auster *et al.* 2011; Hansen *et al.* 2013).

VMEs are known to be associated with higher biodiversity levels and indicator species that add structural complexity, resulting in greater species abundance, richness, biomass and diversity compared to surrounding uniform seabed habitats (Buhl-Mortensen *et al.* 2010; Hogg *et al.* 2010; Barrio Froján *et al.* 2012; Beazley *et al.* 2013, 2015). Compared to the surrounding deep-sea environment, VMEs typically form biological hotspots with a distinct, abundant and diverse fauna,

908

many species of which remain unidentified. Levels of endemism on VMEs are also relatively high compared to the deep sea. The coral frameworks offer refugia for a great variety of invertebrates and fish (including commercially important species) within, or in association with, the living and dead coral framework thereby creating spatially fragmented areas of high biological diversity. The skeletal remains of Scleractinia coral rubble and Hexactinellid poriferans can also represent another important deep-sea habitat, acting to stabilise seafloor sediments allowing for colonisation by distinct infaunal taxa that show elevated abundance and biomass in such localised habitats (Bett & Rice 1992; Raes & Vanreusel 2005; Beazley *et al.* 2013; Ashford *et al.* 2019).

VMEs are also thought to contribute toward the long-term viability of a stock through providing an important source of habitat for commercial species (Pham *et al.* 2015; Ashford *et al.* 2019). They can provide a wide range of ecosystem services ranging from provision of aggregation- and spawning sites to providing shelter from predation and adverse hydrological conditions (Husebø & Nøttestad *et al.* 2002; Krieger & Wing, 2002; Tissot *et al.*, 2006; Baillon *et al.* 2012; Pham *et al.* 2015). Indicator taxa for VMEs are also known to provide increased access to food sources, both directly to associated benthic fauna, and indirectly to other pelagic species such as fish and other predators due to the high abundance and biomass of associated fauna (Krieger & Wing, 2002; Husebø & Nøttestad *et al.* 2002; Buhl-Mortensen *et al.*, 2010; Hogg *et al.*, 2010; Auster *et al.* 2011).

VME frameworks are typically elevated from the seabed, increasing turbulence and raising supply of suspended particles to suspension feeders (Krieger & Wing 2002; Buhl-Mortensen & Mortensen 2005; Buhl-Mortensen *et al.* 2010). Poriferans and cold-water corals have further been shown to provide a strong link between pelagic and benthic food webs (Pile & Young 2006; Cathalot *et al.* 2015). VMEs are increasingly being recognised as providers of important ecosystem services due to associated increased biodiversity and levels of ecosystem functioning (Ashford *et al.* 2019).

It is not always the case that seamount habitats are VMEs, as some seamounts may not host communities of fragile animals or be associated with high levels of endemism. Evidence from video footage taken on hard-substrate habitats in 100 - 120 m depth off southern Namibia and to the south-east of Child's Bank (De Beers Marine, unpublished data) (Figure 14), and in 190-527 m depth on Child's Bank (Sink *et al.* 2019) suggest that vulnerable communities including gorgonians, octocorals and reef-building sponges and hard-corals do occur on the continental shelf, some of which are thought to be Vulnerable Marine Ecosystem (VME) indicator species (Table 2). The distribution of 22 potential VME indicator taxa for the South African EEZ was recently mapped, with those from the West Coast listed in Table 2 (Atkinson & Sink 2018; Sink *et al.* 2019).

As sampling beyond 1 000 m depth has not taken place (Atkinson & Sink 2018) it is not known whether similar communities may be expected in the Reconnaissance Permit Area. Should they occur, however, they would receive the sound in the far field only and no detrimental effects to the communities or to individual benthic species are expected. The distribution of known and potential Vulnerable Marine Ecosystem habitat based on potential VME features, DFFE and SAEON trawl survey data, and many visual surveys indicating the presence of indicator taxa were mapped by Harris *et al.* 2022 (Figure 15). Some sites need more research to determine their status. The location of the Reconnaissance Permit Area is well offshore of these known and potential VMEs emphasising the gaps in our knowledge specific to the vulnerability of marine communities of abyssal habitats.

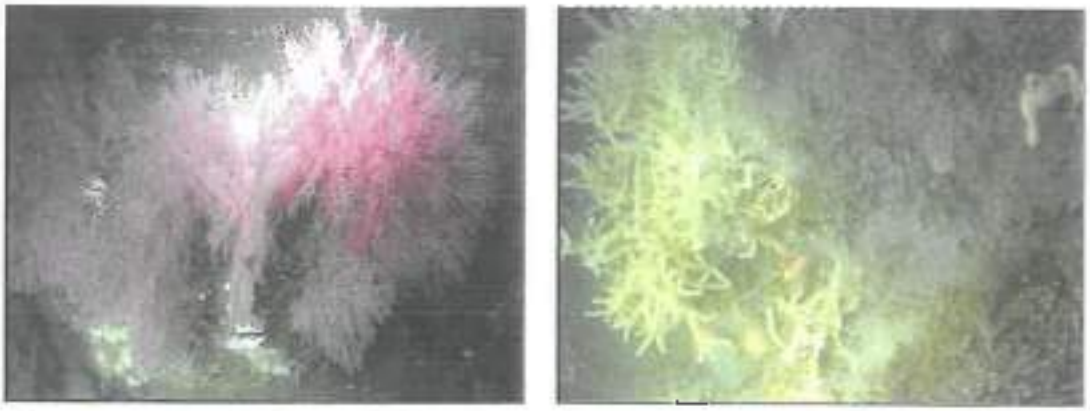

Figure 14: Gorgonians and bryozoans communities recorded on deep-water reefs (100-120 m) off the southern African West Coast (Photos: De Beers Marine).

Table 2: Table of Potential VME species from the the continental shelf and shelf edge on the West Coast (Atkinson & Sink 2018)

Phylum	Name	Common Name
Porifera	*Suberites dendelenae*	Amorphous solid sponge
	Rossella cf. antarctica	Glass sponge
Cnidaria	*Melithaea* spp.	Colourful sea fan
	Thouarella spp.	Bottlebrush sea fan
Family: Isididae	?	Bamboo coral
	Anthoptilum grandiflorum	Large sea pen*
	Lophelia pertusa	Reef-building cold water coral
	Solaster spp.	Fine-branching hydrocoral
Bryozoa	*Adeonella* spp.	Sabre bryozoan
	Phidoloporidae spp.	Honeycomb false lace coral
Hemichordata	*Cephalodiscus gilchristi*	Agar animal

Sediment samples collected at the base of Norwegian cold-water coral reefs revealed high interstitial concentrations of light hydrocarbons (methane, propane, ethane and higher hydrocarbons C4+) (Hovland & Thomsen 1997), which are typically considered indicative of localised light hydrocarbon micro-seepage through the seabed. Bacteria and other micro-organisms thrive on such hydrocarbon pore-water seepages, thereby providing suspension-feeders, including corals and gorgonians, with a substantial nutrient source. Some scientists believe there is a strong correlation between the occurrence of deep-water coral reefs and the relatively high values of light hydrocarbons (methane, ethane, propane and n-butane) in near-surface sediments (Hovland *et al.* 1998, Duncan & Roberts 2001, Hall-Spencer *et al.* 2002, Roberts & Gage 2003). A recent study by January (2018) identified that hydrocarbon seeps and gas escape structures have been identified in the Orange Basin area. Large fluid seep/pockmark fields of varying morphologies were also reported to the south of the Reconnaissance Permit Area by Palan (2017).

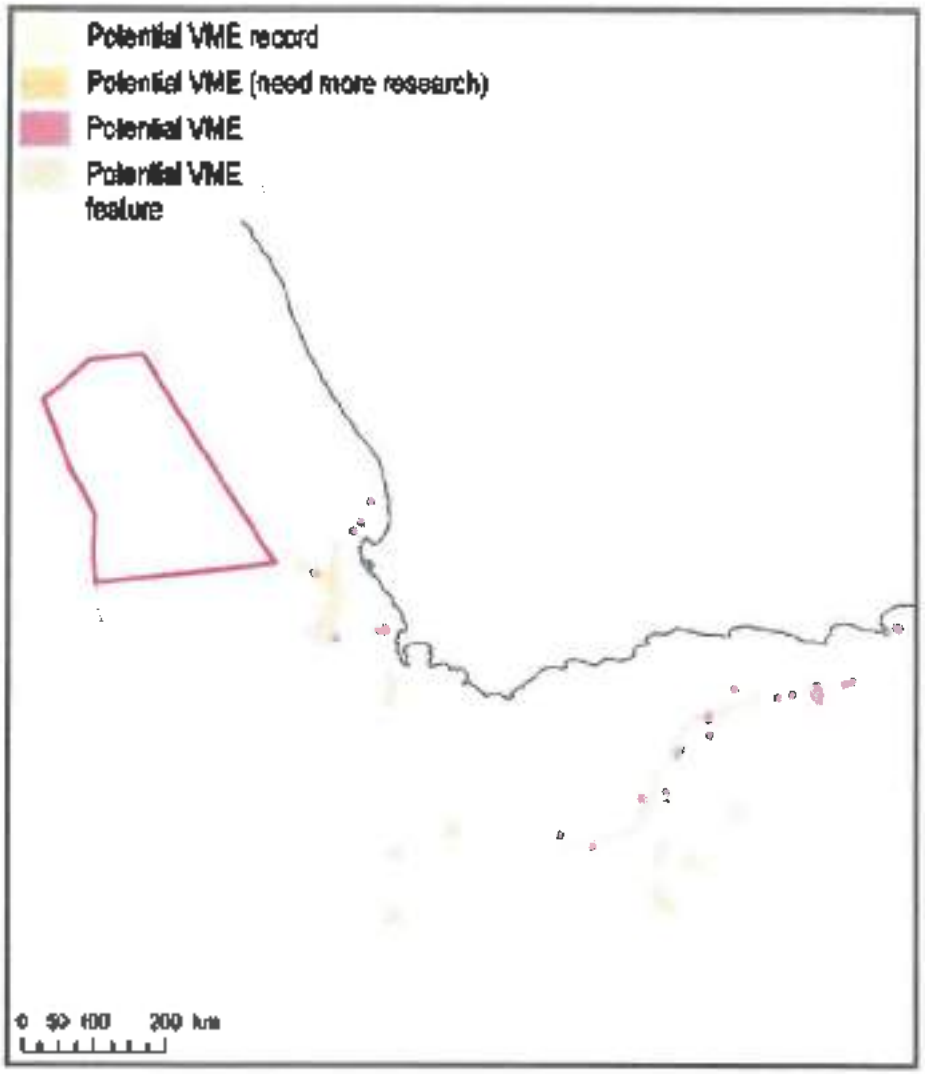

Figure 15: The Reconnaissance Permit Area (red polygon) in relation to the distribution of known and potential Vulnerable Marine Ecosystem habitat (adapted from Harris *et al.* 2022).

3.3.3 Pelagic Communities

In contrast to demersal and benthic biota associated with the seabed, pelagic species live and feed in the open water column. The pelagic communities are typically divided into plankton and fish, and their main predators, marine mammals (seals, dolphins and whales), seabirds and turtles. These are discussed separately below.

3.3.3.1 *Plankton*

Plankton is particularly abundant in the shelf waters off the West Coast, being associated with the upwelling characteristic of the area. Plankton range from single-celled bacteria to jellyfish of 2-m diameter, and include bacterio-plankton, phytoplankton, zooplankton, and ichthyoplankton (Figure 16).

803

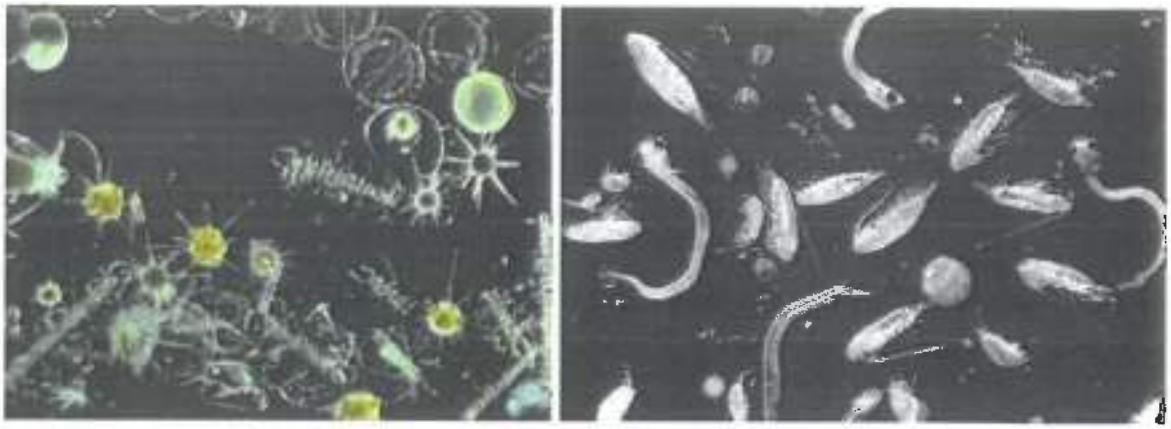

Figure 16: Phytoplankton (left, photo: hymagazine.com) and zooplankton (right, photo: mysciencebox.org) is associated with upwelling cells.

Phytoplankton are the principle primary producers with mean productivity ranging from 2.5 - 3.5 g C/m^2/day for the midshelf region and decreasing to 1 g C/m^2/day inshore of 130 m (Shannon & Field 1985; Mitchell-Innes & Walker 1991; Walker & Peterson 1991). The phytoplankton is dominated by large-celled organisms, which are adapted to the turbulent sea conditions. The most common diatom genera are *Chaetoceros, Nitzchia, Thalassiosira, Skeletonema, Rhizosolenia, Coscinodiscus* and *Asterionella* (Shannon & Pillar 1985). Diatom blooms occur after upwelling events, whereas dinoflagellates (e.g. *Prorocentrum, Ceratium* and *Peridinium*) are more common in blooms that occur during quiescent periods, since they can grow rapidly at low nutrient concentrations. In the surf zone, diatoms and dinoflagellates are nearly equally important members of the phytoplankton, and some silicoflagellates are also present.

Red-tides are ubiquitous features of the Benguela system (see Shannon & Pillar, 1986). The most common species associated with red tides (dinoflagellate and/or ciliate blooms) are *Noctiluca scintillans, Gonyaulax tamarensis, G. polygramma* and the ciliate *Mesodinium rubrum*. *Gonyaulax* and *Mesodinium* have been linked with toxic red tides. Most of these red-tide events occur quite close inshore although Hutchings *et al.* (1983) have recorded red-tides 30 km offshore. They are unlikely to occur in the offshore regions of the proposed 3D survey area.

The mesozooplankton (≥200 µm) is dominated by copepods, which are overall the most dominant and diverse group in southern African zooplankton. Important species are *Centropages brachiatus, Calanoides carinatus, Metridia lucens, Nannocalanus minor, Clausocalanus arcuicornis, Paracalanus parvus, P. crassirostris* and *Ctenocalanus vanus*. All of the above species typically occur in the phytoplankton rich upper mixed layer of the water column, with the exception of *M. lucens* which undertakes considerable vertical migration.

The macrozooplankton (≥1 600 µm) are dominated by euphausiids of which 18 species occur in the area. The dominant species occurring in the nearshore are *Euphausia lucens* and *Nyctiphanes capensis*, although neither species appears to survive well in waters seaward of oceanic fronts over the continental shelf (Pillar *et al.* 1991).

Standing stock estimates of mesozooplankton for the southern Benguela area range from 0.2 - 2.0 g C/m^3, with maximum values recorded during upwelling periods. Macrozooplankton biomass ranges from 0.1-1.0 g C/m^2, with production increasing north of Cape Columbine (Pillar 1986). Although it shows no appreciable onshore-offshore gradients, standing stock is highest over the shelf, with

accumulation of some mobile zooplankters (euphausiids) known to occur at oceanographic fronts. Beyond the continental slope biomass decreases markedly. Localised peaks in biomass may, however, occur in the vicinity of Child's Bank and Tripp Seamount in response to topographically steered upwelling around such seabed features.

Zooplankton biomass varies with phytoplankton abundance and, accordingly, seasonal minima will exist during non-upwelling periods when primary production is lower (Brown 1984; Brown & Henry 1985), and during winter when predation by recruiting anchovy is high. More intense variation will occur in relation to the upwelling cycle; newly upwelled water supporting low zooplankton biomass due to paucity of food, whilst high biomasses develop in aged upwelled water subsequent to significant development of phytoplankton. Irregular pulsing of the upwelling system, combined with seasonal recruitment of pelagic fish species into West Coast shelf waters during winter, thus results in a highly variable and dynamic balance between plankton replenishment and food availability for pelagic fish species.

Although ichthyoplankton (fish eggs and larvae) comprise a minor component of the overall plankton, it remains significant due to the commercial importance of the overall fishery in the region. Various pelagic and demersal fish species are known to spawn in the inshore regions of the southern Benguela, (including pilchard, round herring, chub mackerel lanternfish and hakes (Crawford *et al.* 1987; Hutchings 1994; Hutchings *et al.* 2002) (see Figure 17, Figure 18a and 18b, and Figure 19), and their eggs and larvae form an important contribution to the ichthyoplankton in the region. Spawning of key species is presented below.

- Hake, snoek and round herring move to the western Agulhas Bank and southern west coast to spawn in late winter and early spring (key period), when offshore Ekman losses are at a minimum and their eggs and larvae drift northwards and inshore to the west coast nursery grounds. Figure 18a and 18b highlight the temporal variation in hake eggs and larvae with there being a greater concentration of eggs and larvae between September - October compared to March - April. However, hake are reported to spawn throughout the year (Stremme *et al.* 2015). Snoek spawn along the shelf break (150-400 m) of the western Agulhas Bank and the West Coast between June and October (Griffiths 2002).
- Horse mackerel spawn over the east/central Agulhas Bank during winter months.
- Sardines spawn on the whole Agulhas Bank during November, but generally have two spawning peaks, in early spring and autumn, on either side of the peak anchovy spawning period (Figure 19, left). There is also sardine spawning on the east coast and even off KwaZulu-Natal, where sardine eggs are found during July-November.
- Anchovies spawn on the whole Agulhas Bank (Figure 19, right), with spawning peaking during mid-summer (November-December) and some shifts to the west coast in years when Agulhas Bank water intrudes strongly north of Cape Point.

The eggs and larvae are carried around Cape Point and up the coast in northward flowing surface waters. At the start of winter every year, the juveniles recruit in large numbers into coastal waters across broad stretches of the shelf between the Orange River and Cape Columbine to utilise the shallow shelf region as nursery grounds before gradually moving southwards in the inshore southerly flowing surface current, towards the major spawning grounds east of Cape Point. Following spawning, the eggs and larvae of snoek are transported to inshore (<150 m) nursery grounds north of Cape Columbine and east of Danger Point, where the juveniles remain until

maturity. There is no overlap of the Reconnaissance Permit Area or indicative 3D acquisition area with the northward egg and larval drift of commercially important species, and the return migration of recruits (Figure 17). In the offshore oceanic waters of the proposed 3D survey area, ichthyoplankton abundance is, therefore, expected to be low.

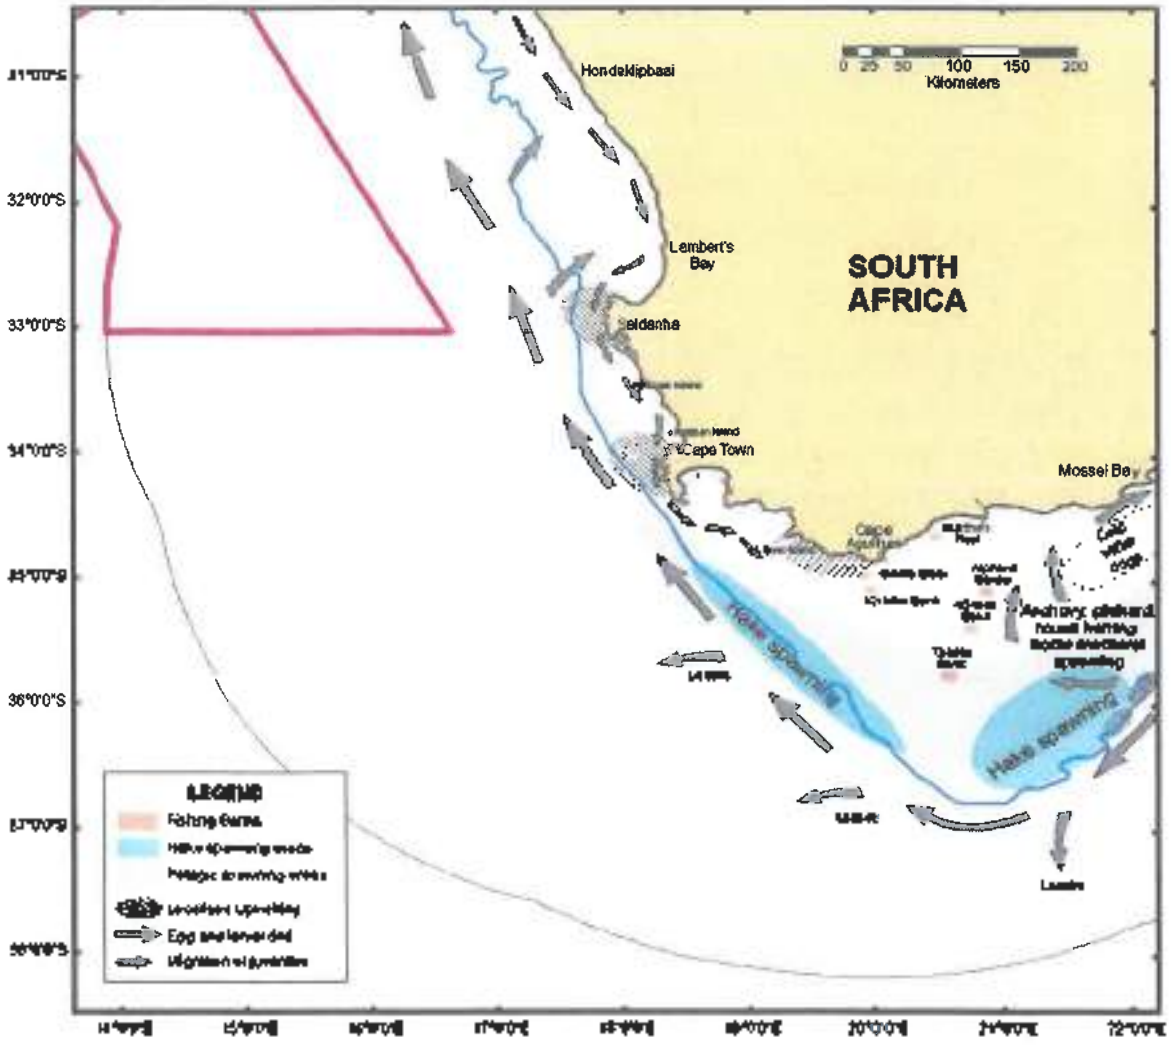

Figure 17: The Reconnaissance Permit Area (red polygon) in relation to major spawning, recruitment and nursery areas in the southern Benguela region (adapted from Crawford *et al.* 1987; Hutchings 1994; Hutchings *et al.* 2002).

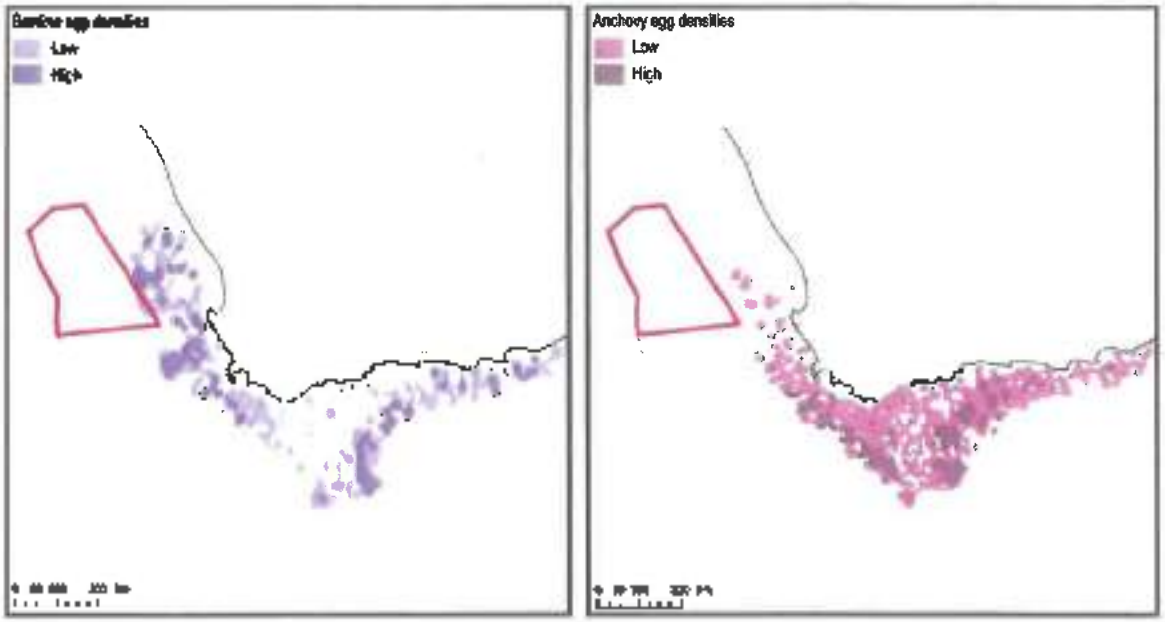

Figure 19: Distribution of sardine (left) and anchovy (right) spawning areas, as measured by egg densities, in relation to the Reconnaissance Permit Area (red polygon) (adapted from Harris *et al.* 2022).

3.3.3.2 Cephalopods

Fourteen species of cephalopds have been recorded in the southern Benguela, the majority of which are sepiods/cuttlefish (Lipinski 1992; Augustyn *et al.* 1995). Most of the cephalopod resource is distributed on the mid-shelf with *Sepia australis* being most abundant at depths between 60-190 m, whereas *S. hieronis* densities were higher at depths between 110-250 m. *Rossia enigmatica* occurs more commonly on the edge of the shelf to depths of 500 m. Biomass of these species was generally higher in the summer than in winter.

Cuttlefish are largely epi-benthic and occur on mud and fine sediments in association with their major prey item; mantis shrimps (Augustyn *et al.* 1995). They form an important food item for demersal fish.

The colossal squid *Mesonychoteuthis hamiltoni* and the giant squid *Architeuthis* sp. may also be encountered in the project area. Both are deep dwelling species, with the colossal squid's distribution confined to the entire circum-antarctic Southern Ocean (Figure 20, top) while the giant squid is usually found near continental and island slopes all around the world's oceans (Figure 20, bottom). Both species could thus potentially occur in the pelagic habitats of the project area, although the likelihood of encounter is extremely low.

Growing to in excess of 10 m in length, they are the principal prey of the sperm whale, and are also taken by beaked whales, pilot whales, elephant seals and sleeper sharks. Nothing is known of their vertical distribution, but data from trawled specimens and sperm whale diving behaviour suggest they may span a depth range of 300 - 1 000 m. They lack gas-filled swim bladders and maintain neutral buoyancy through an ammonium chloride solution occurring throughout their bodies.

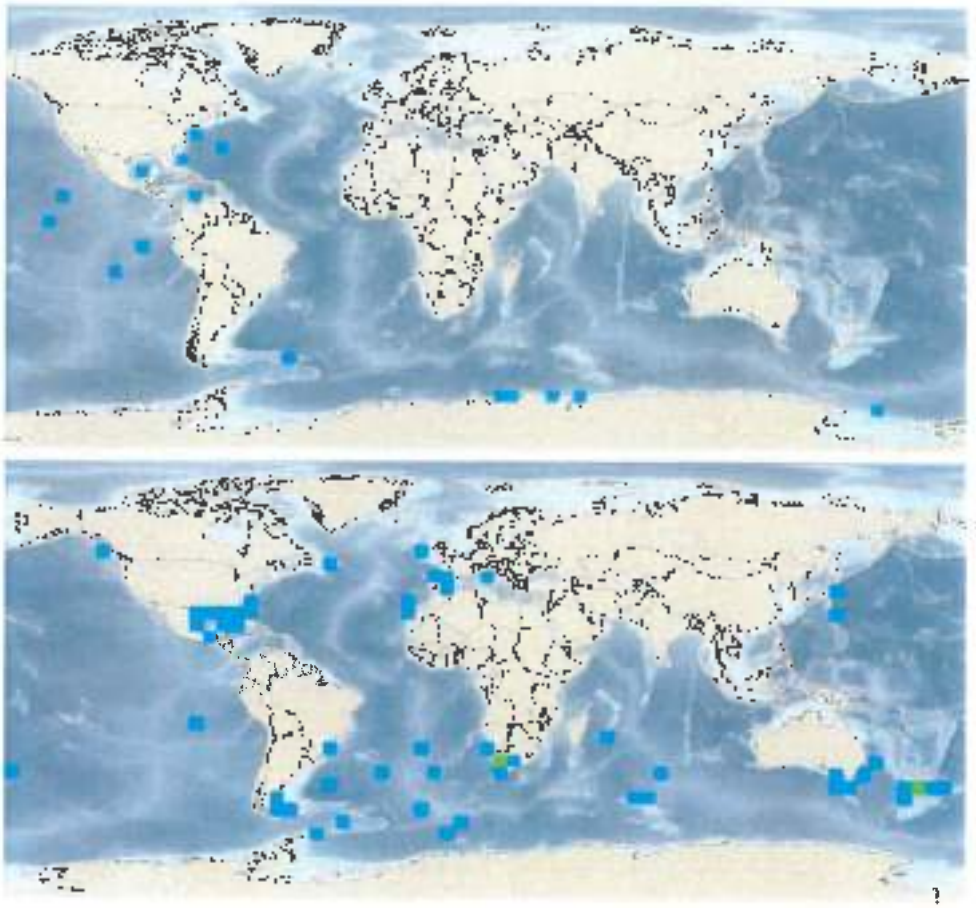

Figure 20: Distribution of the colossal squid (top) and the giant squid (bottom). Blue squares <5 records, green squares 5-10 records (Source: http://iobis.org).

3.3.3.3 *Pelagic Fish*

Small pelagic species include the sardine/pilchard (*Sadinops ocellatus*) (Figure 21, left), anchovy (*Engraulis capensis*), chub mackerel (*Scomber japonicus*), horse mackerel (*Trachurus capensis*) (Figure 21, right) and round herring (*Etrumeus whiteheadi*). These species typically occur in mixed shoals of various sizes (Crawford *et al.* 1987), and generally occur within the 200 m contour and thus likely to only be encountered in southeastern inshore portion of the project area. Most of the pelagic species exhibit similar life history patterns involving seasonal migrations between the west and south coasts. The spawning areas of the major pelagic species are distributed on the continental shelf and along the shelf edge extending from south of St Helena Bay to Mossel Bay on the South Coast (Shannon & Pillar 1986) (see Figure 17). They spawn downstream of major upwelling centres in spring and summer, and their eggs and larvae are subsequently carried around Cape Point and up the coast in northward flowing surface waters.

At the start of winter every year, juveniles of most small pelagic shoaling species recruit into coastal waters in large numbers between the Orange River and Cape Columbine. They recruit in the pelagic stage, across broad stretches of the shelf, to utilise the shallow shelf region as nursery grounds before gradually moving southwards in the inshore southerly flowing surface current, towards the major spawning grounds east of Cape Point. Recruitment success relies on the interaction of oceanographic

events, and is thus subject to spatial and temporal variability. Consequently, the abundance of adults and juveniles of these small, short-lived (1-3 years) pelagic fish is highly variable both within and between species.

Figure 21: Cape fur seal preying on a shoal of pilchards (left). School of horse mackerel (right) (photos: www.underwatervideo.co.za; www.delivery.superstock.com).

Two species that migrate along the West Coast following the shoals of anchovy and pilchards are snoek *Thyrsites atun* and chub mackerel *Scomber japonicas*. Both these species have been rated as 'Least concern' on the national assessment (Sink *et al.* 2019). While the appearance of chub mackerel along the West and South-West coasts is highly seasonal, adult snoek are found throughout their distribution range and longshore movement are random and without a seasonal basis (Griffiths 2002). Initially postulated to be a single stock that undergoes a seasonal longshore migration from southern Angola through Namibia to the South African West Coast (Crawford & De Villiers 1985; Crawford *et al.* 1987), Benguela snoek are now recognised as two separate sub-populations separated by the Lüderitz upwelling cell (Griffiths 2003). On the West Coast, snoek move offshore to spawn and there is some southward dispersion as the spawning season progresses, with females on the West Coast moving inshore to feed between spawning events as spawning progresses. In contrast, those found further south along the western Agulhas Bank remain on the spawning grounds throughout the spawning season (Griffiths 2002) (Figure 22). They are voracious predators occurring throughout the water column, feeding on both demersal and pelagic invertebrates and fish. Chub mackerel similarly migrate along the southern African West Coast reaching South-Western Cape waters between April and August. They move inshore in June and July to spawn before starting the return northwards offshore migration later in the year. Their abundance and seasonal migrations are thought to be related to the availability of their shoaling prey species (Payne & Crawford 1989). The distribution of snoek and chub mackerel therefore lies well inshore of the Reconnaissance Permit Area.

The fish most likely to be encountered on the shelf, beyond the shelf break and in the offshore waters of the proposed 3D survey areas are the large migratory pelagic species, including various tunas, billfish and sharks, many of which are considered threatened by the International Union for the Conservation of Nature (IUCN), primarily due to overfishing (Error! Reference source not found.). Tuna and swordfish are targeted by high seas fishing fleets and illegal overfishing has severely damaged the stocks of many of these species. Similarly, pelagic sharks, are either caught as bycatch in the pelagic tuna longline fisheries, or are specifically targeted for their fins, where the fins are removed and the remainder of the body discarded.

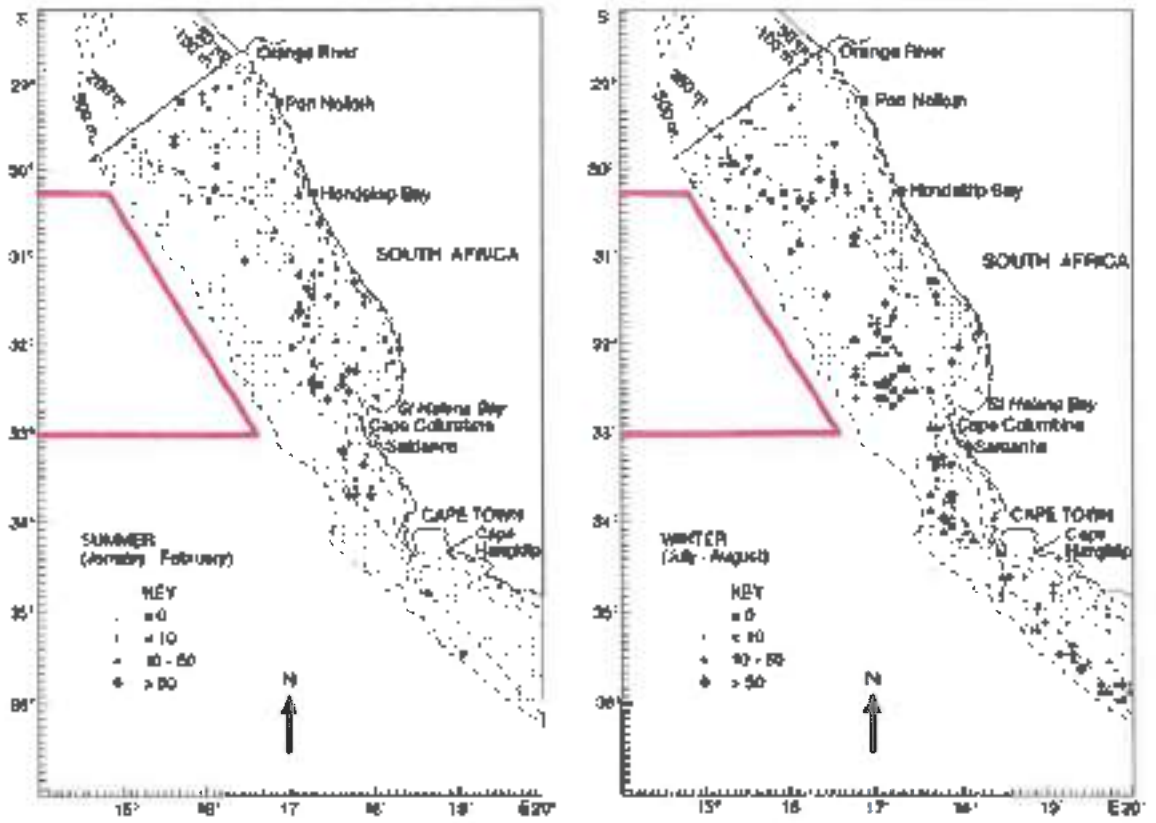

Figure 22: Mean number of snoek per demersal trawl per grid block (5 x 5 Nm) by season for (A) the west coast (July 1985-Jan 1991) and (B) the south coast in relation to the Reconnaissance Permit Area (red polygon) (adapted from Griffiths 2002).

These large pelagic species migrate throughout the southern oceans, between surface and deep waters (>300 m) and have a highly seasonal abundance in the Benguela. Species occurring off western southern Africa include the albacore/longfin tuna *Thunnus alalunga* (Figure 23, right), yellowfin *T. albacares*, bigeye *T. obesus*, and skipjack *Katsuwonus pelamis tunas*, as well as the Atlantic blue marlin *Makaira nigricans* (Figure 23, left), the white marlin *Tetrapturus albidus* and the broadbill swordfish *Xiphias gladius* (Payne & Crawford 1989). The distribution of these species is dependent on food availability in the mixed boundary layer between the Benguela and warm central Atlantic waters. Concentrations of large pelagic species are also known to occur associated with underwater feature such as canyons and seamounts as well as meteorologically induced oceanic fronts (Shannon *et al.* 1989; Penney *et al.* 1992). Seasonal association with Child's Bank and Tripp Seamount occurs between October and June, with commercial catches often peaking in March and April (www.fao.org/fi/fcp/en/ NAM/body.htm; see CapMarine 2022 - Fisheries Specialist Study).

Table 3: Some of the more important large migratory pelagic fish likely to occur in the offshore regions of the West Coast (TOPS list under NEMBA, Act 10 of 2004; Sink *et al.* 2019; www.iucnredlist.org;). The National and Global IUCN Conservation Status are also provided.

Longfin Mako	*Isurus paucus*	Not Assessed	Vulnerable
Whale Shark	*Rhincodon typus*	Not Assessed	Endangered
Blue Shark	*Prionace glauca*	Least concern	Near Threatened

A number of species of pelagic sharks are also known to occur on the West and South-West Coast, including blue *Prionace glauca*, short-fin mako *Isurus oxyrinchus* and oceanic whitetip sharks *Carcharhinus longimanus*. Occurring throughout the world in warm temperate waters, these species are usually found further offshore on the West Coast. Great whites *Carcharodon carcharias* and whale sharks *Rhincodon typus* may also be encountered in coastal and offshore areas, although the latter occurs more frequently along the South and East coasts. The recapture of a juvenile blue shark off Uruguay, which had been tagged off the Cape of Good Hope, supports the hypothesis of a single blue shark stock in the South Atlantic (Hazin 2000; Montealegre-Quijano & Vooren 2010) and Indian Oceans (da Silva et al. 2010). Using the Benguela drift in a north-westerly direction, it is likely that juveniles from the parturition off the south-western Cape would migrate through the project area *en route* to South America (da Silva *et al.* 2010).

The shortfin mako inhabits offshore temperate and tropical seas worldwide. It can be found from the surface to depths of 500 m, and as one of the few endothermic sharks is seldom found in waters <16

°C (Compagno 2001; Loefer *et al.* 2005). As the fastest species of shark, shortfin makos have been recorded to reach speeds of 40 km/h with burst of up to 74 km/h, and can jump to a height of 9 m (http://www.elasmo-research.org/education/shark_profiles/ i_oxyrinchus.htm). Most makos caught by longliners off South Africa are immature, with reports of juveniles and sub-adults sharks occurring near the edge of the Agulhas Bank and off the South Coast between June and November (Groenevald *et al.* 2014), whereas larger and reproductively mature sharks were more common in the inshore environment along the East Coast (Foulis 2013).

Figure 23: Large migratory pelagic fish such as blue marlin (left) and longfin tuna (right) occur in offshore waters (photos: www.samathatours.com; www.osfimages.com).

Whale sharks are regarded as a broad ranging species typically occurring in offshore epipelagic areas with sea surface temperatures of 18-32°C (Eckert & Stewart 2001). Adult whale sharks reach an average size of 9.7 m and 9 tonnes, making them the largest non-cetacean animal in the world. They are slow-moving filter-feeders and therefore particularly vulnerable to ship strikes (Rowat 2007). Although primarily solitary animals, seasonal feeding aggregations occur at several coastal sites all over the world, those closest to the project area being off Sodwana Bay in KwaZulu Natal (KZN) in the Greater St. Lucia Wetland Park (Cliff *et al.* 2007). Satellite tagging has revealed that individuals may travel distances of tens of 1 000s of kms (Eckert & Stewart 2001; Rowat & Gore 2007; Brunnschweiler *et al.* 2009). On the West Coast their summer and winter distributions are centred around the Orange River mouth and between Cape Columbine and Cape Point (Harris *et al.* 2022). The likelihood of an encounter in the offshore waters of the Reconnaissance Permit Area is relatively low.

The whale shark and shortfin mako are listed in Appendix II (species in which trade must be controlled in order to avoid utilization incompatible with their survival) of CITES (Convention on International Trade in Endangered Species) and Appendix I and/or II of the Bonn Convention for the Conservation of Migratory Species (CMS). The whale shark is also listed as 'vulnerable' in the List of Marine Threatened or Protected Species (TOPS) as part of the National Environmental Management: Biodiversity Act (Act 10 of 2004) (NEMBA).

3.3.3.4 Turtles

Three species of turtle occur along the West Coast, namely the Leatherback (*Dermochelys coriacea*) (Figure 24, left), and occasionally the Loggerhead (*Caretta caretta*) (Figure 24, right) and the Green (*Chelonia mydas*) turtle. Loggerhead and Green turtles are expected to occur only as occasional visitors along the West Coast. The most recent conservation status, which assessed the species on a sub-regional scale, is provided in Table 4.

The Leatherback is the only turtle likely to be encountered in the offshore waters of west South Africa. The Benguela ecosystem, especially the northern Benguela where jelly fish numbers are high, is increasingly being recognized as a potentially important feeding area for leatherback turtles from several globally significant nesting populations in the south Atlantic (Gabon, Brazil) and south east Indian Ocean (South Africa) (Lambardi *et al.* 2008, Elwen & Leeney 2011; SASTN 2011[2]). Leatherback turtles from the east South Africa population have been satellite tracked swimming around the west coast of South Africa and remaining in the warmer waters west of the Benguela ecosystem (Lambardi *et al.* 2008) (Figure 25).

Figure 24: Leatherback (left) and loggerhead turtles (right) occur along the West Coast of Southern Africa (Photos: Ketos Ecology 2009; www.aquaworld-crete.com).

Table 4: Global and Regional Conservation Status of the turtles occurring off the South Coast showing variation depending on the listing used.

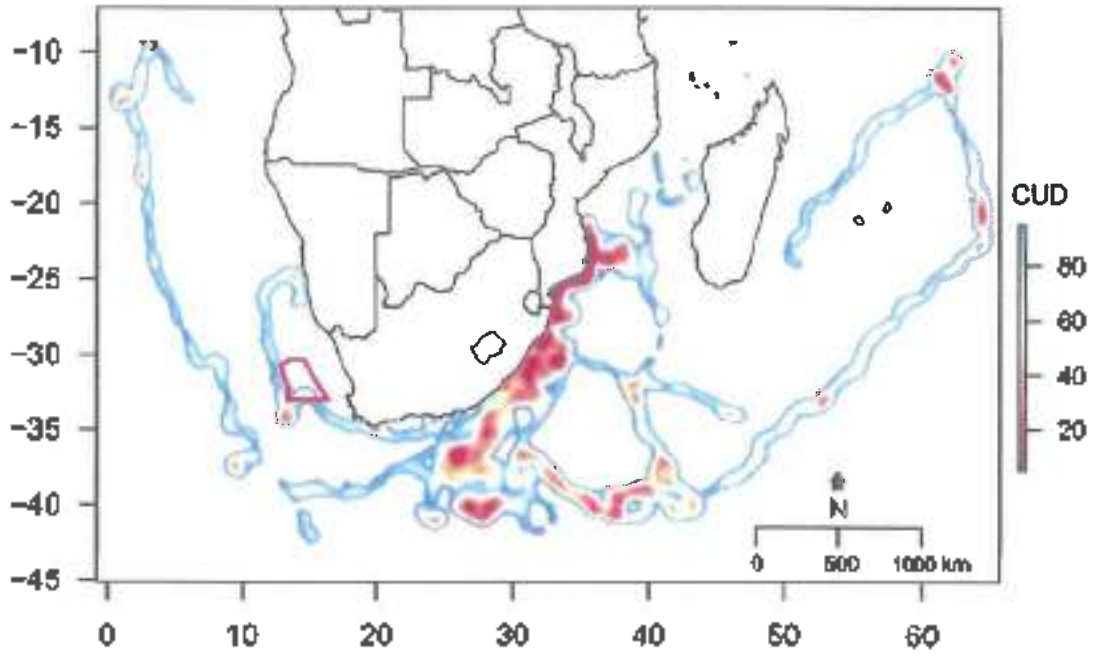

Figure 25: The Reconnaissance Permit Area (red polygon) in relation to the migration corridors of leatherback turtles in the south-western Indian Ocean. Relative use (CUD, cumulative utilization distribution) of corridors is shown through intensity of shading: light, low use; dark, high use (adapted from Harris *et al.* 2018).

Leatherback turtles inhabit deeper waters and are considered a pelagic species, travelling the ocean currents in search of their prey (primarily jellyfish). While hunting they may dive to over 600 m and remain submerged for up to 54 minutes (Hays *et al.* 2004). Their abundance in the study area is unknown but expected to be low. Leatherbacks feed on jellyfish and are known to have mistaken plastic marine debris for their natural food. Ingesting this can obstruct the gut, lead to absorption of toxins and reduce the absorption of nutrients from their real food. Leatherback Turtles are listed as 'Critically Endangered' worldwide by the IUCN and are in the highest categories in terms of need for conservation in CITES (Convention on International Trade in Endangered Species), and CMS (Convention on Migratory Species). The 2017 South African list of Threatened and Endangered Species (TOPS) similarly lists the species as 'Critically Endangered', whereas on the National Assessment (Hughes & Nel 2014) leatherbacks were listed as 'Endangered', whereas Loggerhead and green turtles are listed globally as 'Vulnerable' and 'Endangered', respectively, whereas on TOPS both species are listed as 'Endangered'. As a signatory of CMS, South Africa has endorsed and signed a CMS International Memorandum of Understanding specific to the conservation of marine turtles. South Africa is thus committed to conserve these species at an international level.

3.3.3.5 Seabirds

Large numbers of pelagic seabirds exploit the pelagic fish stocks of the Benguela system. Of the 49 species of seabirds that occur in the Benguela region, 14 are defined as resident, 10 are visitors from the northern hemisphere and 25 are migrants from the southern Ocean. The species classified as being common in the southern Benguela are listed in Table 5. The area between Cape Point and the Orange River supports 38% and 33% of the overall population of pelagic seabirds in winter and summer, respectively. Most of the species in the region reach highest densities offshore of the shelf break (200 - 500 m depth), with highest population levels during their non-breeding season (winter). Pintado petrels and Prion spp. Show the most marked variation here. Pelagic seabird species are therefore likely to be relatively frequently encountered in the offshore waters of the Reconnaissance Permit Area.

Fifteen species of seabirds breed in southern Africa; Cape Gannet (Figure 26, left), African Penguin (Figure 26, right), four species of Cormorant, White Pelican, three Gull and four Tern species (Table 6). The breeding areas are distributed around the coast with islands being especially important. The closest breeding islands to the Reconnaissance Permit Area are Bird Island in Lambert's Bay, the Saldanha Bay Islands and Dassen Island, which lie approximately 192 km,126 km and 150 km to the east and south east of the eastern and southern boundary of the Reconnaissance Permit Area, respectively. The number of successfully breeding birds at the particular breeding sites varies with food abundance. Most of the breeding seabird species forage at sea with most birds being found relatively close inshore (10-30 km). Cape Gannets, which breed at only three locations in South Africa (Bird Island Lamberts Bay, Malgas Island and Bird Island Algoa Bay) are known to forage within 200 km offshore (Dundee 2006; Ludynia 2007; Grémillet *et al.* 2008; Crawford *et al.* 2011), and African Penguins have also been recorded as far as 60 km offshore. The proposed 3D survey area lies well offshore of the aggregate core home ranges of Cape Gannet and African Penguin (Figure 27) (BirdLife South Africa 2022). Aggregate core home ranges and foraging areas for Cape Cormorant and Bank Cormorant similarly lie well inshore of the Reconnaissance Permit Area (see Harris *et al.* 2022). There is, however, overlap of the foraging areas of Wandering Albatross and Atlantic Yellow-nosed Albatross with the Reconnaissance Permit Area (Figure 27) (BirdLife South Africa 2022; Harris *et al.* 2022).

Figure 26: Cape Gannets *Morus capensis* (left) (Photo: NACOMA) and African Penguins *Spheniscus demersus* (right) (Photo: Klaus Jost) breed primarily on the offshore islands.

Interactions with commercial fishing operations, either through incidental bycatch or competition for food resources, are the greatest threat to southern African seabirds, impacting 56% of seabirds of special concern. Crawford *et al.* (2014) reported that four of the seabirds assessed as 'Endangered' compete with South Africa's fisheries for food: African Penguins, Cape Gannets and Cape Cormorants for sardines and anchovies, and Bank Cormorants for rock lobsters (Crawford *et al.* 2015). Populations of seabirds off the West Coast have recently shown significant decreases, with the population numbers of African Penguins currently only 2.5% of what the population was 80 years ago; declining from 1 million breeding pairs in the 1920s, 25 000 pairs in 2009 and 15 000 in 2018 (Sink *et al.* 2019). For Cape Gannets, the global population decreased from about 250 000 pairs in the 1950s and 1960s to approximately 130 000 in 2018, primarily as a result of a >90% decrease in Namibia's population in response to the collapse of Namibia's sardine resource. In South Africa, numbers of Cape Gannets have increased since 1956 and South Africa now holds >90% of the global population. However, numbers have recently decreased in the Western Cape but increased in Algoa Bay mirroring the southward and eastward shift sardine and anchovy. Algoa Bay currently holds approximately 75% of the South African Gannet population.

Cape cormorants and Bank cormorants showed a substantial decline from the late 1970s/early 1980s to the late 2000s/early 2010s, with numbers of Cape cormorants dropping from 106 500 to 65 800 breeding pairs, and Bank cormorants from 1 500 to only 800 breeding pairs over that period (Crawford *et al.* 2015).

Demersal and pelagic longlining are key contributors to the mortality of albatrosses (Browed albatross 7%, Indian and Atlantic Yellow-Nosed Albatross 3%), petrels (white-chinned petrel 66%), shearwaters and Cape Gannets (2%) through accidental capture (bycatch and/or entanglement in fishing gear), with an estimated annual mortality of 450 individuals of 14 species for the period 2006 to 2013 (Rollinson *et al.* 2017). Other threats include predation by mice on petrel and albatross chicks on sub-Antarctic islands, predation of chicks of Cape, Crowned and Bank Cormorants by Great White

628

Pelicans, and predation of eggs and chicks of African Penguins, Bank, Cape and Crowned Cormorants by Kelp gulls. Disease (avian flu), climate change (heat stress and environmental variability) and oil spills are also considered major contributors to seabird declines (Sink *et al.* 2019).

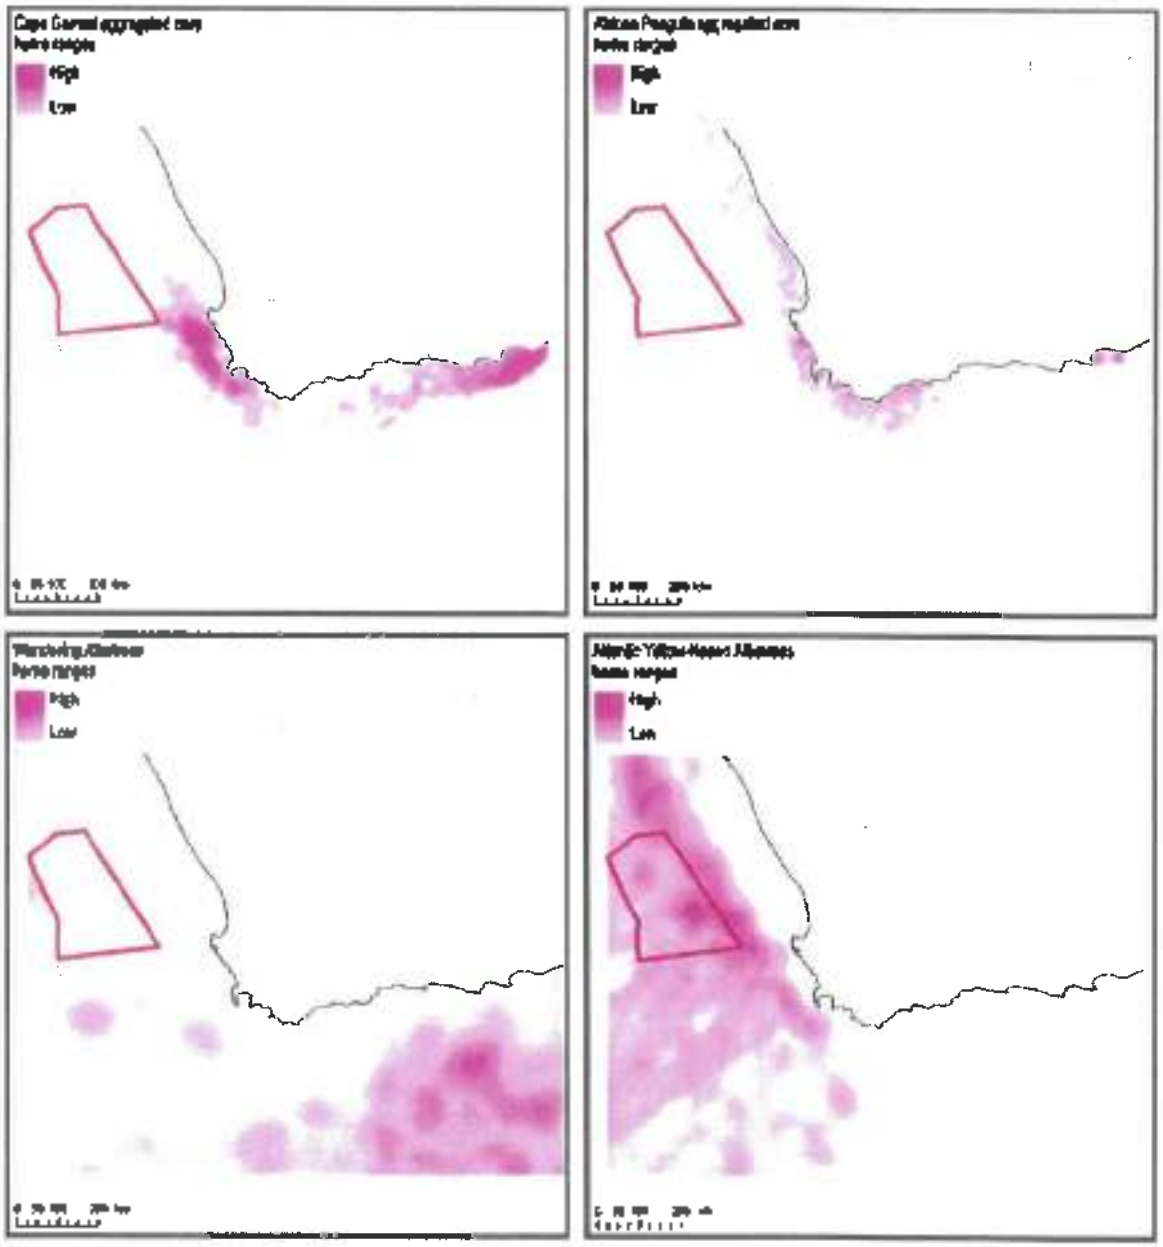

Figure 27: The Reconnaissance Permit Area (red polygon) in relation to aggregate core home ranges of Cape Gannet (top left), African Penguin (top right) for different colonies and life-history stages, and foraging areas of Wandering Albatross (bottom left) and Atlantic Yellow-nosed Albatross (bottom right). For foraging areas, darker shades are areas of higher use and where foraging areas from different colonies overlap (adapted from Harris *et al.* 2022).

3.3.3.6 *Marine Mammals*

The marine mammal fauna occurring off the southern African coast includes several species of whales and dolphins and one resident seal species. Thirty three species of whales and dolphins are known (based on historic sightings or strandings records) or likely (based on habitat projections of known species parameters) to occur in these waters (Table 7). Of the species listed, the blue whale is considered 'Critically Endangered', fin and sei whales are 'Endangered' and one is considered vulnerable (IUCN Red Data list Categories). Altogether 17 species are listed as 'data deficient' underlining how little is known about cetaceans, their distributions and population trends. The offshore areas have been particularly poorly studied with most available information from deeper waters (>200 m) arising from historic whaling records prior to 1970. In the past ten years, passive acoustic monitoring and satellite telemetry have begun to shed light on current patterns of seasonality and movement for some large whale species (Best *et al.* 2009; Elwen *et al.* 2011; Rosenbaum *et al.* 2014; Shabangu *et al.* 2019; Thomisch *et al.* 2019) but information on smaller cetaceans in deeper waters remains poor. Records from marine mammal observers on seismic survey vessels have provided valuable data into cetacean presence although these are predominantly during summer months (Purdon *et al.* 2020). Information on general distribution and seasonality is improving but data population sizes and trends for most cetacean species occurring on the west coast of southern Africa is lacking.

The 3D acquisition area extends from the Namibian border to 32°27' offshore of St Helena Bay from roughly the 500 m isobath to nearly 4 000 m water depth. Oceanographically this area lies largely outside the cool waters of the Benguela Ecosystem and receives some input from the warm Agulhas Current as well as the warm waters of the South Atlantic. In terms of cetacean distribution patterns, the area thus covers a broad range of habitats and species associated with each of those water masses may occur within the target area. Records from stranded specimens show that the area between St Helena Bay (~32° S) and Cape Agulhas (~34° S, 20° E) is an area of transition between Atlantic and Indian Ocean species, and includes records from Benguela associated species such as dusky dolphins, Heaviside's dolphins and long finned pilot whales, and those of the warmer east coast such as striped and Risso's dolphins (Findlay *et al.* 1992). Species such as rough toothed dolphins, Pan-tropical spotted dolphins and short finned pilot whales are known from the southern Atlantic. Owing to the uncertainty of species occurrence offshore, species that may occur there have been included here for the sake of completeness.

The distribution of cetaceans can largely be split into those associated with the continental shelf and those that occur in deep, oceanic water. Importantly, species from both environments may be found on the continental slope (200 - 2 000 m) making this the most species rich area for cetaceans and also high in density (De Rock *et al.* 2019, SLR data). Cetacean density on the continental shelf is usually higher than in pelagic waters as species associated with the pelagic environment tend to be wide ranging across 1 000s of km. The most common species within the project area (in terms of likely encounter rate not total population sizes) are likely to be the long-finned pilot whale, Risso's dolphin, common dolphin, sperm whale (winter distribution) and humpback whale (Figure 28) (Harris *et al.* 2022).

Cetaceans are comprised of two taxonomic groups, the mysticetes (filter feeders with baleen) and the odontocetes (predatory whales and dolphins with teeth). The term 'whale' is used to describe species in both groups and is taxonomically meaningless (e.g. the killer whale and pilot whale are members of the Odontoceti, family Delphinidae and are thus dolphins). Due to differences in

sociality, communication abilities, ranging behavior and acoustic behavior, these two groups are considered separately.

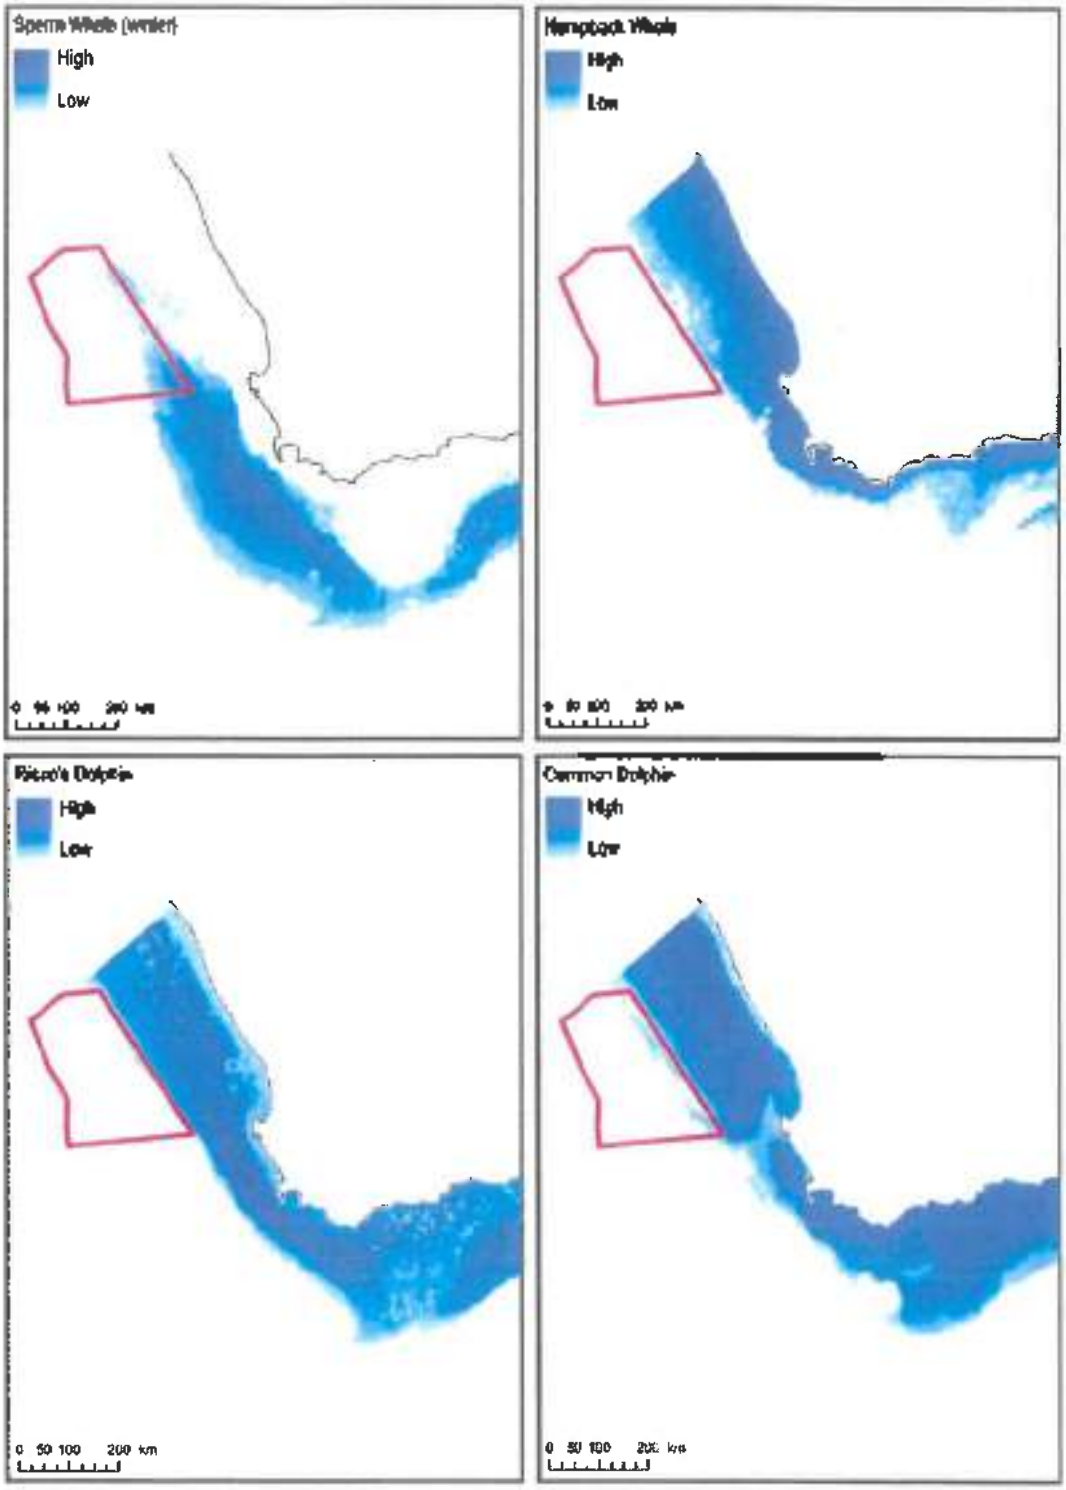

Figure 28: The Reconnaissance Permit Area (red polygon) in relation to the predicted distribution of Sperm whales (winter distribution)(left), humpback whale (middle) and Risso's dolphin (right) with darker shades of blue indicating highest likelihood of occurrence (adapted from Harris et al. 2022).

Table 7 lists the cetaceans likely to be found within the project area, based on all available data sources but mainly: Findlay *et al.* (1992), Best (2007), Weir (2011), De Rock *et al.* (2019), Purdon *et al.* (2020a, 2020b, 2020c), and unpublished records held by Sea Search and those held by SLR consulting and shared for this report (see also Figure 29a-b, Figure 30). The majority of data available on the seasonality and distribution of large whales in the project area is the result of commercial whaling activities mostly dating from the 1960s. Changes in the timing and distribution of migration may have occurred since these data were collected due to extirpation of populations or behaviours (e.g. migration routes may be learnt behaviours). The large whale species for which there are current data available are the humpback and southern right whale, although almost all data is limited to that collected on the continental shelf close to shore. A review of the distribution and seasonality of the key cetacean species likely to be found within the project area is provided below.

Mysticete (Baleen) whales

The majority of mysticetes whales fall into the family Balaenopeteridae. Those occurring in the area include the blue, fin, sei, Antarctic minke, dwarf minke, humpback and Bryde's whales. The southern right whale (Family Balaenidae) and pygmy right whale (Family Neobalaenidae) are from taxonomically separate groups. The majority of mysticete species occur in pelagic waters with only occasional visits to shelf waters. All of these species show some degree of migration either to or through the latitudes encompassed by the broader project area when *en route* between higher latitude (Antarctic or Subantarctic) feeding grounds and lower latitude breeding grounds.

Depending on the ultimate location of these feeding and breeding grounds, seasonality may be either unimodal, usually in winter months, or bimodal (e.g. May to July and October to November), reflecting a northward and southward migration through the area. Northward and southward migrations may take place at different distances from the coast due to whales following geographic or oceanographic features, thereby influencing the seasonality of occurrence at different locations. Because of the complexities of the migration patterns, each species is discussed separately below.

Bryde's whales: Two genetically and morphologically distinct populations of Bryde's whales (Figure 31, left) live off the coast of southern Africa (Best 2001; Penry 2010). The "offshore population" lives beyond the shelf (>200 m depth) off west Africa and migrates between wintering grounds off equatorial west Africa (Gabon) and summering grounds off western South Africa. Its seasonality on the West Coast is thus opposite to the majority of the balaenopterids with abundance likely to be highest in the area in January - March. The "inshore population" of Bryde's whale live mainly on the continental shelf and Agulhas Bank, and are unique amongst baleen whales in the region by being non-migratory. The inshore population has recently been recognised as its own (yet to be named) sub species (*Balaenoptera brydei edemf*, Penry *et al.* 2018) with a total population for this subspecies of likely fewer than 600 individuals. The published range of the population is the continental shelf and Agulhas Bank of South Africa ranging from Durban in the east to at least St Helena Bay off the west coast with possible movements further north up the West Coast and into Namibia during the winter months (Best 2007). The offshore stock was subjected to heavy whaling in the mid-20th century (Best 2001) and there are no current data on population size or stock recovery therefrom and is currently listed as 'Data deficient' on the South African Red List. The inshore stock is regarded as extremely 'Vulnerable' and listed as such on the South African red list as it regularly suffers losses from entanglement in trap fisheries and has been subject to significant changes in its prey base due to losses and shifts in the sardine and small pelgic stocks around South Africa.

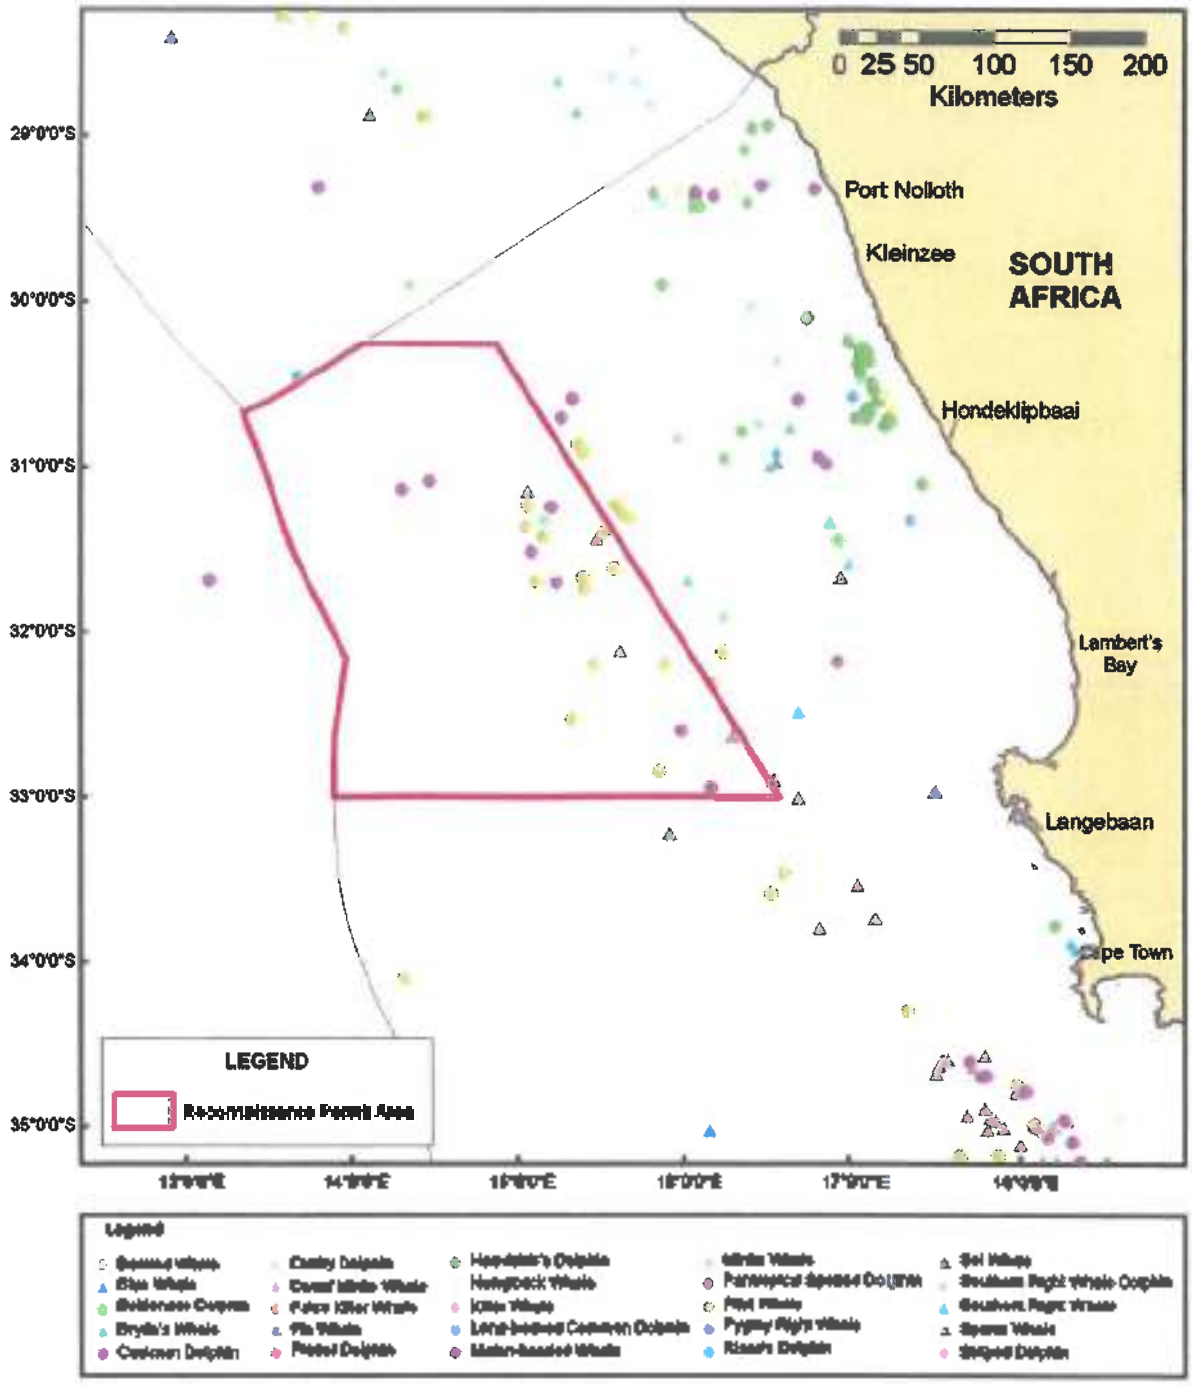

Figure 29a: The Reconnaissance Permit Area (red polygon) in relation to the distribution and movement of cetaceans along the West Coast collated between 2001 and 2020 (SLR MMO database).

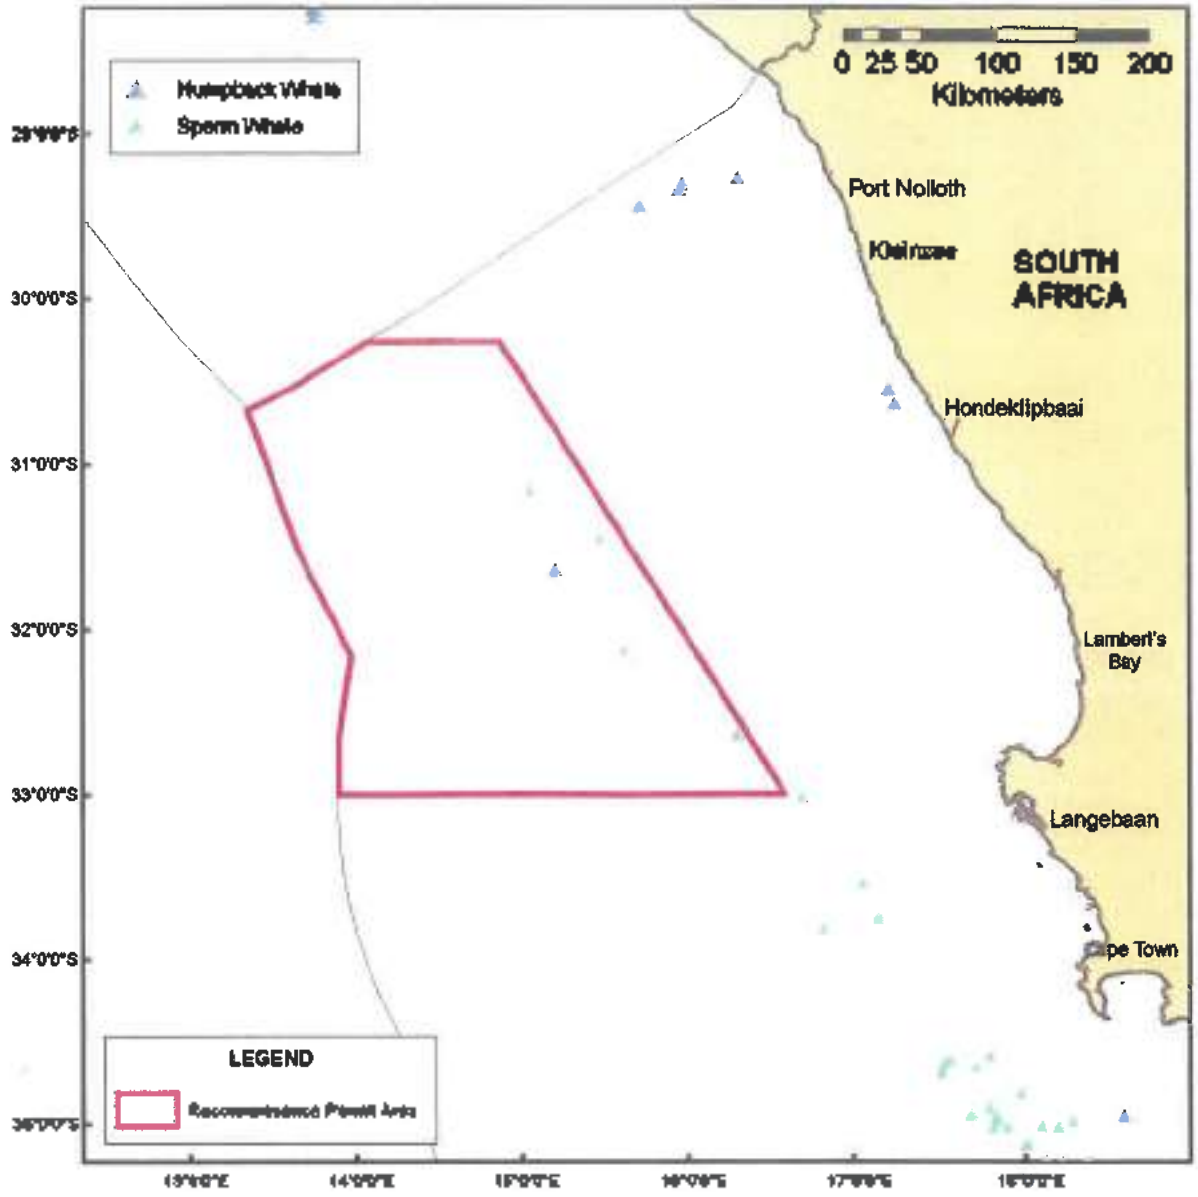

Figure 29b: The Reconnaissance Permit Area (red polygon) in relation to the distribution and movement of Humpback whales and Sperm whales along the West Coast collated between 2001 and 2020 (SLR MMO database).

Sei whales: Almost all information is based on whaling records 1958-1963, most from shore-based catchers operating within a few hundred kilometres of Saldanha Bay. At this time the species was not well differentiated from Bryde's whales and records and catches of the two species intertwined. There is no current information on population recovery, abundance or much information on distribution patterns outside of the whaling catches and the species remains listed as 'Endangered' on the SA Red List. Sei whales feed at high latitudes (40-50°S) during summer months and migrate north through South African waters to unknown breeding grounds further north (Best 2007). Their migration pattern thus shows a bimodal peak with numbers west of Saldanha Bay being highest in May and June, and again in August, September and October. All whales were caught in waters

Table 7: Cetaceans occurrence off the West Coast of South Africa, their seasonality, likely encounter frequency with proposed exploration activities and South African (Child *et al.* 2016) and Global IUCN Red List conservation status.

- Marine animals do not hear equally well at all frequencies within their functional hearing range. Based on the hearing range and sensitivities, Southall *et al.* (2019) have categorised noise sensitive marine mammal species into six underwater hearing groups: low-frequency (LF), high-frequency (HF) and very high-frequency (VHF) cetaceans, Sirenians (SI), Phocid carnivores in water (PCW) and other marine carnivores in water (OCW).

Table 8: Seasonality of baleen whales in the broader project area based on data from multiple sources, predominantly commercial catches (Best 2007 and other sources) and data from stranding events (NDP unpubl data). Values of high (H), Medium (M) and Low (L) are relative within each row (species) and not comparable between species. For abundance / likely encounter rate within the broader project area, see Table 9.

946

deeper than 200 m with most deeper than 1 000 m (Best & Lockyer 2002). A recent survey to Vema Seamount ~1 000 km west of Cape Town during Oct-Nov 2019, encountered a broadly spread feeding aggregation of over 30 sei and fin whales at around 200 m water depth (Elwen *et al.* in prep.). This poorly surveyed area (roughly 32°S, 15°E) is just to the NW of the historic whaling grounds suggesting this region remains an important feeding area for the species. This region lies well within the impact area of the proposed 3D seismic survey and caution is recommended to reduce impacts on this endangered and poorly known species.

Figure 31: The Bryde's whale *Balaenoptera brydei* (left) and the Minke whale *Balaenoptera bonaerensis* (right) (Photos: www.dailymail.co.uk; www.marineblo.org).

Fin whales: Fin whales were historically caught off the West Coast of South Africa, with a bimodal peak in the catch data suggesting animals were migrating further north during May-June to breed, before returning during August-October en route to Antarctic feeding grounds. However, the location of the breeding ground (if any) and how far north it is remains a mystery (Best 2007). Some juvenile animals may feed year round in deeper waters off the shelf (Best 2007). Aggregations of up to eight animals have been seen on multiple occasions on the coast either side of Lüderitz in Apr-May of 2014 and January 2015 (Sea Search unpubl. Data), the occasional single whale has been reported during humpback whale research in November in the southern Benguela, and a feeding aggregation of ~30 animals was observed in November 2019 ~200 km west of St Helena Bay in ~2 000 m of water (see above). Current sightings records support the bimodal peak in presence observed from whaling data (but with some chance of year-round sightings) with animals apparently feeding in the nutrient rich Benguela during their southward migration as is observed extensively for humpback and right whales (see below) there clearly is a chance of encounters year round. There are no recent data on abundance or distribution of fin whales off western South Africa.

Blue whales: Although Antarctic blue whales were historically caught in high numbers off the South African West Coast, with a single peak in catch rates during July in Namibia and Angola suggesting that these latitudes are close to the northern migration limit for the species in the eastern South Atlantic (Best 2007). Although there were only two confirmed sightings of the species in the area between 1973 and 2006 (Branch *et al.* 2007), evidence of blue whale presence off Namibia is increasing. Recent acoustic detections of blue whales in the Antarctic peak between December and January (Townsch *et al.* 2016), off western South Africa (Shanbangu *et al.* 2019) and in northern Namibia between May and July (Thomisch 2017) supporting observed timing from whaling records. Several recent (2014-2015) sightings of blue whales during seismic surveys off the southern part of Namibia (water depth >1 000 m) confirm their existence in the area and occurrence in Autumn

months. The chance of encountering the species in the proposed survey area is considered low but the species is 'Critically Endangered' so all precautions must be taken to avoid impact.

Minke whales: Two forms of minke whale (Figure 31, right) occur in the southern Hemisphere, the Antarctic minke whale (*Balaenoptera bonaerensis*) and the dwarf minke whale (*B. acutorostrata* subsp.); both species occur in the Benguela (Best 2007). Antarctic minke whales range from the pack ice of Antarctica to tropical waters and are usually seen more than ~50 km offshore. Although adults migrate from the Southern Ocean (summer) to tropical/temperate waters (winter) to breed, some animals, especially juveniles, are known to stay in tropical/temperate waters year-round. Recent data available from passive acoustic monitoring over a two-year period off the Walvis Ridge shows acoustic presence in June - August and November - December (Thomisch *et al.* 2016), supporting a bimodal distribution in the area. The dwarf minke whale has a more temperate distribution than the Antarctic minke and they do not range further south than 60-65°S. Dwarf minkes have a similar migration pattern to Antarctic minkes with at least some animals migrating to the Southern Ocean during summer. Dwarf minke whales occur closer to shore than Antarctic minkes and have been seen <2 km from shore on several occasions around South Africa. Both species are generally solitary and densities are likely to be low in the project area, although sightings have been reported (SLR data).

The pygmy right whale is the smallest of the baleen whales reaching only 6 m total length as an adult (Best 2007). The species is typically associated with cool temperate waters between 30°S and 55°S with records from southern and central Namibia being the northern most for the species (Leeney *et al.* 2013). Its distribution off the west coast of South Africa is thus likely to be limited to the cooler shelf waters of the main Benguela upwelling areas.

The most abundant baleen whales in the Benguela are southern right whales and humpback whales (Figure 32a & b). Both species have long been known to feed in the Benguela Ecosystem and numbers since 2000 have grown substantially. The feeding peak in the Benguela is spring and early summer (October - February) and follows the 'traditional' South African breeding season (June - November) and its' associated migrations (Johnson *et al.* 2022). Some individual right whales are known to move directly from the south coast breeding area into the west coast feeding area where they remained for several months (Barendse *et al.* 2011; Mate *et al.* 2011). Increasing numbers of summer records of both species, from the southern half of Namibia suggest that animals may also be feeding in the Lüderitz upwelling cell (NDP unpubl. Data).

Humpback whales: The majority of humpback whales passing through the Benguela are migrating to breeding grounds off tropical west Africa, between Angola and the Gulf of Guinea (Rosenbaum *et al.* 2009; Barendse *et al.* 2010). Until recently it was believed that that these breeding grounds were functionally separate from those off east (Mozambique-Kenya-Madagascar), with only rare movements between them (Pomilla & Rosenbaum 2005) and movements to other continental breeding grounds being even more rare. Recent satellite tagging of animals between Plettenberg Bay and Port Alfred during the northward migration, showed them to turn around and end up feeding in the Southern Benguela (Seakamela *et al.* 2015) before heading offshore and southwards using the same route as whales tracked off Gabon and the West Coast of South Africa. Unexpected results such as this highlight the complexities of understanding whale movements and distribution patterns and the fact that descriptions of broad season peaks in no way captures the wide array of behaviours exhibited by these animals. Furthermore, three separate matches have been made between individuals off South Africa and Brazil by citizen scientist photo-identification (www.happywhale.com). This included whales from the Cape Town and Algoa Bay-Transkei areas. Analysis of humpback whale breeding song

BW25

on Sub-Antarctic feeding grounds also suggests exchange of singing male whales from western and eastern South Atlantic populations (Darling & Sousa-Lima 2005; Schall *et al.* 2021; but see also Darling *et al.* 2019; Tyarks *et al.* 2021).

Figure 32: The Humpback whale *Megaptera novaeangliae* (left) and the Southern Right whale *Eubalaena australis* (right) are the most abundant large cetaceans occurring along the southern African West Coast (Photos: www.divephotoguide.com; www.aad.gov.au).

In southern African coastal waters, the northward migration stream is larger than the southward peak (Best & Allison 2010; Elwen *et al.* 2014), suggesting that animals migrating north strike the coast at varying places north of St Helena Bay, resulting in increasing whale density on shelf waters and into deeper pelagic waters as one moves northwards. On the southward migration, many humpbacks follow the Walvis Ridge offshore then head directly to high latitude feeding grounds, while others follow a more coastal route (including the majority of mother-calf pairs) possibly lingering in the feeding grounds off west South Africa in summer (Elwen *et al.* 2014; Rosenbaum *et al.* 2014). Although migrating through the Benguela, there is no existing evidence of a clear 'corridor' and humpback whales appear to be spread out widely across the shelf and into deeper pelagic waters, especially during the southward migration (Barendse *et al.* 2010; Best & Allison 2010; Elwen *et al.* 2014). The only available abundance estimate put the number of animals in the West African breeding population (Gabon) to be in excess of 9 000 individuals in 2005 (IWC 2012) and it is likely to have increased substantially since this time at about 5% per annum (IWC 2012; see also Wilkinson 2021). The number of humpback whales feeding in the southern Benguela has increased substantially since estimates made in the early 2000s (Barendse *et al.* 2011). Since ~2011, 'supergroups' of up to 200 individual whales have been observed feeding within 10 km from shore (Findlay *et al.* 2017) with many hundred more passing through and whales are now seen in all months of the year around Cape Town. It has been suggested that the formation of these super-groups may be in response to anomalous oceanographic conditions in the Southern Benguela, which result in favourable food availability, thereby leading to these unique humpback whale feeding aggregations (Dey *et al.* 2021; see also Avila *et al.* 2019; Meynecke *et al.* 2020; Cade *et al.* 2021). Humpback whales are thus likely to be the most frequently encountered baleen whale in the project area (see Figure 29b), ranging from the coast out beyond the shelf, with year round presence but numbers peaking during the northward migration in June - February and a smaller peak with the southern breeding migration around September - October but with regular encounters until February associated with subsequent feeding in the Benguela ecosystem.

In the first half of 2017 (when numbers are expected to be at their lowest) more than 10 humpback whales were reported stranded along the Namibian and South African west coasts. A similar event was recorded in late 2021-early 2022 when numerous strandings of young humpbacks were reported along the Western Cape Coast and in Namibia (Simon Elwen, Sea Search, pers. Comm.). The cause of these deaths is not known, but a similar event off Brazil in 2010 (Siciliano *et al.* 2013) was linked to possible infectious disease or malnutrition. Unusual mortality events of humpback whales between 2016 and 2022 have similarly been reported along the US Atlantic Coast from Maine to Florida (https://www.fisheries.noaa.gov/national/marine-life-distress/2016-2022-humpback-whale-unusual-mortality-event-along-atlantic-coast). The West African population may be undergoing similar stresses in response to changes in their ecosystem (see for example Kershaw *et al.* 2021). It is not yet understood what may be driving these ecosystem changes and what the long-term effects to populations could potentially be.

Southern right whales: The southern African population of southern right whales historically extended from southern Mozambique (Maputo Bay) to southern Angola (Baie dos Tigres) and is considered to be a single population within this range (Roux *et al.* 2011). The most recent abundance estimate for this population is available for 2017 which estimated the population at ~6 100 individuals including all age and sex classes, and still growing at ~6.5% per annum (Brandão *et al.* 2017). When the population numbers crashed in 1920, the range contracted down to just the south coast of South Africa, but as the population recovers, it is repopulating its historic grounds including Namibia (Roux *et al.* 2001, 2015; de Rock *et al.* 2019) and Mozambique (Banks *et al.* 2011).

Some southern right whales move from the South Coast breeding ground directly to the West Coast feeding ground (Mate *et al.* 2011). When departing from feeding ground all satellite tagged animals in that study took a direct south-westward track. Mark-recapture data from 2003-2007 estimated roughly one third of the South African right whale population at that time were using St Helena Bay for feeding (Peters *et al.* 2005). While annual surveys have revealed a steady population increase since the protection of the species from commercial whaling, the South African right whale population has undergone substantial changes in breeding cycles and feeding areas (Van Den Berg *et al.* 2020), and numbers of animal using our coast since those studies were done - notably a significant decrease in the numbers of cow-calf-pairs following the all-time record in 2018, a marked decline of unaccompanied adults since 2010 and variable presence of mother-calf pairs since 2015 (Roux *et al.* 2015; Vermeulen *et al.* 2020). The change in demographics are indications of a population undergoing nutritional stress and has been attributed to likely spatial and/or temporal displacement of prey due to climate variability (Vermeulen *et al.* 2020; see also Derville *et al.* 2019, 2020; Kershaw *et al.* 2021; van Weelden *et al.* 2021). Recent sightings (2018-2021) confirm that there is still a clear peak in numbers on the West Coast (Table Bay to St Helena Bay) between February and April. Given this high proportion of the population known to feed in the southern Benguela, and current numbers reported, it is highly likely that several hundreds of right whales can be expected to pass through the southern portion of the Reconnaissance Permit Area when migrating southwards from the feeding areas between April and June (Figure 33).

Figure 33: The Reconnaissance Permit Area (red polygon) in relation to 'blue corridors' or 'whale superhighways' showing tracks of Humpback whales (orange) and Southern Right whales (green) between southern Africa and the Southern Ocean feeding grounds (adapted from Johnson et al. 2022).

Odontocetes (toothed) whales

The Odontoceti are a varied group of animals including the dolphins, porpoises, beaked whales and sperm whales. Species occurring within the broader project area display a diversity of features, for example their ranging patterns vary from extremely coastal and highly site specific to oceanic and wide ranging (see Figure 30). Those in the region can range in size from 1.6-m long (Heaviside's dolphin) to 17 m (bull sperm whale).

Sperm whales: Most information about sperm whales in the southern African sub-region results from data collected during commercial whaling activities prior to 1985 when over 10 000 whales were taken, (Best 1974, Best 2007) although passive acoustic monitoring (Shabangu & Andrew 2020) and sightings from NMOs are beginning to provide insights into current behaviour. Sperm whales are the Largest of the toothed whales and have a complex, structured social system with adult males behaving differently to younger males and female groups. They live in deep ocean waters, usually greater than 1 000 m depth, although they occasionally come onto the shelf in water 500 - 200 m deep (Best, 2007)

(Figure 34, left). They are considered to be relatively abundant globally (Whitehead 2002), although no estimates are available for South African waters. Seasonality of catches suggests that medium and large sized males are more abundant in winter months while female groups are more abundant in autumn (March - April), although animals occur year round (Best, 2007). Analysis of recent passive acoustic monitoring data from the edge of the continental shelf (800 - 1 000 m water depth, roughly 80 km WSW of Cape Point) confirms year-round presence. Sperm whales have also been regularly identified by MMOs working in this area (SLR data). Sperm whales feed at great depths during dives in excess of 30 minutes making them difficult to detect visually, however the regular echolocation clicks made by the species when diving make them relatively easy to detect acoustically using Passive Acoustic Monitoring (PAM).

Figure 34: Sperm whales *Physeter macrocephalus* (left) and killer whales *Orcinus orca* (right) are toothed whales likely to be encountered in offshore waters (Photos: www.onpoint.wbur.org; www.wikipedia.org).

Pygmy and Dwarf Sperm Whales: The genus *Kogia* currently contains two recognised species, the pygmy (*K. breviceps*) and dwarf (*K. sima*) sperm whales, both of which occur worldwide in pelagic and shelf edge waters, with with few sighting records of live animals in their natural habitat (McAlpine 2018). Their abundance, population trends and seasonality in South African waters are unknown (Seakamela *et al.* 2021). Due to their small body size, cryptic behaviour, low densities and small school sizes, these whales are difficult to observe at sea, and morphological similarities make field identification to species level problematic, although their narrow-band high frequency echolocation clicks make them detectable and identifiable (at least to the genus) using passive acoustic monitoring equipment. The majority of what is known about the distribution and ecology of Kogiid whales in the southern African subregion is derived mainly from stranding records (e.g. Ross 1979; Findlay *et al.* 1992; Plön 2004; Elwen *et al.* 2013, but see also Moura *et al.* 2016). *Kogia* species are most frequently occur in pelagic and shelf edge waters, are thus likely to occur in the survey area at low levels; seasonality is unknown. Dwarf sperm whales are associated with warmer tropical and warm-temperate waters, being recorded from both the Benguela and Agulhas ecosystem (Best 2007) in waters deeper than ~1 000 m.

During 2020 the incidence of kogiid strandings between Strandfontein on the West Coast and Groot Brak River on the South Coast (n=17), was considerably higher than the annual average during the previous 10 years (n=7). The dwarf sperm whale (*K. sima*) accounted for 60% of these strandings, of which most were recorded during autumn and winter. These seasonal stranding patterns are consistent with previously published accounts for the South African coast. In 2020, 40% of the total

BL28

strandings were recorded in winter and 15% during summer. The occurrence of strandings throughout the year may, however, indicate the presence of a resident population with a seasonal distribution off the South Coast in autumn and winter (Seakamela *et al.* 2020, 2021). The cause of the strandings is unknown.

Killer whales: Killer whales in South African waters were referred to a single morphotype, Type A, although recently a second 'flat-toothed' morphotype that seems to specialise in an elasmobranch diet has been identified but only 5 records are known all from strandings (Best *et al.* 2014). Killer whales (Figure 34) have a circum-global distribution being found in all oceans from the equator to the ice edge (Best 2007). Killer whales occur year-round in low densities off South Africa (Best *et al.* 2010, Elwen *et al.* in prep.), Namibia (Elwen & Leeney 2011) and in the Eastern Tropical Atlantic (Weir *et al.* 2010). Historically sightings were correlated with that of baleen whales, especially sei whales on their southward migration. In more recent years - their presence in coastal waters (e.g. False Bay) has been strongly linked to the presence and hunting of common dolphins (Best *et al.* 2010; Sea Search unpublished data). Further from shore, there have been regular reports of killer whales associated with long-line fishing vessels on the southern and eastern Agulhas Bank, and the Cape Canyon to the south-west of Cape Point. Killer whales are found in all depths from the coast to deep open ocean environments and may thus be encountered in the project area at low levels.

False killer whale: Although the false killer whale is globally recognized as one species, clear differences in morphological and genetic characteristics between different study sites show that there is substantial difference between populations and a revision of the species taxonomy may be needed (Best 2007). False killer whales are more likely to be confused with the smaller melon-headed or pygmy killer whales with which they share all-black colouring and a similar head-shape, than with killer whales. The species has a tropical to temperate distribution and most sightings off southern Africa have occurred in water deeper than 1 000 m, but with a few recorded close to shore (Findlay *et al.* 1992). They usually occur in groups ranging in size from 1 - 100 animals (Best 2007). The strong bonds and matrilineal social structure of this species makes it vulnerable to mass stranding (8 instances of 4 or more animals stranding together have occurred in the Western Cape, all between St Helena Bay and Cape Agulhas). There is no information on population numbers or conservation status and no evidence of seasonality in the region (Best 2007).

Pilot Whales: Long finned pilot whales display a preference for temperate waters and are usually associated with the continental shelf or deep water adjacent to it, but moving inshore to follow prey (primarily squid) (Mate *et al.* 2005; Findlay *et al.* 1992; Weir 2011; Seakamela *et al.* 2022). They are regularly seen associated with the shelf edge by MMOs, fisheries observers and researchers. The distinction between long-finned and short finned pilot whales is difficult to make at sea. As the latter are regarded as more tropical species confined to the southwest Indian Ocean (Best 2007), it is likely that the majority of pilot whales encountered in the project area will be long-finned. There are many confirmed sightings of pilot whales along the shelf edge of South Africa and Namibia including within the survey area since 2010 (de Rock *et al.* 2019; Sea Search unpublished data, SLR data). Observed group sizes range from 8-100 individuals (Seakamela *et al.* 2022). Pilot whales are commonly sighting by MMOs and detected by PAM during a seismic surveys. A recent tagging study showed long-finned pilot whale movements within latitudes of 33-36°S, along the shelf-edge from offshore of Cape Columbine to the Agulhas Bank, with concentrations in canyon areas, especially around the Cape Point Valley, and to a lesser degree around the Cape Canyon. It is postulated that the pilot whales target prey species in these productive areas (Seakamela *et al.* 2022).

Common dolphin: Two forms of common dolphins occur around southern Africa, a long-beaked and short-beaked form (Findlay *et al.* 1992; Best 2007), although they are currently considered part of a single global species (Cunha *et al.* 2015). The long-beaked common dolphin lives on the continental shelf of south Africa rarely being observed north of St Helena Bay on the west coast or in waters more 500 m deep (Best 2007), although more recent sightings, including those from MMOs, suggest sightings regularly out to 1 000 m or more (SLR data, Sea Search data). Group sizes of common dolphins can be large, averaging 267 (± SD 287) for the South Africa region (Findlay *et al.* 1992). Far less is known about the short-beaked form, which is challenging to differentiate at sea from the long-beaked form. Group sizes are also typically large. It is likely that common dolphins encountered in the Northern Cape or deeper than 2 000 m are of the short-beaked form.

Dusky dolphin: In water <500 m deep, dusky dolphins (Figure 35, right) are likely to be the most frequently encountered small cetacean as they are very "boat friendly" and often approach vessels to bowride. The species is resident year round throughout the Benguela ecosystem in waters from the coast to at least 500 m deep (Findlay *et al.* 1992). A recent abundance estimate from southern Namibia calculated roughly ~3 500 dolphins in the ~400 km long Namibian Islands Marine Protected area (Martin *et al.* 2020), at a density of 0.16 dolphins/km^2 and similar density is expected to occur off the South African coast where they are regularly encountered in near shore waters between Cape Town and Lamberts Bay (Elwen *et al.* 2010; NDP unpubl. data) with group sizes of up to 800 having been reported (Findlay *et al.* 1992). Dusky dolphins are resident year round in the Benguela.

Heaviside's dolphins: Heaviside's dolphins (Figure 35, left) are relatively abundant in the Benguela ecosystem region with 10 000 animals estimated to live in the 400 km of coast between Cape Town and Lambert's Bay (Elwen *et al.* 2009) and ~1 600 in the ~400 km long Namibian Islands Marine Protected Area (Martin *et al.* 2020). This species occupies waters from the coast to at least 200 m depth, (Elwen *et al.* 2006; Best 2007; Martin *et al.* 2020), and may show a diurnal onshore-offshore movement pattern (Elwen *et al.* 2010a, 2010b), as they feed offshore at night. Heaviside's dolphins are resident year round but will only occur well inshore of the Reconnaissance Permit Area.

Figure 35: The dusky dolphin *Lagenorhynchus obscurus* (left) and endemic Heaviside's Dolphin *Cephalorhynchus heavisidii* (right) (Photos: Simon Elwen, Sea Search Research and Conservation).

Bottlenose dolphin: Two species of bottlenose dolphins occur around southern Africa. The smaller Indo-Pacific bottlenose dolphin (*aduncus* form) occurs exclusively to the east of Cape Point in water usually less than 50 m deep and generally within 1 km of the shore (Ross 1984; Ross *et al.* 1987). The

larger common bottlenose dolphin (*truncatus* form) is widely distributed in tropical and temperate waters throughout the world, but frequently occur in small (10s to low 100s) isolated coastal populations. An offshore 'form' of common bottlenose dolphins occurs around the coast of southern Africa including Namibia and Angola (Best 2007) with sightings restricted to the continental shelf edge and deeper. Offshore bottlenose dolphins frequently form mixed species groups, often with pilot whales or Risso's dolphins. Encounters in the offshore waters of Reconnaissance Permit Area are likely to be low.

Risso's Dolphin: A medium sized dolphin with a distinctively high level of scarring and a proportionally large dorsal fin and blunt head. Risso's dolphins are distributed worldwide in tropical and temperate seas and show a general preference for shelf edge waters <1 500 m deep (Best 2007; Purdon *et al.* 2020a, 2020b). Many sightings in southern Africa have occurred around the Cape Peninsula and along the shelf edge of the Agulhas Bank. Presence within the inshore portions of the Reconnaissance Permit Area is possible (see Figure 28).

Other Delphinids: Several other species of dolphins that might occur in deeper waters at low levels include the pygmy killer whale, southern right whale dolphin, rough toothed dolphin, pantropical spotted dolphin and striped dolphin (Findlay *et al.* 1992; Best 2007). Nothing is known about the population size or density of these species in the project area but encounters are likely to be rare.

Beaked whales: These whales were never targeted commercially and their pelagic distribution makes them the most poorly studied group of cetaceans. They are all considered to be true deep water species usually being seen in waters in excess of 1 000 - 2 000 m deep (see various species accounts in Best 2007). With recorded dives of well over an hour and in excess of 2 km deep, beaked whales are amongst the most extreme divers of any air breathing animals (Tyack *et al.* 2011). All the beaked whales that may be encountered in the project area are pelagic species that tend to occur in small groups usually less than five, although larger aggregations of some species are known (MacLeod & D'Amico 2006; Best 2007). The long, deep dives of beaked whales make them difficult to detect visually, but PAM will increase the probability of detection as animals are frequently echo-locating when on foraging dives. Beaked whales seem to be particularly susceptible to man-made sounds and several strandings and deaths at sea, often *en masse*, have been recorded in association with mid-frequency naval sonar (Cox *et al.* 2006; MacLeod & D'Amico 2006) and a seismic survey for hydrocarbons also running a multi-beam echo-sounder and sub bottom profiler (Southall *et al.* 2008; Cox *et al.* 2006; DeRuiter *et al.* 2013). Although the exact reason that beaked whales seem particularly vulnerable to man-made noise is not yet fully understood, existing evidence suggests that animals change their dive behaviour in response to acoustic disturbance (Tyack *et al.* 2011), showing a fear-response and surfacing too quickly with insufficient time to release nitrogen resulting in a form on decompression sickness. Necropsy of stranded animals has revealed gas embolisms and haemorrhage in the brain, ears and acoustic fat - injuries consistent with decompression sickness (acoustically mediated bubble formation) (Fernandez *et al.* 2005). Beyond decompression sickness, the fear/flee response may be the first stage in a multi-stage process ultimately resulting in stranding (Southall *et al.* 2008; Jepson *et al.* 2013). Thus, although hard to detect and avoid - beaked whales are amongst the most sensitive marine mammals to noise exposure and all cautions must be taken to reduce impact. Presence in the project area may fluctuate seasonally, but insufficient data exist to define this clearly. Sightings of beaked whales in the project area are expected to be very low.

All whales and dolphins are given protection under the South African Law. The Marine Living Resources Act, 1998 (No. 18 of 1998) states that no whales or dolphins may be harassed, killed or

fished. No vessel or aircraft may, without a permit or exemption, approach closer than 300 m to any whale and a vessel should move to a minimum distance of 300 m from any whales if a whale surfaces closer than 300 m from a vessel or aircraft.

Seals

The Cape fur seal (*Arctocephalus pusillus pusillus*) (Figure 36) is the only species of seal resident along the west coast of Africa, occurring at numerous breeding and non-breeding sites on the mainland and on nearshore islands and reefs (see Figure 40). The South African population, which includes the West Coast colonies, was estimated at ca. 725 000 individuals in 2020. This is about 40% of the total southern African population, which has previously been estimated at up to 2 million (Seakamela *et al.* 2022). Vagrant records from four other species of seal more usually associated with the subantarctic environment have also been recorded: southern elephant seal (*Mirounga leonina*), subantarctic fur seal (*Arctocephalus tropicalis*), crabeater (*Lobodon carcinophagus*) and leopard seals (*Hydrurga leptonyx*) (David 1989).

Figure 36: Colony of Cape fur seals *Arctocephalus pusillus pusillus* (Photo: Dirk Heinrich).

There are a number of Cape fur seal colonies within the broader study area: at Buchu Twins near Alexander Bay, at Cliff Point (~17 km north of Port Nolloth), at Kleinzee (incorporating Robeiland), Strandfontein Point (south of Hondeklipbaai), Paternoster Rocks and Jacobs Reef at Cape Columbine, Vondeling Island, Robbesteen near Koeberg, Seal Island in False Bay and Geyser Rock at Dyer Island, Quoin Point and Seal Island in Mossel Bay. The colony at Kleinzee has the highest seal population and produces the highest seal pup numbers on the South African Coast (Wickens 1994). The colony at Buchu Twins and Cliff Point, formerly non-breeding colonies, have also attained breeding status (M. Meyer, SFRI, pers. comm.). Non-breeding colonies and haul-out sites occur occur at Doringbaai south of Cliff Point, Rooiklippies, Swartduin and Noup between Kleinzee and Hondeklipbaai, at Spoeg River and Langklip south of Hondeklip Bay, on Bird Island at Lambert's Bay, at Paternoster Point at Cape Columbine and Duikerklip in Hout Bay. These colonies all fall well inshore and to the east of the Reconnaissance Permit Area.

Seals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles offshore (Shaughnessy 1979), with bulls ranging further out to sea than females. Their

diet varies with season and availability and includes pelagic species such as horse mackerel, pilchard, and hake, as well as squid and cuttlefish. Benthic feeding to depths of nearly 200 m for periods of up to 2 minutes has, however, also been recorded (Kirkman et al. 2015). Seals are unlikely to be encountered in the offshore waters of the Reconnaissance Permit Area (Figure 37).

The timing of the annual breeding cycle is very regular, occurring between November and January. Breeding success is highly dependent on the local abundance of food, territorial bulls and lactating females being most vulnerable to local fluctuations as they feed in the vicinity of the colonies prior to and after the pupping season (Oosthuizen 1991).

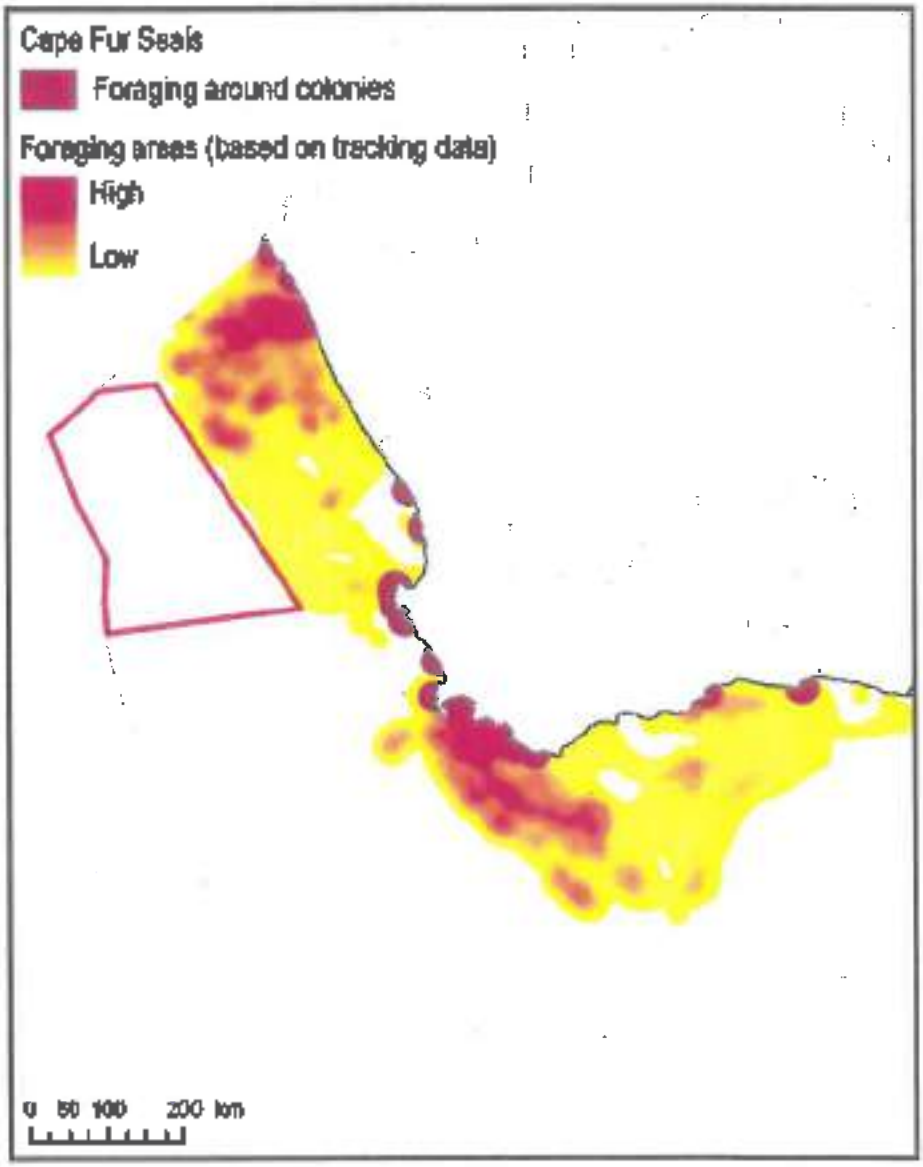

Figure 37: Reconnaissance Permit Area (red polygon) in relation to seal foraging areas on the West and South Coasts. Brown areas are generalised foraging areas around colonies, and areas in shades of red are foraging areas based on tracking data. Darker shades of red indicate areas of higher use.

Historically the Cape fur seal was heavily exploited for its luxurious pelt. Sealing restrictions were first introduced to southern Africa in 1893, and harvesting was controlled until 1990 when it was

finally prohibited. The protection of the species has resulted in the recovery of the populations, and numbers continue to increase. Consequently, their conservation status is not regarded as threatened. The Cape Fur Seal population in South Africa is regularly monitored by the Department of Fisheries, Forestry and Environment (DFFE) (e.g. Kirkman *et al.* 2013). The overall population is considered healthy and stable in size, although there has been a westward and northward shift in the distribution of the breeding population (Kirkman *et al.* 2013).

An unprecedented mortality event was recorded in South Africa between September and December 2021 at colonies around the West Coast Peninsula and north to Lambert's Bay and Elands Bay. Primarily pups and juveniles were affected. Post-mortem investigations revealed that seals died in a poor condition with reduced blubber reserves, and protein energy malnutrition was detected for aborted foetuses, for juveniles and subadults. Although no unusual environmental conditions were identified that may have triggered the die-off, or caused it indirectly (e.g. HABs), 2021 was a year of below average recruitment of anchovy and sardine, the main food source for seals. While a lack of food, as a result of possibly climate change and/or overfishing, has been predicted to be the cause of this mass mortality, the underlying causes of the mortality event remain uncertain (Seakamela *et al.* 2022).

3.4 Other Uses of the Area

3.4.1 Beneficial Uses

The proposed 3D survey area is located well offshore beyond the 1 000 m depth contour. Other users of the offshore areas include the commercial fishing industry (see CapMarine 2022 - Fisheries Specialist Study), with marine diamond mining concessions being located well inshore of the eastern portion of the Reconnaissance Permit Area (Figure 38). Recreational activities along the coastline north of St Helena Bay are limited to the area around Lambert's Bay, Hondeklip Bay and Port Nolloth.

On the Namaqualand coast marine diamond mining activity is restricted to nearshore, diver-assisted operations from small, converted fishing vessels working in the a-concessions, which extend to 1 000 m offshore of the high water mark. No deep-water diamond mining is currently underway in the South African offshore concession areas, although prospecting activities are ongoing. In Namibian waters, deep-water diamond mining by De Beers Marine Namibia is currently operational in the Atlantic 1 Mining Licence Area, immediately to the northeast of the Reconnaissance Permit Area.

These mining operations are typically conducted to depths of 150 m from fully self-contained mining vessels with on board processing facilities, using either large-diameter drill or seabed crawler technology. The vessels operate as semi-mobile mining platforms, anchored by a dynamic positioning system, commonly on a three to four anchor spread (Figure 39). Computer-controlled positioning winches enable the vessels to locate themselves precisely over a mining block of up to 400 m x 400 m. These mining vessels thus have limited manoeuvrability and other vessels should remain at a safe distance.

Other industrial uses of the marine environment include the intake of feed-water for mariculture, or diamond-gravel treatment, submarine telecommunications cables, ammunition dumps and hydrocarbon wellheads (Figure 38). None of these activities should in any way be affected by 3D seismic survey activities offshore.

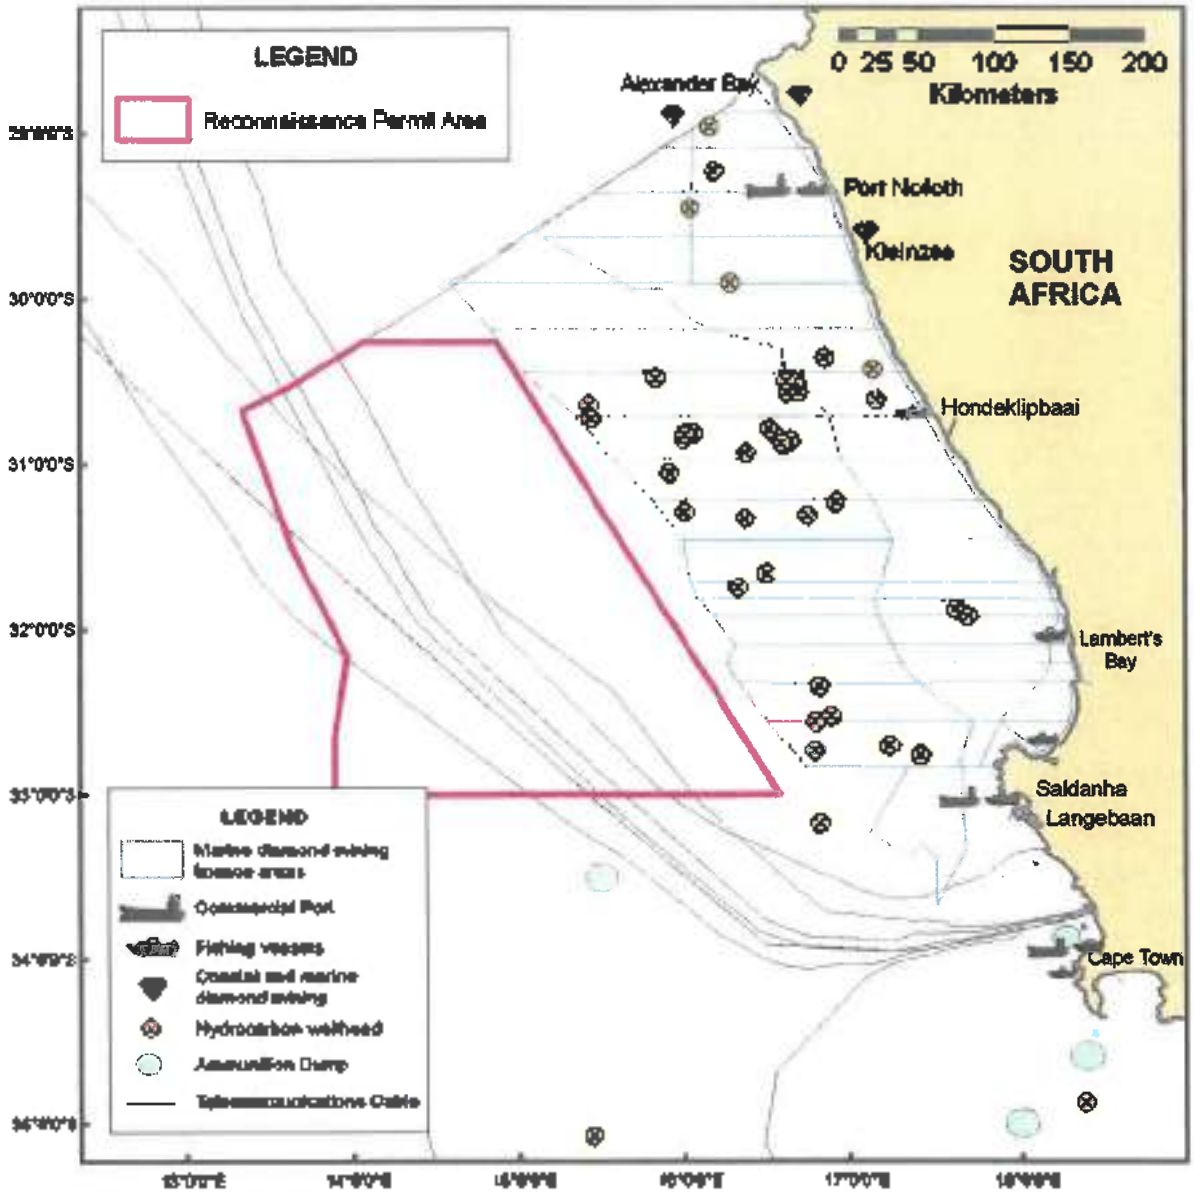

Figure 38: The Reconnaissance Permit Area (red polygon) in relation to project - environment interaction points on the West Coast, illustrating the location of marine diamond mining concessions and ports for commercial and fishing vessels. Existing hydrocarbon wellheads, telecommunications cables and ammunition dumps are also shown.

Figure 39: Typical crawler-vessel (left) and drillship (right) operating in the Atlantic 1 Mining Licence Area (Photos: De Beers Marine).

3.4.2 Conservation Areas and Marine Protected Areas

Numerous sanctuaries, marine protected areas (MPAs) exist offshore and along the coastline of the Western Cape, although none of them overlap with the Reconnaissance Permit Area. For the sake of completeness, these are described in more detail below.

Sanctuaries

Sanctuaries are considered a type of management area within South Africa's multi-purpose expanded MPA network in which access and/or resource use is prohibited. Sanctuaries in the vicinity of the project area in which restrictions apply are the McDougall's Bay, Stompneusbaai, Saldanha Bay, Table Bay and Hout Bay rock lobster sanctuaries, which are closed to commercial exploitation of rock lobsters. These sanctuaries were originally proclaimed early in the 20th century under the Sea Fisheries Act of 1988 as a management tool for the protection of the West Coast rock lobster (Mayfield *et al.* 2005). They lie well inshore or to the south of the Reconnaissance Permit Area.

Marine Protected Areas

'No-take' MPAs offering protection of the Namaqua biozones (sub-photic, deep-photic, shallow-photic, intertidal and supratidal zones) are absent northwards from Cape Columbine (Emanuel *et al.* 1992, Lombard *et al.* 2004). This resulted in substantial portions of the coastal and shelf-edge marine biodiversity in the area being assigned a threat status of 'Critically Endangered', 'Endangered' or 'Vulnerable' in the 2011 National Biodiversity Assessment (NBA) (Lombard *et al.* 2004; Sink *et al.* 2012). Using biodiversity data mapped for the 2004 and 2011 NBAs a systematic biodiversity plan was developed for the West Coast (Majiedt *et al.* 2013) with the objective of identifying both coastal and offshore priority areas for MPA expansion. Potentially vulnerable marine ecosystems (VMEs) that were explicitly considered during the planning included the shelf break, seamounts, submarine canyons, hard grounds, submarine banks, deep reefs and cold water coral reefs. To this end, nine focus areas were identified for protection on the West Coast between Cape Agulhas and the South African - Namibian border. These focus areas were carried forward during Operation Phakisa, which identified potential offshore MPAs. A network of 20 MPAs was gazetted on 23 May 2019, thereby increasing the ocean protection within the South African Exclusive Economic Zone (EEZ) to 5%. The approved MPAs within the broad project area are shown in Figure 40. There are six offshore Marine Protected Areas

(MPAs) that fall within the broader project area, namely the Orange Shelf Edge MPA, Child's Bank MPA, Benguela Muds MPA, Cape Canyon MPA, Robben Island MPA and the Southeast Atlantic Seamounts MPA. These are described briefly below.

The Orange Shelf Edge MPA covers depths of between 250 m and 1 500 m and is unique as it has to date never been trawled. Proclaimed in 2019, this MPA provides a glimpse into what a healthy seabed should look like, what animals live there and how the complex relationships between them support important commercial fish species such as hake, thereby contributing fundamentally towards sustainable fisheries development. This MPA also protects the pelagic habitats that are home to predators such as blue sharks, as well as surface waters where thousands of seabirds such as Atlantic yellow-nosed albatrosses feed. The MPA lies ~10 km to the north of the northern boundary of the Reconnaissance Permit Area.

The 1 335 km^2 Child's Bank MPA, located 27 km inshore of the Reconnaissance Permit Area at its closest point, supports seabed habitats inhabited by a diversity of starfish, brittle stars and basket stars, many of which feed in the currents passing the bank's steep walls. Although trawling has damaged coral in the area, some pristine coral gardens remain on the steepest slopes. The Child's Bank area was first proposed for protection in 2004 but was only proclaimed in 2019, after reducing its size to avoid petroleum wellheads and mining areas. The MPA provides critical protection to these deep sea habitats (180 - 450 m) as they allow for the recovery of important nursery areas for young fish.

The Benguela Muds MPA is the smallest of the South African offshore MPAs. At only 71 km^2 the muddy habitats located in this area are created by sediment washed down the Orange River and out to sea. These mud habitats are of limited extent and were considered 'critically endangered' on South Africa's deep continental margin of the west coast (Sink *et al.* 2014). The MPA represents the least trawled stretch of muddy seabed on the west coast. This MPA is located 28 km east of the southern portion of the Reconnaissance Permit Area.

The Cape Canyon is a deep and dramatic submarine canyon carved into the continental shelf and extending to a maximum depth of 3,600 m. The 580 km^2 MPA was proclaimed in 2019 and protects the upper part of the canyon where depths range from 180 to 500 m. Underwater footage has revealed a rich diversity of seafans, hermit crabs and mantis shrimps, with hake, monk and john dory resident on the soft canyon floor. Rocky areas in the west of the canyon support fragile rocky habitat, but the area also includes sandy and muddy habitats, which have been trawled in the past. Interaction of nutrient-rich bottom water with a complex seascape results in upwelling, which in turn provides productive surface waters in which seabirds, humpback whales and Cape fur seals feed. The MPA lies 78 km east of the southeastern corner of the Reconnaissance Permit Area.

The Namaqua Fossil Forest MPA, which lies ~173 km inshore of the Reconnaissance Permit Area, provides evidence of age-old temperate yellowwood forests from a hundred million years ago when the sea-level was more than 200 m below what it is today; trunks of fossilized yellowwood trees covered in delicate corals. These unique features stand out against surrounding mud, silt and gravel habitats. The fossilized trees are not known to be found anywhere else in our oceans and are valuable for research into past climates. In 2014 this area was recognised as globally important and declared as an Ecologically and Biologically Significant Area (EBSA). The 1 200 km^2 MPA protects the unique fossil forests and the surrounding seabed ecosystems and including a new species of sponge previously unknown to science.

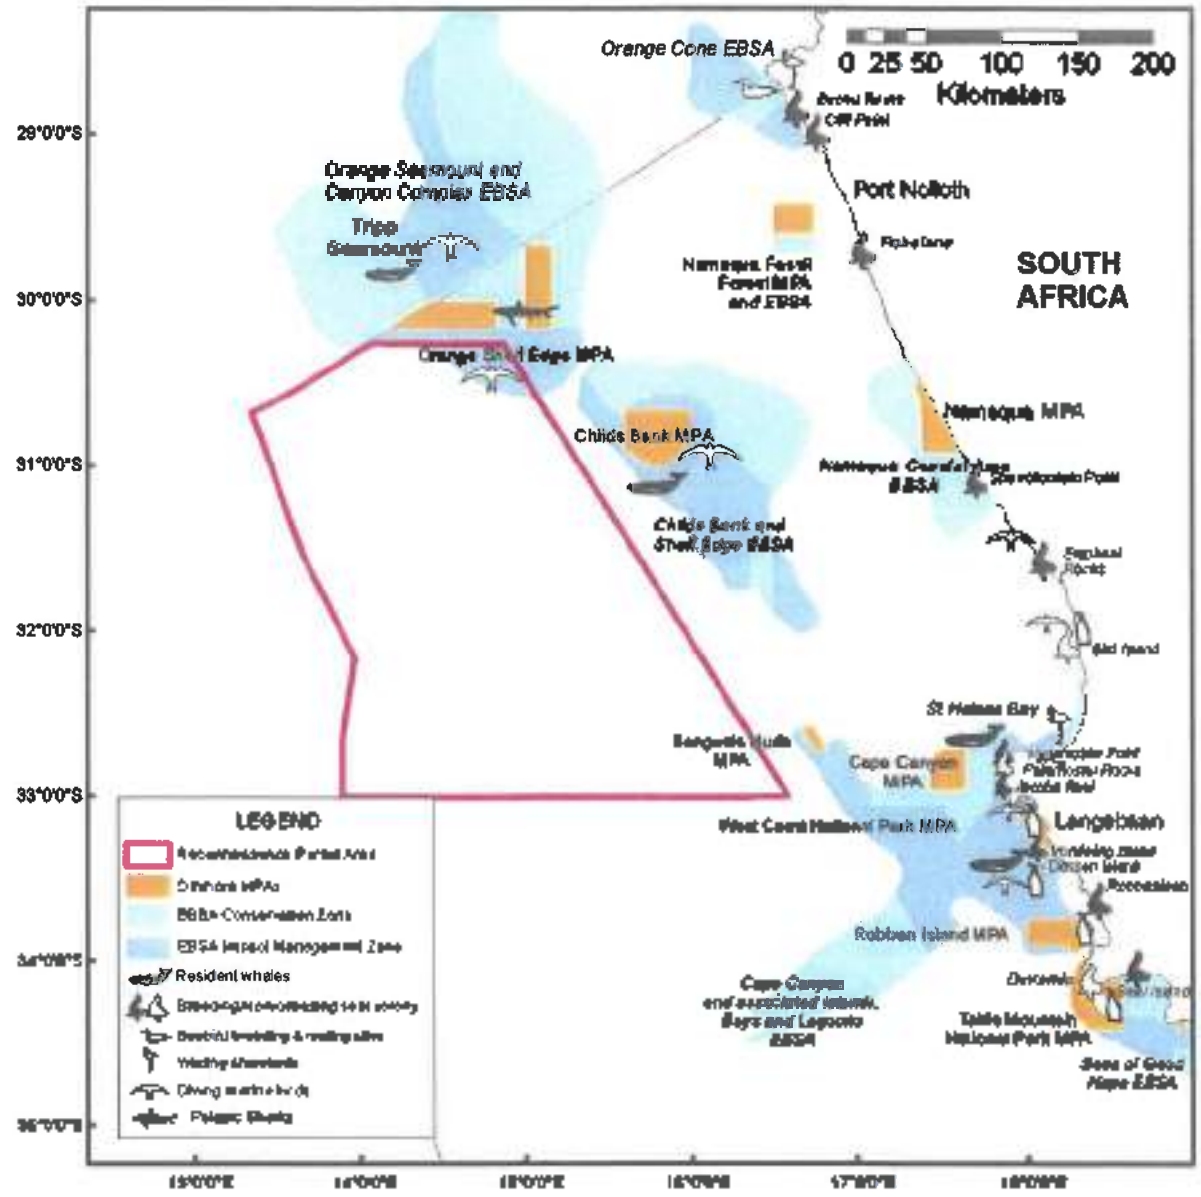

Figure 40: The Reconnaissance Permit Area (red polygon) in relation to project - environment interaction points on the West Coast, illustrating the location of seabird and seal colonies and resident whale populations, Marine Protected Areas (MPAs) and Ecologically and Biologically Significant Areas (EBSAs).

The Namaqua National Park MPA provides the first protection to habitats in the Namaqua bioregion, including several 'critically endangered' coastal ecosystem types. The area is a nursery area for Cape hakes, and the coastal areas support kelp forests and deep mussel beds, which serve as important habitats for the West Coast rock lobster. This 500 km² MPA was proclaimed in 2019, both to boost tourism to this remote area and to provide an important baseline from which to understand ecological changes (e.g. introduction of invasive alien marine species, climate change) and human impacts (harvesting, mining) along the West Coast. Protecting this stretch of coastline is part of South Africa's climate adaptation strategy.

The 612 km² Robben Island MPA was proclaimed in 2019 to protect the surrounding kelp forests - one of the few areas that still support viable stocks of abalone. The island harbours the 3rd largest penguin colony, with the breeding population peaking in 2004 at 8 524, but declining since. The island also holds the largest numbers of breeding Bank Cormorant in the Western Cape (120 pairs in 2000) and significant populations of Crowned Cormorant, African Black Oystercatcher (35 breeding pairs in 2000), Hartlaub's Gull and Swift Tern.

The Rocher Pan MPA, which stretches 500 m offshore of the high water mark of the adjacent Rocher Pan Nature Reserve, was declared in 1966. The MPA primarily protects a stretch of beach important as a breeding area to numerous waders.

The West Coast National Park, which was established in 1985 incorporates the Langebaan Lagoon and Sixteen Mile Beach MPAs, as well the islands Schaapen (29 ha), Marcus (17 ha), Malgas (18 ha) and Jutten (43 ha). Langebaan Lagoon was designated as a Ramsar site in April 1988 under the Convention on Wetlands of International Importance especially as Waterfowl Habitat. The lagoon is divided into three different utilization zones namely: wilderness, limited recreational and multi-purpose recreational areas. The wilderness zone has restricted access and includes the southern end of the lagoon and the inshore islands, which are the key refuge sites of the waders and breeding seabird populations respectively. The limited recreation zone includes the middle reaches of the lagoon, where activities such as sailing and canoeing are permitted. The mouth region is a multi-purpose recreation zone for power boats, yachts, water-skiers and fishermen. However, no collecting or removal of abalone and rock lobster is allowed. The length of the combined shorelines of Langebaan Lagoon MPA and Sixteen Mile Beach is 66 km. The uniqueness of Langebaan lies in its being a warm oligotrophic lagoon, along the cold, nutrient-rich and wave exposed West Coast.

Sensitive Areas

Despite the development of the offshore MPA network a number of 'Endangered' and 'Vulnerable' ecosystem types (i.e. Orange Cone Inner Shelf Mud Reef Mosaic, Orange Cone Muddy mid Shelf, Namaqua Muddy Sands, Southern Benguela Outer Shelf Mosaic, Southern Benguela Shelf Edge Mosaic and Southeast Atlantic Lower Slope) are currently 'not well protected' and further effort is needed to improve protection of these threatened ecosystem types (Sink *et al.* 2019) (Figure 41). Ideally, all highly threatened ('Critically Endangered' and 'Endangered') ecosystem types should be well protected. Currently, however, most of the Southern Benguela Sandy Shelf Edge and Southeast Atlantic Upper- and Mid-Slope are poorly protected receiving only 0.2-10% protection, whereas the Southeast Atlantic Lower Slope receives no protection at all (Sink *et al.* 2019). Expanding the size of the Orange Shelf Edge MPA to form a single MPA along the South African Border could improve protection of these threatened habitats. Most of the ecosystem types in the proposed 3D survey area are either poorly protected or not protected.

Ecologically or Biologically Significant Areas

As part of a regional Marine Spatial Management and Governance Programme (MARISMA 2014-2020) the Benguela Current Commission (BCC) and its member states have identified a number of Ecologically or Biologically Significant Areas (EBSAs) both spanning the border between Namibia and South Africa and along the South African West, South and East Coasts (see Figure 40), with the intention of implementing improved conservation and protection measures within these sites. South Africa currently has 11 EBSAs solely within its national jurisdiction with a further four having recently been proposed. It also shares five trans-boundary EBSAs with Namibia (3) and Mozambique (2). The principal objective of these EBSAs is identification of features of higher ecological value that may

8425

require enhanced conservation and management measures. They currently carry no legal status. The impact management and conservation zones within the EBSAs are under review and currently constitute a subset of the biodiversity priority areas map (see next section); EBSA conservation zones equate to Critical Biodiversity Areas (CBAs), whereas impact management zones equate to Ecological Support Area (ESAs). The relevant sea-use guidelines accompanying the CBA areas would apply.

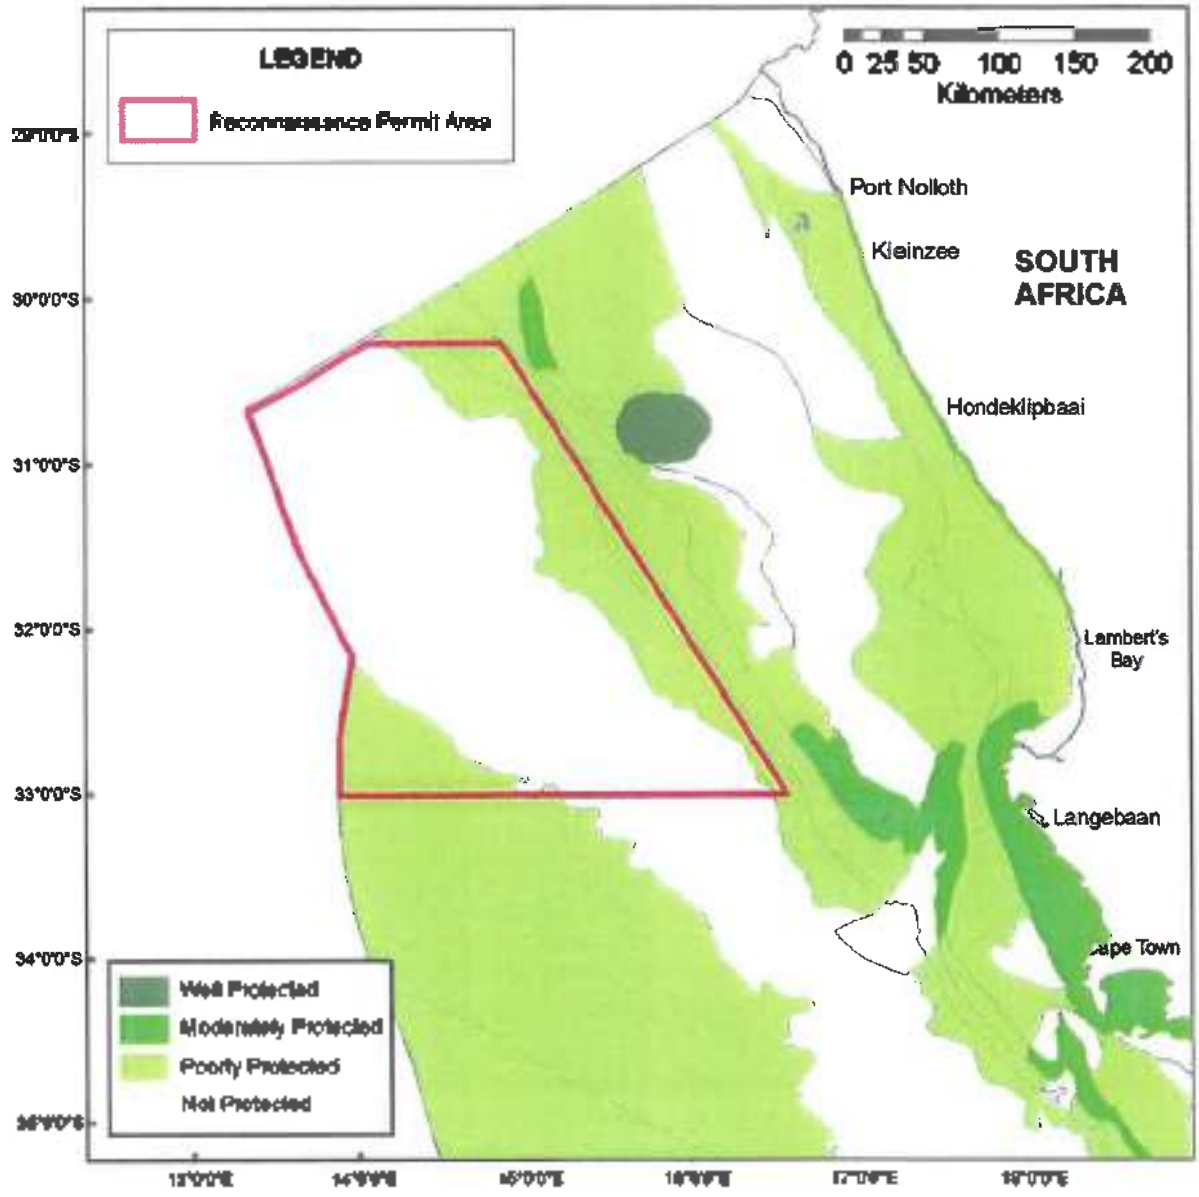

Figure 41: The Reconnaissance Permit Area (red polygon) in relation to protection levels of 150 marine ecosystem types as assessed by Sink *et al.* (2019).

The following summaries of the EBSAs in the Reconnaissance Permit area are adapted from http://cmr.mandela.ac.za/EBSA-Portal/Namibia/.

The Orange Seamount and Canyon Complex, occurs at the western continental margin of southern Africa, spanning the border between South Africa and Namibia. On the Namibian side, it includes

Tripp Seamount and a shelf-indenting canyon. The EBSA comprises shelf and shelf-edge habitat with hard and unconsolidated substrates, including at least eleven offshore benthic habitat types of which four habitat types are 'Threatened', one is 'Critically endangered' and one 'Endangered'. The Orange Shelf Edge EBSA is one of few places where these threatened habitat types are in relatively natural/pristine condition. The local habitat heterogeneity is also thought to contribute to the Orange Shelf Edge being a persistent hotspot of species richness for demersal fish species. Although focussed primarily on the conservation of benthic biodiversity and threatened benthic habitats, the EBSA also considers the pelagic habitat, which is characterized by medium productivity, cold to moderate Atlantic temperatures (SST mean = 18.3°C) and moderate chlorophyll levels related to the eastern limit of the Benguela upwelling on the outer shelf. There is an slight overlap of the Reconnaissance Permit Area with this EBSA.

The Orange Cone transboundary EBSA lies well inshore of the Reconnaissance Permit Area and spans the mouth of the Orange River. The estuary is biodiversity-rich but modified, and the coastal area includes many 'Critically endangered', 'Endangered' and 'Vulnerable' habitat types (with the area being particularly important for the 'Critically Endangered' Namaqua Sandy Inshore, Namaqua Inshore Reef and Hard Grounds and Namaqua Intermediate and Reflective Sandy Beach habitat types). The marine environment experiences slow, but variable currents and weaker winds, making it potentially favourable for reproduction of pelagic species. An ecological dependence for of river outflow for fish recruitment on the inshore Orange Cone is also likely. The Orange River Mouth is a transboundary Ramsar site and falls within the Tsau//Khaeb (Sperrgebiet) National Park. It is also under consideration as a protected area by South Africa, and is an Important Bird and Biodiversity Area.

The Namaqua Fossil Forest EBSA, which lies inshore of the Reconnaissance Permit Area, is a small seabed outcrop composed of fossilized yellowwood trees at 136-140 m depth, approximately 30 km offshore on the west coast of South Africa. A portion of the EBSA comprised the Namaqua Fossil Forest MPA. The fossilized tree trunks form outcrops of laterally extensive slabs of rock have been colonized by fragile, habitat-forming scleractinian corals and a newly described habitat-forming sponge species. The EBSA thus encompasses a unique feature with substantial structural complexity that is highly vulnerable to benthic impacts.

The Childs Bank and Shelf Edge EBSA, which lies ~ 17 km east of the Reconnaissance Permit Area at its closest point, is a unique submarine bank feature rising from 400 m to ~180 m on the western continental margin on South Africa. This area includes five benthic habitat types, including the bank itself, the outer shelf and the shelf edge, supporting hard and unconsolidated habitat types. Childs Bank and associated habitats are known to support structurally complex cold-water corals, hydrocorals, gorgonians and glass sponges; species that are particularly fragile, sensitive and vulnerable to disturbance, and recover slowly.

The Namaqua Coastal Area EBSA, which lies well inshore of the Reconnaissance Permit Area and encompasses the Namaqua Coastal Area MPA, is characterized by high productivity and community biomass along its shores. The area is important for several threatened ecosystem types represented there, including two 'Endangered' and four 'Vulnerable' ecosystem types, and is important for conservation of estuarine areas and coastal fish species.

The Cape Canyon and Associated Islands EBSA lies ~ 20 km inshore of the southern portion of the Reconnaissance Permit Area at its closest point. The EBSA includes the Benguela Muds MPA and the Cape Canyon, which is thought to hosts fragile habitat-forming species. The area is considered important for pelagic fish, foraging marine mammals and several threatened seabird species and

serves to protect nine 'Endangered' and 12 'Vulnerable' ecosystem types, and two that are 'Near Threatened'. There are several small coastal MPAs within the EBSA.

The proposed **Seas of Good Hope EBSA** is located at the coastal tip of Africa, wrapping around Cape Point and Cape Agulhas. It extends from the coast to the inner shelf, and includes key islands (Seal Island, Dyer Island And Geyser Rocks), two major bays (False Bay and Walker Bay), and is of key importance for threatened species and habitats. The threatened habitats include coastal, inshore and inner shelf ecosystem types. The important life-history stages supported by the area are breeding and/or foraging grounds for a myriad of top predators, including sharks, whales, and seabirds, some of which are threatened species. This EBSA is also the place where the Benguela and Agulhas Currents meet.

The **Benguela Upwelling System** is a transboundary EBSA is globally unique as the only cold-water upwelling system to be bounded in the north and south by warm-water current systems, and is characterized by very high primary production (>1 000 mg $C.m^{-2}.day^{-1}$). It includes important spawning and nursery areas for fish as well as foraging areas for threatened vertebrates, such as sea- and shorebirds, turtles, sharks, and marine mammals. Another key characteristic feature is the diatomaceous mud-belt in the Northern Benguela, which supports regionally unique low-oxygen benthic communities that depend on sulphide oxidising bacteria.

Biodiversity Priority Areas

The National Coastal and Marine Spatial Biodiversity Plan[3] comprises a map of Critical Biodiversity Areas (CBAs), Ecological Support Area (ESAs) and accompanying sea-use guidelines. The CBA Map presents a spatial plan for the marine environment, designed to inform planning and decision-making in support of sustainable development. The sea-use guidelines enhance the use of the CBA Map in a range of planning and decision-making processes by indicating the compatibility of various activities with the different biodiversity priority areas so that the broad management objective of each can be maintained. The intention is that the CBA Map (CBAs and ESAs) and sea-use guidelines inform the MSP Conservation Zones and management regulations, respectively.

The Reconnaissance Permit Area overlaps with areas mapped as Critical Biodiversity Area 1 (CBA 1): Natural and Critical Biodiversity Area 2: (CBA 2) Natural. Approximately 32.25 % of the proposed 3D acquisition area is covered by CBA 1 and CBA 2 Natural, 0.22% by CBA 1 and CBA 2 Restore, and 1.75% by ESA (see Figure 42). CBA 1 indicates irreplaceable or near-irreplaceable sites that are required to meet biodiversity targets with limited, if any, option to meet targets elsewhere, whereas CBA 2 are "best design sites" and there often alternative areas where feature targets can be met; however, these will be of higher cost to other sectors and / or will be larger areas.

[3] The latest version of National Coastal and Marine Spatial Biodiversity Plan (v1.2 was released in April 2022) (Harris *et al.* 2022). The Plan is intended to be used by managers and decision-makers in those national government departments whose activities occur in the coastal and marine space, e.g., environment, fishing, transport (shipping), petroleum, mining, and others. It is relevant for the Marine Spatial Planning Working Group where many of these departments are participating in developing South Africa's emerging marine spatial plans. It is also intended for use by relevant managers and decision-makers in the coastal provinces and coastal municipalities, EIA practitioners, organisations working in the coast and ocean, civil society, and the private sector.

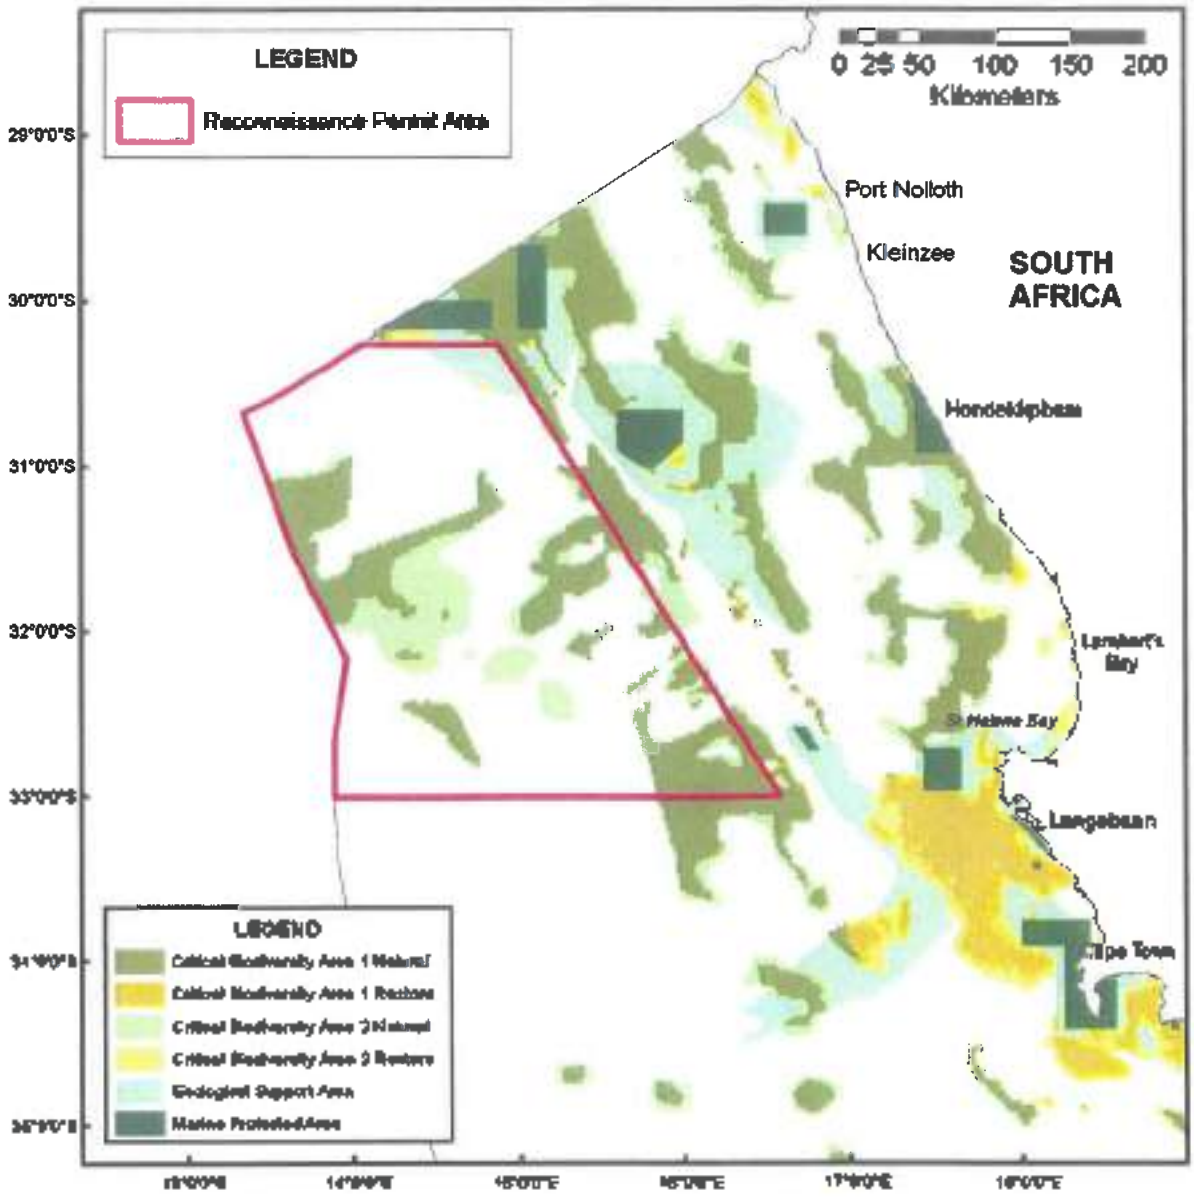

Figure 42: The Reconnaissance Permit Area (red polygon) in relation to Critical Biodiversity Areas (CBAs) and Ecological Support Areas (ESAs) (Version 1.2 April 2022).

Regardless of how CBAs are split, CBAs are generally areas of low use and with low levels of human impact on the marine environment, but can also include some moderately to heavily used areas with higher levels of human impact. Given that some CBAs are not in natural or near-natural ecological condition, but still have very high biodiversity importance and are needed to meet biodiversity feature targets, CBA 1 and CBA 2 were split into two types based on their ecological condition. CBA Natural sites have natural / near-natural ecological condition, with the management objective of maintaining the sites in that natural / near natural state; and CBA Restore sites have moderately modified or poorer ecological condition, with the management objective to improve ecological condition and, in the long-term, restore these sites to a natural/near-natural state, or as close to that state as possible. ESAs include all portions of EBSAs that are not already within MPAs or CBAs, and a 5-km

buffer area around all MPAs (where these areas are not already CBAs or ESAs), with the exception of the eastern edge of Robben Island MPA in Table Bay where a 1.5-km buffer area was applied (Harris *et al.* 2022).

Activities within these management zones are classified into those that are "compatible", those that are "not compatible", and those that have "restricted compatibility". Non-invasive (e.g. seismic surveys) and invasive (e.g. exploration wells) exploration activities are classified as having "restricted compatibility". Activities with restricted compatibility require a detailed assessment to determine whether the recommendation is that they should be permitted (general), permitted subject to additional regulations (consent), or prohibited, depending on a variety of factors. Petroleum production is, however, classified as "not compatible" in CBAs, but may be compatible, subject to certain conditions, in ESAs (Harris *et.al.* 2022).

Important Bird Areas (IBAs)

There are numerous coastal Important Bird Areas (IBAs) in the general project area (Table 9) (www.http://datazone.birdlife.org/). These are all located well inshore of the Reconnaissance Permit area and should in no way be directly affected by the proposed seismic surveys.

Table 9: List of Important Bird Areas (IBAs) and their criteria listings. RAMSAR sites are shaded.

Site Name	IBA Criteria
Orange River Mouth Wetlands (ZA023)	A1, A3, A4i, A4iii
Olifants River Estuary (ZA078)	A3, A4i
Verlorenvlei Estuary (ZA082)	A4i
Berg River Estuary (ZA083)	A4i
West Coast National Park and Saldanha Bay Islands (ZA 084) (incorporating Langebaan RAMSAR site)	A1, A4i, A4ii, A4iii
Dassen Island (ZA088)	A1, A4i, A4ii, A4iii
Robben Island (ZA089)	A1, A4i, A4ii, A4iii
Rietvlei Wetland: Table Bay Nature Reserve (ZA090)	A1, A4i
Boulders Beach (ZA096)	A1
False Bay Nature Reserve (ZA095)	A1, A4i, A4iii

A1. Globally threatened species
A2. Restricted-range species
A3. Biome-restricted species
A4. Congregations
i. applies to 'waterbird' species
ii. This includes those seabird species not covered under i.
iii. modelled on criterion 5 of the Ramsar Convention for identifying wetlands of international importance. The use of this criterion is discouraged where quantitative data are good enough to permit the application of A4i and A4ii.

The Orange River Mouth wetland located ~235 km to the northeast of the Reconnaissance Permit Area provides an important habitat for large numbers of a great diversity of wetland birds and is listed as a Global IBA (www. http://datazone.birdlife.org/). The area was designated a Ramsar site in June 1991, and processes are underway to declare a jointly-managed transboundary Ramsar reserve.

Various marine IBAs have also been proposed in South African and Namibian territorial waters, with a candidate trans-boundary marine IBA suggested off the Orange River mouth and a further candidate marine IBA suggested in international waters west of the Cape Peninsula (Figure 43). There is no overlap of the Reconnaissance Permit Area with any of these Marine IBAs.

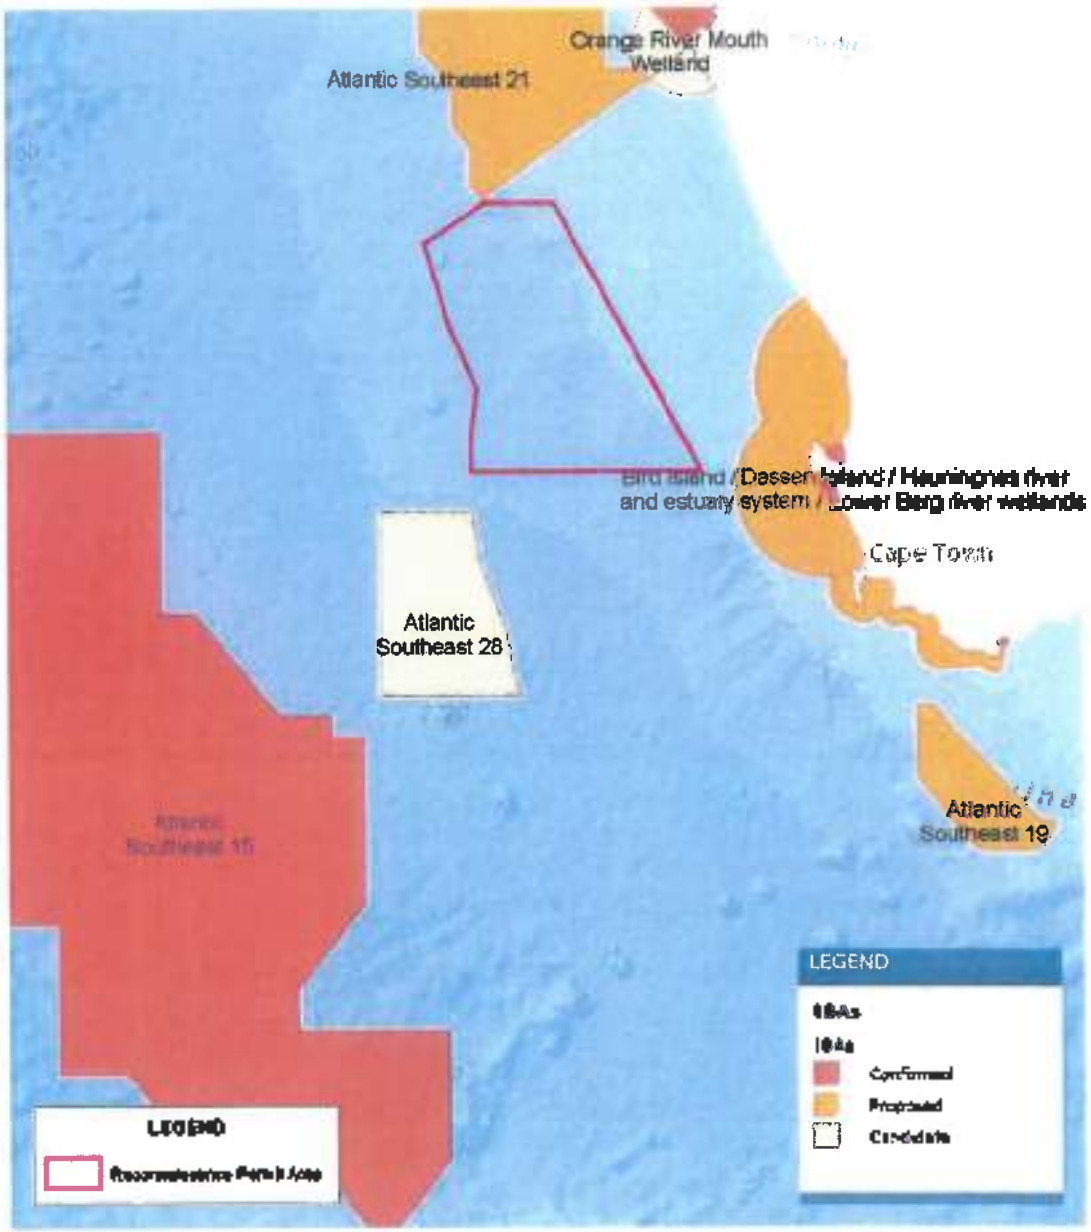

Figure 43: The Reconnaissance Permit Area (red polygon) in relation to coastal and marine IBAs in Namibia (Source: https://maps.birdlife.org/marineIBAs).

Important Marine Mammal Areas (IMMAs)

Important Marine Mammal Areas (IMMAs) were introduced in 2016 by the IUCN Marine Mammal Protected Areas Task Force to support marine mammal and marine biodiversity conservation. Complementing other marine spatial assessment tools, including the EBSAs and Key Biodiversity Areas (KBAs), IMMAs are identified on the basis of four main scientific criteria, namely species or population vulnerability, distribution and abundance, key life cycle activities and special attributes. Designed to capture critical aspects of marine mammal biology, ecology and population structure, they are devised through a biocentric expert process that is independent of any political and socio-economic pressure or concern. IMMAs are not prescriptive but comprise an advisory, expert-based classification of areas that merit monitoring and place-based protection for marine mammals and broader biodiversity.

Modelled on the BirdLife International process for determining IBAs, IMMAs are assessed against a number of criteria and sub-criteria, which are designed to capture critical aspects of marine mammal biology, ecology and population structure. These criteria are:

Criterion A - Species or Population Vulnerability

Areas containing habitat important for the survival and recovery of threatened and declining species.

Criterion B - Distribution and Abundance

Sub-criterion B1 - Small and Resident Populations: Areas supporting at least one resident population, containing an important proportion of that species or population that are occupied consistently.
Sub-criterion B2 - Aggregations: Areas with underlying qualities that support important concentrations of a species or population.

Criterion C - Key Life Cycle Activities

Sub-criterion C1 - Reproductive Areas: Areas that are important for a species or population to mate, give birth, and/or care for young until weaning.
Sub-criterion C2 - Feeding Areas: Areas and conditions that provide an important nutritional base on which a species or population depends.
Sub-criterion C3 - Migration Routes: Areas used for important migration or other movements, often connecting distinct life-cycle areas or the different parts of the year-round range of a non-migratory population.

Criterion D - Special Attributes

Sub-criterion D1 - Distinctiveness: Areas which sustain populations with important genetic, behavioural or ecologically distinctive characteristics.
Sub-criterion D2 - Diversity: Areas containing habitat that supports an important diversity of marine mammal species

Although much of the West Coast of South Africa has not yet been assessed with respect to its relevance as an IMMA, the coastline from the Olifants River mouth on the West Coast to the Mozambiquan border overlaps with three declared IMMAs (Figure 44) namely the

- Southern Coastal and Shelf Waters of South Africa IMMA (166 700 km^2),
- Cape Coastal Waters IMMA (6 359 km^2), and

8225

- South East African Coastal Migration Corridor IMMA (47 060 km²).

These are described briefly below based on information provided in IUCN-Marine Mammal Protected Areas Task Force (2021) (www.marinemammalhabitat.org).

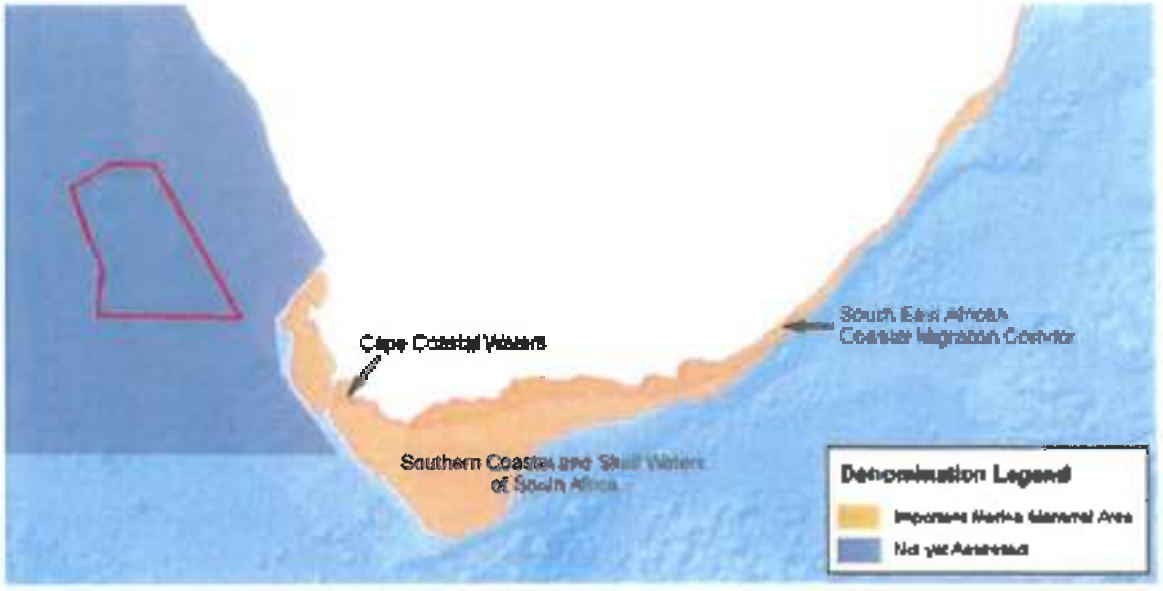

Figure 44: Reconnaissance Permit Area (red polygon) in relation to coastal and marine IMMAs (Source: www.marinemammalhabitat. org/imma-eatlas/).

The 166 700 km² Southern Coastal and Shelf Waters of South Africa IMMA extends from the Olifants River mouth to the mouth of the Cintsa River on the Wild Coast. Qualifying species are the Indian Ocean Humpback dolphin (Criterion A, B1), Bryde's whale (Criterion C2), Indo-Pacific bottlenose dolphin (Criterion B1, C3, D1), Common dolphin (Criterion C2) and Cape fur seal (criterion C2). The IMMA covers the area supporting the important 'sardine run' and the marine predators that follow and feed on the migrating schools (Criterion C2) as well as containing habitat that supports an important diversity of marine mammal species (Criterion D2) including the Indian Ocean humpback dolphin, the inshore form of Bryde's whale, Indo-Pacific bottlenose dolphin, common dolphin, Cape fur seal, humpback whales, killer whales and southern right whales.

The Cape Coastal Waters IMMA extends from Cape Point to Woody Cape at Algoa Bay and extends over some 6 359 km². It serves as one of the world's three most important calving and nursery grounds for southern right whales, which occur in the extreme nearshore waters (within 3 km of the coast) from Cape Agulhas to St. Sebastian Bay between June and November (Criterion B2, C1). Highest densities of cow-calf pairs occur between Cape Agulhas and the Duiwenhoks River mouth (Struisbaai, De Hoop, St Sebastian Bay), while unaccompanied adult densities peak in Walker Bay and False Bay. The IMMA also contains habitat that supports an important diversity of marine mammal species including the Indian Ocean humpback dolphin and Indo-Pacific bottlenose dolphin.

The South East African Coastal Migration Corridor IMMA extends some 47 060 km² from Cape Agulhas to the Mozambiquan border and serves as the primary migration route for C1 substock of Southern Hemisphere humpback whales (Criterion C3). On their northward migration between June and August, they are driven closer to shore due to the orientation of the coast with the Agulhas Current, whereas

during the southward migration from September to November, they remain further offshore (but generally within 15 km of the coast) utilising the southward flowing Agulhas Current as far west as Knysna. The IMMA also contains habitat that supports an important diversity of marine mammal species including the Indian Ocean humpback dolphin, Common dolphin, Indo-Pacific bottlenose dolphin, Spinner dolphin, Southern Right whale, and killer whale.

There is no overlap of the Reconnaissance Permit Area with these IMMAs as it falls within the area along the West Coast of South Africa that has not yet been assessed.

4. ASSESSMENT OF IMPACTS

For this project, the identification and assessment of impacts relating specifically to the marine ecology cover the four main activity phases (see Table 10 for an outline of the activities in these phases) of the proposed seismic acquisition project, namely:

- Mobilisation Phase
- Operational Phase
- Demobilisation Phase
- Unplanned Activities

4.1 Identification of Impacts

Interaction of these activities with the receiving environment gives rise to a number of environmental aspects, which in turn may result in a single or a number of impacts. The identified aspects and their potential impacts are summarised below, providing also the project phases during which the aspects would occur:

- Increase in underwater and atmospheric noise levels by the seismic vessel, during seismic acquisition, and by support vessels and helicopters
  - Disturbance / behavioural changes of coastal and marine fauna
  - Avoidance of key feeding areas (e.g. Child's Bank, Tripp Seamount and Southeast Atlantic Seamounts)
  - Effects on key breeding areas (e.g. coastal birds and cetaceans)
  - Abandonment of nests (birds) and young (birds and seals)
- Introduction of invasive alien species in the ballast water of the seismic vessel
  - Threats to West Coast ecosystem biodiversity
- Discharge of waste to sea (e.g. deck and machinery space drainage, sewage and galley wastes) from seismic and vessels, and local reduction in water quality
  - Reduced physiological functioning of marine organisms due to the biochemical effects on the water column
  - Increased food source for marine fauna
  - Fish aggregation and increased predator-prey interactions
- Increase in ambient lighting from seismic vessel and support vessels
  - Disorientation and mortality of marine birds
  - Physiological and behavioural effects on marine fauna
  - Fish aggregation and increased predator-prey interactions
- Localised reduction in water quality due to accidental release of fuel into the sea during bunkering and discharge of hydraulic fluid due to pipe rupture
  - Toxic effects on marine biota and reduced faunal health
- Uncontrolled release of oil/gas from the vessels due to vessel accident/collision
  - Toxic effects on marine biota and reduced faunal health
  - Pollution and smothering of coastal habitats
- Accidental loss of equipment
  - Disturbance and damage to seabed habitats
  - Entanglement of marine fauna

5228

4.2 Application of the Mitigation Hierarchy

A key component of this EMP process is to explore practical ways of avoiding and where not possible to reducing potentially significant impacts of the proposed seismic acquisition activities. The mitigation measures put forward are aimed at preventing, minimising or managing significant negative impacts to as low as reasonably practicable (ALARP). The mitigation measures are established through the consideration of legal requirements, project standards, best practice industry standards and specialist inputs.

The mitigation hierarchy, as specified in International Finance Corporation (IFC) Performance Standard 1, is based on a hierarchy of decisions and measures aimed at ensuring that wherever possible potential impacts are mitigated at source rather than mitigated through restoration after the impact has occurred. Any remaining significant residual impacts are then highlighted and additional actions are proposed. With few exceptions, however, identified impacts were of low to negligible significance with very low or zero potential for further mitigation. In such cases the appropriate project Standards will be used and additional best management practices are proposed.

4.3 Acoustic Impacts of Seismic Surveys on Marine Fauna

The ocean is a naturally noisy place and marine animals are continually subjected to both physically produced sounds from sources such as wind, rainfall, breaking waves and natural seismic noise, or biologically produced sounds generated during reproductive displays, territorial defence, feeding, or in echolocation (see references in McCauley 1994; Duarte *et al.* 2021).

Acoustic cues are thought to be important to many marine animals in the perception of their environment as well as for navigation purposes, predator avoidance, and in mediating social and reproductive behaviour. Anthropogenic sound sources in the ocean can thus be expected to interfere directly or indirectly with such activities thereby affecting the physiology and behaviour of marine organisms (NRC 2003). A comparison of the various noise sources in the ocean is shown in Figure 45.

Of all human-generated sound sources, the most persistent in the ocean is the noise of shipping (Erbe *et al.* 2018, 2019). Depending on size and speed, the sound levels radiating from vessels range from 160 to 220 dB re 1 µPa at 1 m (McCauley 1994; NRC 2003). Especially at low frequencies between 5 to 100 Hz, vessel traffic is a major contributor to noise in the world's oceans, and under the right conditions, these sounds can propagate hundreds of kilometres thereby affecting very large geographic areas (Coley 1994, 1995; NRC 2003; Pidcock *et al.* 2003; Duarte *et al.* 2021).

As the Reconnaissance Permit Area is located within the main offshore shipping routes that pass around southern Africa (Figure 46), the shipping noise component of the ambient noise environment is expected to be significant within and around the proposed 3D acquisition area (OceanMind Limited 2020). For the duration of the survey an exclusion zone would be established around the survey vessel. Given the significant local shipping traffic and relatively strong metocean conditions specific to the area, ambient noise levels are expected to be 90-130 dB re 1 µPa for the frequency range 10 Hz - 10 kHz (SLR Consulting Australia 2020, 2021).

Table 10: Aspects and impacts register relevant to marine fauna

Activity Phase		Activity	Aspect	Potential Impact
Seismic Surveying	Mobilisation Phase	Transit of survey vessels to survey area	Underwater noise levels	Disturbance to marine fauna
			Routine discharge to sea (e.g. deck and machinery space drainage, sewage and galley wastes) and local reduction in water quality	Physiological effect on marine fauna
				Increased food source for marine fauna
				Increased predator - prey interactions
			Vessel Lighting	Disorientation and mortality of marine birds
				Increased predator - prey interactions
			Discharge of ballast water and equipment fouling	Loss of biodiversity due to the introduction of invasive alien species
	Operation Phase	Operation of survey vessels	Increase in underwater noise levels	Disturbance to marine fauna
			Routine discharge of waste to sea (e.g. deck and machinery space drainage, sewage and galley wastes) and local reduction in water quality	Physiological effect on marine fauna
				Increased food source for marine fauna
				Fish aggregation and increased predator - prey interactions
			Increase in ambient lighting	Disorientation and mortality of marine birds
				Increased predator - prey interactions
		Seismic acquisition	Increase in underwater noise levels	Disturbance / behavioural changes to marine fauna
				Physiological effect on marine fauna
				Fish avoidance of key feeding areas
				Reduced fish catch and increased fishing effort
		Operation of helicopters	Increase in noise levels	Avoidance of key breeding areas (e.g. coastal birds and cetaceans)
				Abandonment of nests (birds) and young (birds and seals)
	Demobilisation Phase	Survey vessels leave survey area and transit to port or next destination	Increase in underwater noise levels during transit	Disturbance to marine fauna
			Routine discharge to sea (e.g. deck and machinery space drainage, sewage and galley wastes) and local reduction in water quality during transit	Physiological effect on marine fauna
				Increased food source for marine fauna
				Increased predator - prey interactions
			Increase in noise levels	Avoidance of key breeding areas (e.g. coastal birds and cetaceans)
				Abandonment of nests (birds) and young (birds and seals)
	Unplanned Activities	Collision with survey vessels and equipment	Collison and entanglement with marine fauna	Physiological effect on marine fauna
		Dropped objects / Lost equipment	Increased hard substrate on seafloor	Physical damage to and mortality of benthic species / habitats
				Obstruction to or damage of fishing gear
		Hydrocarbon spills	Release of fuel into sea during bunkering and localised reduction in water quality	Effect on faunal health (e.g. respiratory damage) or mortality (e.g. suffocation and poisoning)

975

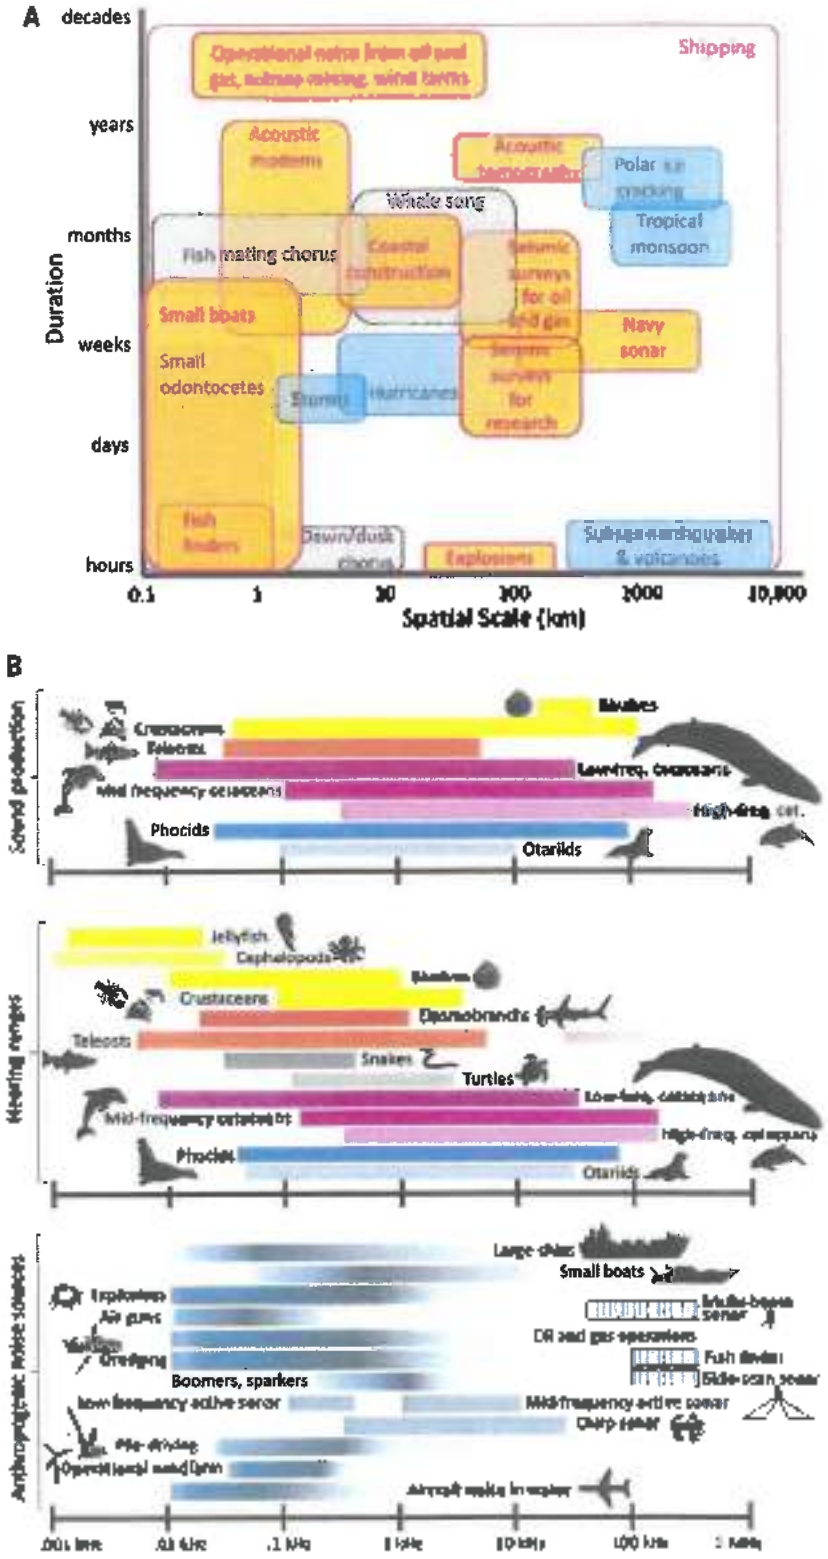

Figure 45: Sources and animal receivers of sound in the ocean. A) Spatial extent and duration of selected sound producing events, and B) Approximate sound production and hearing ranges of marine taxa and frequency ranges of selected anthropogenic sound sources. (Source: Duarte *et al.* 2021).

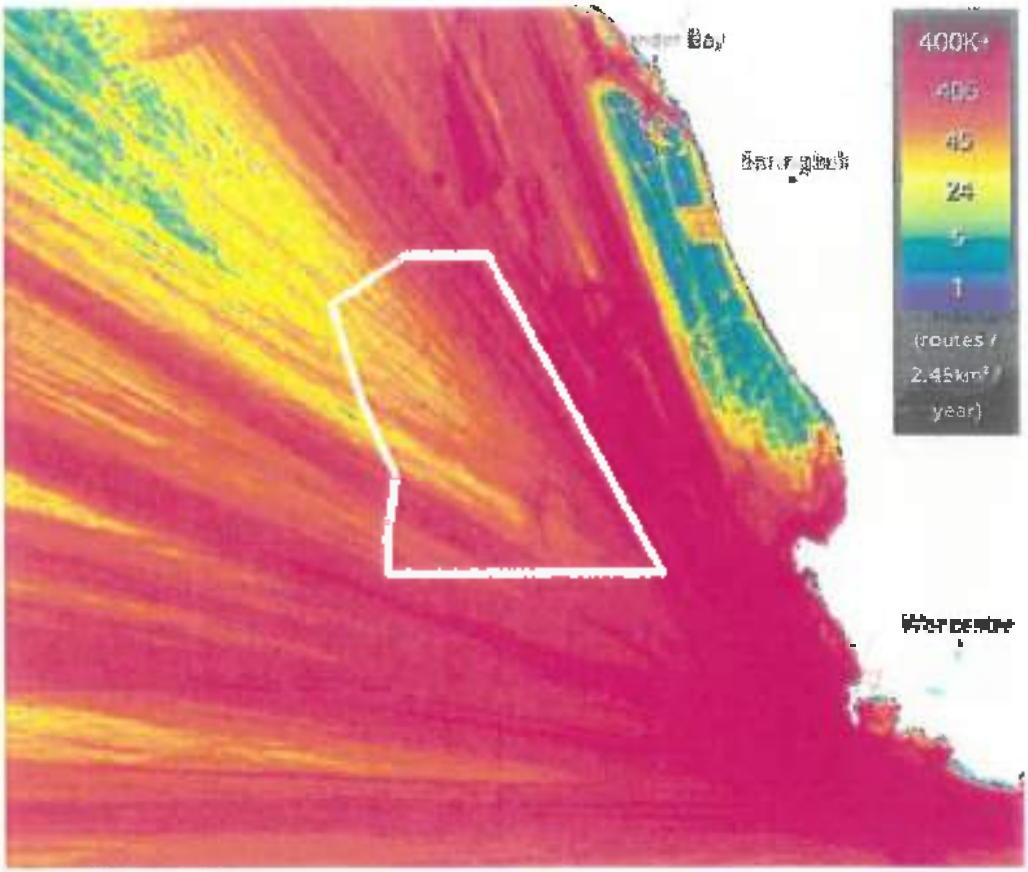

Figure 46: The Reconnaissance Permit Area (cyan polygon) in relation to offshore vessel traffic density (adapted from www.marinetraffic.com/en/ais/home).

The airguns used in modern seismic surveys produce some of the most intense non-explosive sound sources used by humans in the marine environment (Gordon *et al.* 2004), and are the second highest contributor of human-caused underwater noise in total energy output per year (Weilgart 2013). Until the demand for petroleum resources is substantially diminished and renewable energy resources can be adopted on a global scale, or alternatives to seismic surveys are found, seismic surveys will remain a major source of noise in the ocean (Przeslawski *et al.* 2018). However, the transmission and attenuation of seismic sound is probably of equal or greater importance in the assessment of environmental impacts than the produced source levels themselves, as transmission losses and attenuation are very site specific, and are affected by propagation conditions, distance or range, water and receiver depth and bathymetrical aspect with respect to the source array. In water depths of 25 - 50 m airgun arrays are often audible above ambient noise levels to ranges of 50 - 75 km, and with efficient propagation conditions such as experienced on the continental shelf or in deep oceanic water, detection ranges can exceed 100 km and 1 000 km[4], respectively (Bowles *et al.* 1991; Richardson *et al.* 1995; see also references in McCauley 1994). On analysing 10 years of recordings from the Mid-Atlantic Ridge, Nieukirk *et al.* (2012), found that airguns could be heard at distances of 4 000 km from the seismic vessels, and were audible for 80-95% of the time for more than 12 consecutive months in some locations.

[4] Audibility above ambient, however, does not imply impacts resulting in PTS, TTS or behavioural changes.

The signal character of seismic shots also changes considerably with propagation effects. Reflective boundaries include the sea surface, the sea floor and boundaries between water masses of different temperatures or salinities, with each of these preferentially scattering or absorbing different frequencies of the source signal. This results in the received signal having a different spectral makeup from the initial source signal. In shallow water (<50 m) at ranges exceeding 4 km from the source, signals tend to increase in length from <30 milliseconds, with a frequency peak between 10-100 Hz and a short rise time, to a longer signal of 0.25-0.75 seconds, with a downward frequency sweep of between 200 - 500 Hz and a longer rise time (McCauley 1994; McCauley *et al.* 2000).

In contrast, in deep water received levels vary widely with range and depth of the exposed animals, and exposure levels cannot be adequately estimated using simple geometric spreading laws (Madsen *et al.* 2006). These authors found that the received levels fell to a minimum between 5 - 9 km from the source and then started increasing again at ranges between 9 - 13 km, so that absolute received levels were as high at 12 km as they were at 2 km, with the complex sound reception fields arising from multi-path sound transmission.

Acoustic pressure variation is usually considered the major physical stimulus in animal hearing, but certain taxa are capable of detecting either or both the pressure and particle velocity components of a sound (Turl 1993). An important component of hearing is the ability to detect sounds over and above the ambient background noise. Auditory masking of a sound occurs when its' received level is at a similar level to background noise within the same frequencies. The signal to noise ratio required to detect a pure tone signal in the presence of background noise is referred to as the critical ratio.

The auditory thresholds of many species are affected by the ratio of the sound stimulus duration to the total time (duty cycle) of impulsive sounds of <200 millisecond duration. The lower the duty cycle the higher the hearing threshold usually is. Although seismic sound impulses are extremely short and have a low duty cycle at the source, received levels may be longer due to the transmission and attenuation of the sound (as discussed above).

Below follows a brief review of the impacts of seismic surveys on marine faunal communities. This information is largely drawn from McCauley (1994), McCauley *et al.* (2000), the Generic EMPR for Oil and Gas Prospecting off the Coast of South Africa (CCA & CMS 2001) and the very comprehensive review by Cetus Projects (2007), supplemented by more recent peer-reviewed literature available on the WWW. While the discussion and assessments focus primarily on marine mammals, the effects on pelagic and benthic invertebrates, fish, turtles and seabirds are also covered briefly.

The impact assessment table provided in each section provides a summary of the various impacts identified, with the significance rating for the pre-mitigation and residual impacts presenting the worst-case scenario.

4.3.1 Impacts of Seismic Noise on Whales and Dolphins

Source of Impact

The project activities that will result in impacts to marine cetaceans are listed below.

Project phase	Activity
Mobilisation	N/A
Operation	Seismic acquisition/ firing of airguns
Demobilisation	N/A

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition.

Impact Description

The potential impact of seismic survey noise on whales and dolphins could include physiological injury to individuals, behavioural avoidance of individuals (and subsequent displacement from key habitat), masking of important environmental or biological sounds and indirect effects due to effects on predators or prey.

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

Thirty three species or sub species/populations of cetaceans (whales and dolphins) are known or likely to occur off the West Coast. The majority of migratory cetaceans in South African waters are baleen whales (mysticetes), while toothed whales (odontocetes) may be resident or migratory. Of the 33 species, the blue whale is listed as 'Critically endangered', the fin and sei whales are 'Endangered' and the sperm, Bryde's (inshore) and humpback (B2 ppopulation) whales are considered 'Vulnerable' (South African Red Data list Categories). Due to its location offshore and proximity to important seabed features such as Tripp Seamount, Child's Bank and the Cape Canyon, the sensitivity of migratory cetaceans is thus considered to be HIGH. However, the numbers of individuals encountered during the survey are likely to be low because of the extensive distributions of the various species concerned.

Impact Assessment

Reactions of cetaceans to anthropogenic sounds have been reviewed by McCauley (1994), Richardson *et al.* (1995), Gordon & Moscrop (1996) and Perry (1998). More recently reviews have focused specifically on the effects of sounds from seismic surveys on marine mammals (DFO 2004; NRC 2005; Nowacek *et al.* 2007; Southall *et al.* 2007; Abgrall *et al.* 2008; Stone & Tasker 2006; Stone *et al.* 2017, amongst others).

0298

The factors that affect the response of marine mammals to sounds in their environment include the sound level and its prevailing acoustic characteristics, the ecological features of the environment in which the animal encounters the sound and the physical and behavioural state of the animal, and the ecological features of the environment in which the animal encounters the sound. When discussing the potential effects of seismic surveys on marine mammals we should bear in mind the lack of data (uncertainty) concerning the auditory capabilities and thresholds of impacts on the different species encountered and the individual variability in hearing thresholds and behavioural responses, which are likely to influence the degree of impact (Luke *et al.* 2009; Gedamke *et al.* 2011). Furthermore, there is growing recognition that the sub-lethal effects of noise disturbance, which are both difficult to identify and measure, are likely to be relatively widespread and may have a greater impact than direct physical injury (Forney *et al.* 2017). Depending on the duration and spatial scale of noise exposure, sub-lethal effects could be either acute (generally short-term and associated with a specific activity) or chronic (longer-term and associated with many overlapping activities). These authors point out that a lack of observed response does not imply an absence of costs such as physiological stress and reduced reproduction, survival or feeding success. Apparent tolerance of disturbance may in fact have population-level impacts that are more subtle and difficult to record with conventional methodologies.

This uncertainty and the variability in hearing thresholds and behavioural responses can have a large influence on how risk to marine mammals is assessed. Assessing the impact of seismic activity on populations off southern Africa is further hampered by a poor understanding of the abundance and distribution of many of the species found here.

Cetacean vocalisations

Cetacean are highly reliant on acoustic channels for orientation in their environment, feeding and social communication (Tyack & Clark 2000). Baleen whales produce a wide repertoire of sounds ranging in frequencies from 12 Hz to 8 kHz (Richardson *et al.* 1995; Erbe *et al.* 2017). Vocalisations may be produced throughout the year (Dunlop *et al.* 2007; Mussoline *et al.* 2012; Vu *et al.* 2012), with peaks in call rates during breeding seasons in some species, most notably humpback whales (Winn & Winn 1978).

Odontocetes produce a spectrum of vocalizations including whistles, pulsed sounds and echolocation clicks (Popper 1980; Erbe *et al.* 2017). Whistles play a key role in social communication, they are concentrated in the 1-30 kHz frequency range but may extend up to 75 kHz (Samarra *et al.* 2010) and contain high frequency harmonics (Lammers *et al.* 2003). The characteristics of burst pulsed sounds are highly variable, concentrated in the mid frequency for killer whales (Richardson *et al.* 1995), but extending well into the ultrasonic frequency range for other dolphin species (Lammers *et al.* 2003). Although most odontocete vocalizations are predominantly in mid and high frequency bands, there are recent descriptions of dolphins producing low frequency moans (150-240 Hz) and low frequency modulated tonal calls (990 Hz) (van der Woude 2009; Simrad *et al.* 2012; Erbe *et al.* 2017), the function of which remains unclear but may be related to social behaviours.

Clicks are high intensity, short sounds associated with orientation and feeding. The frequency composition of echolocation clicks varies with species (Erbe *et al.* 2017). Most delphinids produce broad band echolocation clicks with frequencies which extend well up into the ultra-sonic range > 100 kHz (Richardson *et al.* 1995). Sperm whales produce broadband echolocation clicks reaching up to 40 kHz in frequency (Backus & Schevill 1966; Madsen *et al.* 2002a, 2002b). Neonatal sperm whales produce lower frequency sounds at 300-1700 Hz (Madsen *et al.* 2003). Porpoise, Kogiids and dolphins

in the genus *Cephalorhynchus* (including the Heaviside's dolphin) produce characteristic narrow band, high frequency (NBHF) echolocation clicks with a central frequency around 125 kHz (Madsen *et al.* 2005a; Morisaka *et al.* 2011). Beaked whales produce low frequency sounds (Richardson *et al.*, 1995) and mid frequency echolocation clicks, burst pulse vocalisations and frequency modulated pulses with energy concentrated at 10 kHz and above (Madsen *et al.* 2005b; Rankin *et al.* 2011).

Cetacean hearing

Cetacean hearing has received considerable attention in the international literature, and available information has been reviewed by several authors including Popper (1980), Fobes & Smock (1981), Schusterman (1981), Ridgway (1983), Watkins & Wartzok (1985), Johnson (1986), Moore & Schusterman (1987) and Au (1993).

Marine mammals as a group have wide variations in ear anatomy, frequency range and amplitude sensitivity. The hearing threshold is the amplitude necessary for detection of a sound and varies with frequency across the hearing range (Nowacek *et al.* 2007). Hearing thresholds differ between odontocetes and baleen whales, and between individuals, resulting in different levels of sensitivity to sounds at varying frequencies. For most species, hearing sensitivity corresponds closely to the frequencies at which they vocalise, however it is likely that hearing range is broader than vocalisation range (Bradley & Stern 2008). Consequently, baleen whale hearing is centred at below 1 kHz (Fleischer 1976, 1978; Norris & Leatherwood 1981), while toothed whale and dolphin hearing is centred at frequencies of between 10 and 100 kHz (Richardson *et al.* 1995). The combined information strongly suggests that baleen whales are likely to be most sensitive to sounds from 10's of Hz to around 10 kHz (Southall *et al.* 2007), while toothed whale and dolphin hearing is centred at frequencies of between 10 and 100 kHz (Richardson *et al.* 1995).

Behavioural and electrophysical audiograms are available for several species of small- to medium-sized toothed whales (killer whale: Hall & Johnson 1972; Bain *et al.* 1993, false killer whale: Thomas *et al.* 1988, bottlenose dolphins: Johnson 1967, beluga: White *et al.* 1978; Awbrey *et al.* 1988, Harbour porpoise: Andersen 1970, Chinese river dolphin: Ding Wang *et al.* 1992 and Amazon river dolphin: Jacobs & Hall 1972; Risso's dolphin: Nachtigall *et al.* 1995, 1996, Harbour porpoise: Lucke *et al.* 2009). In these species, hearing is centered at frequencies between 10 and 100 kHz (Richardson *et al.* 1995). The high hearing thresholds at low frequency for those species tested implies that the low frequency component of seismic shots (10 - 300 Hz) will not be audible to the small to medium odontocetes at any great distance. However, the higher frequency of an airgun array shot, which can extend to 15 kHz and above (Madsen *et al.* 2006) may be audible from tens of kilometres away, due to the very low sensitivity thresholds of many toothed whales at frequencies exceeding 1 kHz. For example, Sarnocińska *et al.* (2020) reported a decrease in echolocation signals of harbour porpoise in response to airgun signals 6-12 km away, potentially indicating temporary displacement from the area or changes in foraging behaviour (but see also Pirotta *et al.* 2014; Thompson *et al.* 2013).

No psycho-acoustical or electrophysical work on the sensitivity of baleen whales to sound has been conducted (Richardson *et al.* 1995) and hypotheses regarding the effects of sound in baleen whales are extrapolations from what is known to affect odontocetes or other marine mammals and from observations of behavioural responses. A partial response "audiogram" exists for the gray whale based on the avoidance of migrating whales to a pure tone source (Dahlheim & Ljungblad 1990). Humpback whales in the wild have been reported to detect sounds ranging from 10 Hz to 10 kHz at levels of 102 to 106 dB re 1 µPa (Frankel *et al.* 1995, in Perry 1998; Frankel & Clark 2000). Blue whales and Blainville's beaked reduce calling in the presence of mid-frequency sonar (1-8 kHz)

providing evidence that they are receptive to sound in this range (Melcón *et al.* 2012; McCarthy *et al.* 2011), and evidence exists for changes in humpback whale vocalisation in response to low-frequency sonar as much as 200 km away (Miller *et al.* 2000; Risch *et al.* 2012).). Based on the low frequency calls produced by larger toothed whales, and anatomical and paleaontological evidence for baleen whales, it is predicted that these whales hear best in the low frequencies (Fleischer 1976, 1978; McCauley 1994), with hearing likely to be most acute below 1 kHz (Fleischer 1976, 1978; Norris & Leatherwood 1981). The available information demonstrates that the larger toothed whales and baleen whales will be very receptive to the sound produced by seismic airgun arrays and consequently this group may be more affected by this type of disturbance than smaller toothed whales (Morton & Symonds 2002; Nowacek *et al.* 2007).

Overlap between the frequency spectra of seismic shots and the hearing threshold curve with frequency for some toothed whale species, suggests that these may react to seismic shots at long ranges, but that hearing damage from seismic shots is only likely to occur at close range. They will thus not be affected as severely as many fish, and possibly sea turtles and baleen whales that have their greatest hearing sensitivity at low frequencies (McCauley 1994).

Physiological injury and stress

Exposure to high sound levels can result in physiological injury to cetaceans through a number of avenues, including shifts of hearing thresholds (as either PTS or TTS) (Richardson *et al.* 1995; Au *et al.* 1999; Schlundt *et al.* 2000; Finneran *et al.* 2000, 2001, 2002, 2003), tissue damage (Lien *et al.* 1993; Ketten *et al.* 1993), acoustically induced decompression sickness particularly in beaked whales (Crum & Mao 1996; Cox *et al.* 2006), and non-auditory physiological effects including elevated blood pressures, increased heart and respiration rates, and temporary increases in blood catecholamines and glucocorticoids (Bowles & Thompson 1996), which may have secondary impacts on reproduction. Most studies conducted on sound-related injuries in cetaceans, however, investigated the effects of explosive pulses (Bohne *et al.* 1985, 1986; Lien *et al.* 1993; Ketten *et al.* 1993) and mid-frequency sonar pulses (Simmonds & Lopez-Jurado 1991; Crum & Mao 1996; Frantzis 1998; Balcomb & Claridge 2001; Evans & England 2001; Jepson *et al.* 2003; Cox *et al.* 2006), and the results are thus not directly applicable to non-explosive seismic sources such as those from airgun arrays.

Both PTS and TTS represent actual changes in the ability of an animal to hear, usually at a particular frequency, whereby it is less sensitive at one or more frequencies as a result of exposure to sound (Nowacek *et al.* 2007). Southall *et al.* (2007) propose a dual criterion for assessing injury from noise based on the peak sound pressure level (SPL) and sound exposure level (SEL) (a measure of injury that incorporates the sound pressure level and duration), with the one that is exceeded first used as the operative injury criterion. For a pulsed sound source such as that generated during seismic seabed surveys, the maximum levels for PTS are 230 dB re:1 µPa (peak) and 203 re:1 µPa2-s for SPL and SEL respectively for the various marine mammal functional hearing groups (Table 11). For TTS these values are 226 dB re:1 µPa (peak) and 188 dB re:1 µPa2-s for SPL and SEL, respectively. There is thus a range at which permanent or temporary hearing damage might occur, although some hearing damage may already occur when received levels exceed 1 838 dB re:1 µPa2-s SEL. The behavioural disruptive threshold for impulsive noise for all functional groups is root-mean-square (RMS) SPL of 160 dB re 1µPa (NMFS 2013).

Table 11: The Permanent Threshold Shift (PTS) and Temporary Threshold Shift (TTS) levels for marine mammal functional hearing groups exposed to either single or multiple impulsive noise events within a 24-h period (Southall *et al.* 2019).

Marine mammal hearing group	PTS and TTS threshold levels - impulsive noise events			
	Injury (PTS) onset		TTS onset	
	Pk SPL, dB re 1µPa	Weighted SEL_{24h}, dB re 1µPa²·s	Pk SPL, dB re 1µPa	Weighted SEL_{24h}, dB re 1µPa²·s
Low-frequency cetaceans (mysticetes: southern right, humpback, sei, fin, blue, Bryde's, minke)	219	183	213	168
High-frequency cetaceans (odontocetes: dolphins, toothed, beaked, and bottle nose whales)	230	185	224	170
Very high-frequency cetaceans (Heaviside's dolphins, dwarf and pygmy sperm whales)	202	155	196	140
Sirenians (dugongs, manatees)*	226	203	220	175
Phocid carnivores in water (true seals)*	218	185	212	170
Other marine carnivores in water (sea lions, fur seals)	232	203	226	188

* do not occur in Orange Basin

Based on statistical simulations accounting for uncertainty in the available data and variability in individual hearing thresholds, Gedamke *et al.* (2011) conclude that the possibility of seismic activity leading to TTS in baleen whales must be considered at distances up to several kilometers. As cetaceans are highly reliant on sound, hearing damage leading to TTS and PTS is likely to result in a reduction in foraging efficiency, reproductive potential, social cohesion and ability to detect predators (Weilgart 2007). Results of the sound modelling study for the present survey are presented later.

Noise induced stress resulting from exposure to sources of marine sound can cause detrimental changes in blood hormones, including cortisol (Romano *et al.* 2004). The timing of the stressor relative to seasonal feeding and breeding cycles (such as those observed in migrating baleen whales) may influence the degree of stress induced by noise exposure (Tyack 2008). However, quantifying stress caused by noise in wild populations is difficult as it is not possible to determine the physiological responses of an animal to a noise stressor based on behavioural observations alone (Wright *et al.* 2007). It can, however, negatively affect reproduction, immune systems, growth, health, and other important life functions (Rolland *et al.* 2012; Lemos *et al.* 2021). One recent study was able to identify a reduction in stress-related faecal hormone metabolites (glucocorticoids) in North Atlantic right whales concurrent with a 6 dB reduction in shipping noise. This study provided the first evidence that exposure to low-frequency ship noise may be associated with chronic stress in whales (Rolland *et al.* 2012).

Behavioural disturbance

The factors that affect the response of marine mammals to sounds in their environment include the sound level and other properties of the sound, the physical and behavioural state of the animal and its prevailing acoustic characteristics, and the ecological features of the environment in which the animal encounters the sound. The responses of cetaceans to noise sources are often also dependent on the perceived motion of the sound source, as well as the nature of the sound itself. For example, many whales are more likely to tolerate a stationary source than they are one that is approaching them (Watkins 1986; Leung-Ng & Leung 2003), or are more likely to respond to a stimulus with a sudden onset than to one that is continuously present (Malme *et al.* 1985).

The speed of sound increases with increasing temperature, salinity and pressure (Richardson *et al.* 1995) and stratification in the water column affects the rate of propagation loss of sounds produced by an airgun array. As sound travels, acoustic shadow and convergence zones may be generated as sound is refracted towards areas of slower sound speed. These can lead to areas of high and low noise intensity (shadow zones) so that exposure to different pulse components at distances of 1-13 km from the seismic source does not necessarily lessen (attenuate) with increasing range. In some cases this can lead to received levels at 12 km being as high as those at 2 km (Madsen *et al.* 2006). Depending on the propagation conditions of the water column, animals may need to move closer to the sound source or apply vertical rather than horizontal displacement to reduce their exposure, thus making overall avoidance of the sound source difficult. Although such movement may reduce received levels in the short-term it may prolong the overall exposure time and accumulated SEL (Madsen *et al.* 2006). Results of the sound modelling study for the present survey are presented later.

Typical behavioural response in cetaceans to seismic airgun noise include initial startle responses (Malme *et al.* 1985; Ljungblad *et al.* 1988; McCauley *et al.* 2000), changes in surfacing behaviour (Ljungblad *et al.* 1988; Richardson *et al.* 1985a; McCauley *et al.* 1996, 2000), shorter dives (Ljungblad *et al.* 1988; Robertson *et al.* 2013; Dunlop *et al.* 2015), changes in respiration rate (Ljungblad *et al.* 1988; Richardson *et al.* 1985a, 1985b; Malme *et al.* 1983, 1985,1986), slowing of travel (Malme *et al.* 1983, 1984; Dunlop *et al.* 2015, 2017a, 2017b), and changes in vocalisations (McDonald *et al.* 1993, 1995; Castellote *et al.* 2012; Sarnocińska *et al.* 2020) and call rate (Di Iorio & Clarke 2010; Blackwell *et al.* 2013, 2015). These subtle changes in behavioural measures are often the only observable reaction of whales to reception of anthropogenic stimuli, and there is no evidence that these changes are biologically significant for the animals (see for example McCauley 1994). Possible exceptions are impacts at individual (through reproductive success) and population level through disruption of feeding within preferred areas (Western gray whales: Weller *et al.* (2002); blue whales: Goldbogen *et al.* 2013; Friedlaender *et al.* 2016; sperm whales: Farmer *et al.* 2018; harbour porpoise: Sarnocińska *et al.* 2020). For continuous noise, whales begin to avoid sounds at exposure levels of 110 dB, and more than 80% of species observed show avoidance to sounds of 130 dB re:1µPa. For seismic noise, most whales show avoidance behaviour above 160 dB re:1µPa (Malme *et al.* 1983, 1984; Ljungblad *et al.* 1988; Pidcock *et al.* 2003), with displacement from the noise impacted area potentially persisting for an extended period (Yazvenko *et al.* 2007; Castellote *et al.* 2012).. Behavioural responses are often evident beyond 5 km from the sound source (Ljungblad *et al.* 1988; Richardson *et al.* 1986, 1995; NMFS 2013; Kavanagh *et al.* 2019; Sarnocińska *et al.* 2020), with the most marked avoidance response recorded by Kolski and Johnson (1987) who reported bowhead whales swimming rapidly away from an approaching seismic vessel at a 24 km distance. More recently, basin-wide effects of seismic surveys on cetacean sightings and calling behaviour have been reported (Blackwell *et al.* 2015; Kavanagh *et al.* 2019; Kyhn *et al.* 2019; see also Nieukirk *et al.* 2012).

In an analysis of marine mammals sightings recorded from seismic survey vessels in United Kingdom waters, Stone (2003) reported that responses to large gun seismic activity varied between species, with small odontocetes showing the strongest avoidance response (Stone 2003; Stone & Tasker 2006). Responses of medium and large odontocetes (killer whales, pilot whales and sperm whales) were less marked, with sperm whales showing no observable avoidance effects (see also Rankin & Evans 1998; Davis *et al.* 2000; Madsen *et al.* 2006), but may be affected at greater ranges than currently regulated due to subtle effects on their foraging behaviour (Miller *et al.* 2009; Farmer *et al.* 2018). Baleen whales showed fewer responses to seismic survey activity than small odontocetes, and although there were no effects observed for individual baleen whale species, fin and sei whales were less likely to remain submerged during firing activity. All baleen whales showed changes in behavioural responses further from the survey vessel (see also Ljungblad *et al.* 1988; McCauley 2000; Abgrall *et al.* 2008), and both orientated away from the vessel and altered course more often during shooting activity. The author suggests that different species adopt different strategies in response to seismic survey disturbance, with faster smaller odontocetes fleeing the survey area (e.g. Weir 2008; van Beest *et al.* 2018), while larger slower moving baleen whales orientate away from and move slowly from the firing guns, possibly remaining on the surface as they do so (see also Richardson *et al.* 1985a, 1985b, 1986, 1995). Responses to small airguns were less, and although no difference in distance to firing and non-firing small airguns were recorded, there were fewer sightings of small odontocetes in association with firing airguns. Other reports suggest that there is little effect of seismic surveys on small odontocetes such as dolphins (e.g. Pirotta *et al.* 2014; Thompson *et al.* 2013; van Beest *et al.* 2018), as these have been reported swimming near or riding the bow-waves of operating seismic vessels (Duncan 1985; Evans & Nice 1996; Abgrall *et al.* 2008; but see also Schlundt *et al.* 2000). Recent evidence has, however, shown that for small, localised odontocete populations exhibiting high site fidelity, displacement away from the ensonified area may itself pose a biological risk. Although the consequences of displacement are poorly understood, they likely include increased stress and reduce foraging success, with associated effects on survival and reproduction (Forney *et al.* 2017).

McCauley *et al.* (1996, 2000) found no obvious evidence that humpback whales were displaced by 2D and 3D seismic surveys and no apparent gross changes in the whale's migratory path could be linked to the seismic survey (but see Dunlop *et al.* 2016, 2017). Localised avoidance of the survey vessel during airgun operation was however noted within 4 km of the source at levels over 130 re 1 $\mu Pa^2 s^{-1}$ (Dunlop *et al.* 2017a, 2018) as was a reduction in social interactions among whales (Dunlop *et al.* 2020). Whales which are not migrating but using the area as a calving or nursery ground may be more seriously affected through disturbance of suckling or resting. Potential avoidance ranges of 7-12 km by nursing animals and >4 km for migrating humpbacks have been suggested, although these might differ in different sound propagation conditions (McCauley *et al.* 2000; Dunlop *et al.* 2017a, 2017b; Ellison *et al.* 2018). Base on the noise exposure criteria of RMS SPL 160 dB re 1µPa provided by Popper *et al.* (2014), the sound transmission loss modelling study undertaken for the current project (SLR 2022) identified that for 3D acquisition, the maximum horizontal threshold distance from the source to impact behavioural threshold levels for marine mammals was 3.8 km. Disturbance of mating behaviour (which could involve a high degree of acoustic selection) by seismic noise could be of consequence to breeding animals.

Masking of important environmental or biological sounds

Potential interference of seismic emissions with acoustic communication in cetaceans includes direct masking of the communication signal, temporary or permanent reduction in the hearing capability of the animal through exposure to high sound levels or limited communication due to behavioural

changes in response to the seismic sound source. Masking can both reduce the range over which the signals can be heard and the quality of the signal's information (Weilgart *et al.* 2007). Marked differences occur in the hearing of baleen whales and toothed whales and dolphins. The vocalisation and estimated hearing range of baleen whales (centred at below 1 kHz) overlap the highest peaks of the power spectrum of airgun sounds and consequently these animals may be more affected by disturbance from seismic surveys (Nowacek *et al.* 2007). Whales may respond to masking by calling more frequently, calling louder, calling less frequently (Weilgart *et al.* 2007a, 2007b; Cholewiak *et al.* 2018) or showing no change in calling behaviour (Madsen *et al.* 2002). For example, it has been reported that blue whales called consistently more on days when seismic exploration was taking place, presumably to compensate for the elevated ambient noise levels (Di Iorio & Clarke 2010). More recently, Blackwell *et al.* (2013, 2015) determined that bowhead whales increased calling rates as soon as airgun pulses were detectable, with calling rates leveling off at a received cumulative SEL of ~94 dB re 1 μPa^2, but decreasing once $CSEL_{10\text{-min}}$ exceeded ~127 dB re 1 μPa^2 and ceasing altogether when $CSEL_{10\text{-min}}$ values were above ~160 dB re 1 μPa^2. Similarly, Cerchio *et al.* (2014) reported decreased singing activity in humpbacks off Northern Angola in response to increasing seismic noise, with possible implications on breeding displays by males, which in turn could result in decreased reproductive success).

The masking effect of seismic pulses might be reduced by their intermittent production. However, the length of seismic pulses increases with distance from the source, thereby increasing the potential to cause masking at range (Gordon *et al.* 2004). Toothed whales vocalise at much higher frequencies of between 10 and 100 kHz, and it is likely that clicks are not masked by seismic survey noise (Goold & Fish 1998). However, due to multi-path propagation, receivers (cetaceans) can be subject to several versions of each airgun pulse, which have very different temporal and spectral properties (Madsen *et al.* 2006). High frequency sound is released as a by-product of airgun firing and this can extend into the mid- and high-frequency range (up to and exceeding 15 kHz) so that the potential for masking of these sound sources should also be considered (Madsen *et al.* 2006).

Indirect effects on prey species

Exposure to seismic airguns can cause hearing damage to fish (reviewed in Popper & Schilt 2008) and several studies have linked seismic exploration with short-term reductions in fish abundance and changes in distribution away from the seismic survey area (Engås *et al.* 1995; Slotte *et al.* 2004). The majority of baleen whales will undertake little feeding within breeding ground waters and rely on blubber reserves during their migrations. Therefore they may not be affected by changes in fish distribution. Although the fish and cephalopod prey of toothed whales and dolphins may be affected by seismic surveys, impacts will be highly localised and small in relation to the feeding ranges of cetacean species, but cumulative impacts within species ranges must be considered.

Consequence of Impact

Marked differences occur in the hearing of baleen whales (mysticete cetaceans) and toothed whales and dolphins (odontocete cetaceans). The vocalisation and estimated hearing range of baleen whales (centred at below 1 kHz) overlap the highest peaks of the power spectrum of airgun sounds and consequently these animals may be more affected by disturbance from seismic surveys (Nowacek *et al.* 2007). In contrast, the hearing of toothed whales and dolphins is centred at frequencies of between 10 and 100 kHz, suggesting that these may react to seismic shots at long ranges, but that hearing damage from seismic shots is only likely to occur at close range. Mysticete and odontocete cetaceans are thus assessed separately below.

Physiological injury

There is little information available on the levels of noise that would potentially result in physiological injury to cetaceans, and no permanent threshold shifts have been recorded. Available information suggests that the animal would need to be in close proximity to operating airguns to suffer physiological injury, and being highly mobile it is assumed that they would avoid sound sources at distances well beyond those at which injury is likely to occur. Deep-diving cetacean species (e.g. sperm whales) may, however, be more susceptible to acoustic injury, particularly in the case of seafloor-focussed seismic surveys, where the downward focussed impulses could trap deep diving cetaceans within the survey pulse, as escaping towards the surface would result in exposure to higher sound level pulses.

Due to the high level of impulsive signal emissions from the array source, marine mammals are predicted to experience a PTS at close proximity to the source array due to the immediate exposure to individual pulses. The Underwater Noise Modelling Study undertaken for the proposed 3D survey area in the Orange Basin (SLR 2022) identified that the low-frequency cetaceans expected to occur in the Reconnaissance Permit Area (e.g. southern right, humpback, fin, sei, blue, Bryde's, minke) were predicted to experience PTS effects within approximately 45 m from the 3D source array, at all assessed water depth scenarios, with the the zone of TTS due to a single pulse exposure predicted within approximately 90 m from the source array (Table 12). High-frequency cetaceans (e.g. sperm, killer and beaked whales and the diversity of dolphins) and very high frequency cetaceans (e.g. pygmy sperm whale and dwarf sperm whale) were expected to experience PTS within approximately 21 m from the source array and 325 m from the source array, respectively (Table 12). The maximum threshold distance for TTS onset for very-high frequency cetaceans occurs within 650 m from the array source.

Among marine mammals expected to occur in the Reconnaissance Permit Area, low-frequency cetaceans have the highest zones of PTS and TTS impact from multiple pulses (i.e. the maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels). The zones of PTS impact are predicted to range up to 340 m from the adjacent survey lines for the typical 24-hour survey operation scenario considered, with the maximum zones of TTS impact for low frequency cetaceans predicted to be around 5 050 m from the adjacent survey lines (Table 12) (SLR 2022). It must be kept in mind that the cumulative zones of impact are conservative, and that being highly mobile, whales and dolphins are thus likely to have moved considerable distances over the cumulative 24-hr period. Cumulative effects would only be expected where the animals do not move away from the area, e.g. from specific coastal areas used as calving sites or from mid-ocean focal sites such as Child's Bank and Tripp Seamount.

For high-frequency cetaceans it was predicted that the cumulative PTS and TTS onset criteria for the 24-hour survey operation scenario would not to be reached (Table 12). In the case of very high frequency cetaceans, the zones of PTS impact for the cumulative scenario are predicted to range up to 40 m from the adjacent 3D survey lines, for the typical 24-hour survey operation scenario considered, with the zones of TTS impact predicted to range to 1 200 m from the adjacent 3D survey lines (Table 12).

The majority of baleen whales migrate to the southern African subcontinent to breed during winter months. Humpback whales migrating north strike the coast at varying places mostly north of St Helena Bay resulting in increasing whale density on shelf waters and into deeper pelagic waters as one moves northwards, but no clear migration 'corridor'. The northern migration would begin passing through

the project area around April, continuing through to September/October when the southern migration begins and continues through to January/February. Southern right whales arrive in coastal waters in June, building up to a maximum in August/September and departing again in November. The Orange Basin thus lies within the migration paths of humpback and southern right whales, but well offshore of inshore coastal areas frequented by southern right whales for mating and breeding. As the survey is proposed for the summer months (December to May) encounters with migrating whales should be minimal, although some humpbacks on their return journey in November/December and those remaining on the summer feeding grounds off Cape Columbine may still be encountered. However, the survey is likely to frequently encounter resident odontocetes such as common dolphin, Risso's dolphin and pilot whales, which are present year-round, and may encounter sperm whales, particularly in winter.

Table 12: Zones of immediate and cumulative impact from single and multiple pulses for PTS and TTS for the marine mammal groups likely to occur in the Orange Basin area (from Lewis 2022).

Marine mammal hearing group	Zones of impact - maximum horizontal distances from source to impact threshold levels (from single 3D pulses)		Zones of impact - maximum horizontal perpendicular distances from assessed 3D survey lines to cumulative impact threshold levels	
	Injury (PTS) onset	TTS onset	Injury (PTS) onset	TTS onset
Low-frequency cetaceans (mysticetes: southern right, humpback, sei, fin, blue, Bryde's, minke)	45 m	90 m	340 m	5050 m
High-frequency cetaceans (odontocetes: dolphins, toothed whales (e.g. sperm), beaked whales, bottle-nose whales)	21 m	27 m	-	-
Very High-Frequency cetaceans (Heaviside's dolphins, pygmy sperm and dwarf sperm whale	325 m	650 m	40 m	1 200 m
Other marine carnivores in water (sea lions, fur seals)	19 m	24 m	-	-

Note: a dash indicates the threshold is not applicable.

Although the current distribution of the offshore population of Bryde's whales is located inshore of the proposed 3D survey area (Harris et al. 2022), it may be encountered in the inshore portions of the survey area in the Orange Basin during the summer survey period as its seasonality on the West Coast is opposite to the majority of the balaenopterids with abundance likely to be highest in the broader project area in January - March.

Assuming the survey is scheduled so as to avoid the key migration period (early June to late November), there would be a low likelihood of encountering migrating humpback and southern right whales, but a high likelihood of encountering offshore Bryde's whales. The impact of potential physiological injury to mysticete and odontocete cetaceans as a result of seismic sounds is thus

J428

deemed to be of HIGH intensity. Furthermore, as the duration of the impact would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL), the potential for physiological injury is therefore considered to be of MEDIUM consequence for resident mysticetes and odontocetes.

Behavioural disturbance

Avoidance of seismic survey activity by cetaceans, particularly mysticete species, begins at distances where levels of approximately 150 to 180 dB are received. More subtle alterations in behaviour may occur at received levels of 120 dB. The Underwater Noise Modelling Study undertaken for the proposed 3D survey area (SLR 2022) identified that the zones of behavioural disturbance for cetaceans caused by the immediate exposure to individual pulses was within 3.8 km from the 3D array source, assuming a SPL criteria of 160 dB re 1µPa. Although behavioural avoidance of seismic noise in the proposed survey area by baleen whales is highly likely, such avoidance is generally considered of minimal impact in relation to the distances of migrations of the majority of baleen whale species.

The timing of the survey relative to seasonal breeding cycles (such as those observed in migrating baleen whales) may influence the degree of stress induced by noise exposure (Tyack 2008). Displacement from critical habitat is particularly important if the sound source is located at an optimal feeding or breeding ground or areas where mating, calving or nursing occurs. For example, persistent disturbance of foraging behaviour in response to seismic noise can result in reductions in relative fitness of reproductive female Sperm whales leading to abortions and calf abandonment (Farmer *et al.* 2018), with mid-frequency sonars shown to reduced foraging efficiency in blue whales (Goldbogen *et al.* 2013). Species that feed intensively within a season and depend on dense prey concentrations can therefore experience significant population consequences, which in turn may pose significant risks to the recovery rates of endangered populations. Based on this knowledge, Norway has since 2019, recommended that seismic activity be restricted in areas and periods with intensive feeding of baleen whales (Sivle *et al.* 2021).

The survey area overlaps with the migration routes of humpback whales to and from their breeding grounds. The survey area is located well offshore of the coastal migration route for southern right whales. Although encounter rates peak in migration periods, humpback whales are found off the West Coast year round. For other species, the paucity of fine scale data from offshore waters on the distribution and seasonal occurrence of most cetacean species prevents prediction where such critical habitat might be with any certainty. Other baleen whale species are also found year round or have seasonal occurrences, although not well known, but existing data shows year-round presence of mysticetes. However, if the survey is scheduled to occur outside of the main winter northward and southward migration periods (June and November), interactions with migrating whales should be low.

Of greater concern than general avoidance of migrating whales is avoidance of critical breeding habitat or area where mating, calving or nursing occurs. The humpback whales have their winter breeding concentrations off tropical west Africa, between Angola and the Gulf of Guinea and therefore over 1 000 km to the north-east of the proposed 3D survey area in the Orange Basin. Southern right whales currently have their most significant winter concentrations on the South Coast of South Africa between Port Elizabeth and Cape Town but are seen regularly off the southern half of Namibia, and would therefore pass along the West Coast. However, as the survey area is located in excess of 200 km offshore, there should be no overlap with potential coastal nursery areas for this species.

Assuming the survey is scheduled so as to avoid the key northward and southward migration periods (early June and late November, respectively), there is a low likelihood of encountering migrating humpback whales. However, due to the increasing numbers of southern right and humpback whales year round off the southern African West Coast and the Bryde's whales with migration periods opposite to the typical winter migrations, the potential impact of behavioural avoidance of seismic survey areas by mysticete cetaceans is considered to be of HIGH intensity (resident species), across the Reconnaissance Permit Area (REGIONAL) and for the duration of the survey (IMMEDIATE - 1.5 months). Considering the distribution ranges of most species of cetaceans, the impact of seismic surveying in the Orange Basin is considered of MEDIUM consequence for both migrating mysticetes and for resident whales, or Bryde's whales that show seasonality opposite to most balaenopterids.

Information available on behavioural responses of toothed whales and dolphins to seismic surveys is more limited than that for baleen whales. No seasonal patterns of abundance are known for odontocetes occupying the proposed 3D survey area but several species are considered to be year-round residents. Furthermore, a number of toothed whale species have a more pelagic distribution thus occurring further offshore, with species diversity and encounter rates likely to be highest on the shelf slope. The impact of seismic survey noise on the behaviour of toothed whales is considered to be of HIGH intensity across the proposed survey area (REGIONAL) and for the duration of the survey (IMMEDIATE - 1.5 months). The overall consequence will however not vary between species, and will be MEDIUM.

Masking of important environmental or biological sounds

Baleen whales appear to vocalise almost exclusively within the frequency range of the maximum energy of seismic survey noise, while toothed whales vocalise at frequencies higher than these. As the by-product noise in the mid- and high frequency range (up to and exceeding 15 kHz) can travel far (at least 8 km), masking of communication sounds produced by whistling dolphins and blackfish[5] is likely (Madsen *et al.* 2006). In the migratory baleen whale species, vocalisation increases once they reach the breeding grounds and on the return journey in November/December when accompanied by calves. Although most mother-calf pairs tend to follow a coastal route southwards, there is no clear migration corridor and humpbacks can be spread out widely across the shelf and into deeper pelagic waters. Vocalisation of southward migrating whales may thus potentially be regionally comparatively high on commencement of operations in December, reducing thereafter. However, masking of communication signals is likely to be limited by the low duty cycle of seismic pulses. Should the survey overlap with the key migration and breeding period when there is a high likelihood of encountering migrating Humpback whales (including possible mother-calf pairs) and no other mitigation measures are in place, the intensity of impacts on baleen whales is likely to be HIGH (mother-calf pairs) over the survey area (REGIONAL) and IMMEDIATE-TERM duration (1.5 months), and of MEDIUM intensity (species specific) in the case of toothed whales over the survey area (REGIONAL) and duration (IMMEDIATE - 1.5 months). The consequence for both mysticetes and odontocets would be MEDIUM.

Indirect impacts due to effects on prey

As with other vertebrates, the assessment of indirect effects of seismic surveys on resident odontocete cetaceans is limited by the complexity of trophic pathways in the marine environment.

[5] The term blackfish refers to the delphinids: melon-headed whale, killer whale, pygmy killer whale, false killer whale, long-finned pilot whale, short-finned pilot whale

Although the fish and cephalopod prey of toothed whales and dolphins may be affected by seismic surveys, impacts will be highly localised and small in relation to the feeding ranges of cetacean species. Although the majority of baleen whales will undertake little feeding within breeding-ground waters along the southern African west coast and rely on blubber reserves during their migrations there is increasing evidence that some species (fin whales, southern rights and humpbacks) are using upwelling areas off the South African West Coast as summer feeding grounds. The upwelling zone off Cape Columbine has become an important summer feeding area, and baleen whales have been reported to feed inshore of the Reconnaissance Permit area between St Helena Bay and Cape Town. Any indirect effects on their food source would thus be of VERY LOW intensity over the survey area (REGIONAL) and duration (IMMEDIATE - 1.5 months) and therefore of VERY LOW consequence. In the case of odontocetes, the broad ranges of prey species (in relation to the avoidance patterns of seismic surveys of such prey species) suggest that indirect impacts due to effects on prey would similarly be of LOW intensity over the survey area (REGIONAL) and duration (IMMEDIATE - 1.5 months) and therefore of VERY LOW consequence.

Impact Significance

Physiological injury and mortality

The potential impact of seismic noise on physiological injury of mysticetes and odontocetes, considering their high sensitivity, the high probability of the impact occurring and the medium consequence, is deemed to be of **MEDIUM** significance.

Behavioural avoidance

The potential impact of seismic noise on behevioural changes in mysticetes and odontocetes, considering their high sensitivity, the high probability of the impact occurring and the medium consequence, is deemed to be of **MEDIUM** significance.

Masking of Sounds and Communication

The potential impact of seismic noise on the masking of environmental sounds and communications in mysticetes and odontocetes, considering their high sensitivity, the high probability of the impact occurring and the medium consequence, is deemed to be of **MEDIUM** significance.

Indirect impacts due to effects on predators or prey

The potential indirect impact of seismic noise on food sources of mysticetes and odontocetes, considering their high sensitivity, the low likelihood of the impact occurring and the very low consequence, is thus deemed to be of **VERY LOW** significance.

Identification of Mitigation Measures

No.	Mitigation Measure	Classification
1. Survey Planning		
1.1	Plan seismic surveys to avoid movement of migratory cetaceans (particularly baleen whales) from their southern feeding grounds into low latitude waters (June to November inclusive), and their aggregation on the summer feeding grounds between St Helena Bay and Dassen Island from late October to late December and ensure that migration paths are not blocked by seismic operations. If possible the survey should be undertaken from North to South to avoid these feeding aggregations.	Avoid
1.2	Plan survey, as far as possible, so that the first commencement of airgun firing in a new area (including gun tests) is undertaken during daylight hours.	Abate on site
1.3	Prohibit airgun use (including airgun tests) outside of the area of operation (which includes line turns undertaken outside the Reconnaissance Permit area).	Avoid
1.4	Although a seismic vessel and its gear may pass through a declared Marine Protected Area, acoustic sources (airguns) must not be operational during this transit.	Avoid
2. Key Equipment		
2.1	**Passive Acoustic Monitoring (PAM)**	
2.1.1	Ensure the seismic vessel is fitted with Passive Acoustic Monitoring (PAM) technology, which detects some animals through their vocalisations.	Abate on site
2.1.2	As the survey area would largely be in waters deeper than 1 000 m where sperm whales and other deep-diving odontoceres are likely to be encountered, implement the use of PAM 24-hr a day when the sound source are in operation.	Abate on site
2.1.3	Ensure the PAM streamer is fitted with at least four hydrophones, of which two are HF and two LF, to allow directional detection of cetaceans.	Abate on site
2.1.4	Ensure the PAM hydrophone streamer is towed in such a way that the interference of vessel noise is minimised.	Abate on site
2.1.5	Ensure spare PAM hydrophone streamers (e.g. 4 heavy tow cables and 6 hydrophone cables) are readily available in the event that PAM breaks down, in order to ensure timeous redeployment.	Abate on site
2.2	**Acoustic Source**	
2.2.1	Define and enforce the use of the lowest practicable airgun volume for production, and design arrays to maximise downward propagation, minimise horizontal propagation and minimise high frequencies in airgun pulses.	Abate on site
2.2.2	Ensure a display screen for the acoustic source operations is provided to the marine observers. All information relating to the activation of the acoustic source and the power output levels must be readily available to support the observers in real time via the display screen and to ensure that operational capacity is not exceeded.	Abate on site
2.2.3	Ensure the ramp-up noise volumes do not exceed the production volume.	Abate on site

No.	Mitigation measure	Classification
2.3	**Streamers**	
2.3.1	Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'.	Abate on site
2.3.2	Ensure that solid streamers rather than fluid-filled streamers are used to avoid leaks.	Avoid
3.	**Key Personnel**	
3.1	• Make provision for the placing of a qualified MMOs on board the seismic vessel. As a minimum, one must be on watch during daylight hours for the pre-shoot observations and when the acoustic source is active. • The duties of the MMO would be to: – Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations; – Record airgun activities, including sound levels, "soft-start" procedures and pre-firing regimes; – Observe and record responses of marine fauna to seismic shooting from optimum vantage points, including seabird, large pelagic fish (e.g. shoaling tuna, sunfish, sharks), turtle, seal and cetacean incidence and behaviour and any mortality or injuries of marine fauna as a result of the seismic survey. Data captured should include species identification, position (latitude/longitude), distance/bearing from the vessel, swimming speed and direction (if applicable) and any obvious changes in behaviour (e.g. startle responses or changes in surfacing/diving frequencies, breathing patterns) as a result of the seismic activities. Both the identification and the behaviour of the animals must be recorded accurately along with current seismic sound levels. Any attraction of predatory seabirds, large pelagic fish or cetaceans (by mass disorientation or stunning of fish as a result of seismic survey activities) and incidents of feeding behaviour among the hydrophone streamers should also be recorded; – Record sightings of any injured or dead marine mammals, large pelagic fish (e.g. sharks), seabirds and sea turtles, regardless of whether the injury or death was caused by the seismic vessel itself. If the injury or death was caused by a collision with the seismic vessel, the date and location (latitude/longitude) of the strike, and the species identification or a description of the animal should be recorded and included as part of the daily report; – Record meteorological conditions at the beginning and end of the observation period, and whenever the weather conditions change significantly; – Request the delay of start-up or temporary termination of the seismic survey or adjusting of seismic shooting, as appropriate. It is important that MMO decisions on the termination of firing are made confidently and expediently, and following dialogue between the observers on duty at the time. A log of all termination decisions must be kept (for inclusion in both daily and "close-out" reports);	Abate on site

No.	Mitigation measure	Classification
	– Use a recording spreadsheet (e.g. JNCC, 2017) in order to record all the above observations and decisions; and – Prepare daily reports of all observations, to be forwarded to the necessary authorities as required, in order to ensure compliance with the mitigation measures.	
3.2	• Make provision for placing of a qualified PAM operator on board the seismic vessel. As a minimum, one must be on "watch" during the pre-shoot observations and when the acoustic source is active. • The duties of the PAM operator would be to: – Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations; – Ensure that the hydrophone cable is optimally placed, deployed and tested for acoustic detections of marine mammals; – Confirm that there is no marine mammal activity within 500 m of the airgun array prior to commencing with the "soft-start" procedures; – Record species identification, position (latitude/longitude), distance and bearing from the vessel and acoustic source, where possible; – Record general environmental conditions; – Record airgun activities, including sound levels, "soft-start" procedures and pre-firing regimes; and – Request the delay of start-up and temporary termination of the seismic survey, as appropriate.	Abate on site
3.3.	Ensure MMOs and PAM operators are briefed on the area-specific sensitivities and on the seismic survey planning (including roles and responsibilities, and lines of communication).	Abate on site
4. Airgun testing		
4.1	Maintain a pre-shoot watch of 60-minutes before any instances of airgun testing. If only a single lowest power airgun is tested, the pre-shoot watch period can be reduced to 30 minutes.	Avoid / Abate on site
4.2	Implement a "soft-start" procedure if testing multiple higher powered airguns. • The "soft-start" should be carried out over a time period proportional to the number of guns being tested and not exceed 20 minutes; airguns should be tested in order of increasing volume. • If testing all airguns at the same time, a 20 minute "soft-start" is required. • If testing a single lowest power airgun a "soft-start" is not required.	Avoid / Abate on site

No.	Mitigation measure	Classification
5. Pre-Start Protocols		
5.1	Implement a dedicated MMO and PAM pre-shoot watch of at least 60 minutes (to accommodate deep-diving species in water depths greater than 200 m).	Avoid / Abate on site
5.2	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if: • during daylight hours it is confirmed: – visually by the MMO during the pre-shoot watch (60 minutes) that there are no cetaceans within 500 m of the seismic source, and – by PAM technology that there are no vocalising cetaceans detected in the 500 m mitigation zone. • during times of poor visibility or darkness it is confirmed by PAM technology that no vocalising cetaceans are present in the 500 m[6] mitigation zone during the pre-shoot watch (60 minutes).	Avoid / Abate on site
5.3	Delay "soft-starts" if cetaceans are observed within the mitigation zone. • A "soft-start" should not begin until 30 minutes after cetaceans depart the 500 m mitigation zone or 30 minutes after they are last seen or acoustically detected by PAM in the mitigation zone.	Avoid / Abate on site
5.4	As noted above for planning, when arriving at the survey area for the first time, survey activities should, as far as possible, only commence during daylight hours with good visibility. However, if this is not possible due to prolonged periods of poor visibility (e.g. thick fog) or unforeseen technical issue which results in a night-time start, the initial acoustic source activation (including gun tests) may only be undertaken if the normal 60-minute PAM pre-watch and "soft-start" procedures have been followed.	Avoid / Abate on site
5.5	Schedule 'soft-starts' so as to minimise, as far as possible, the interval between reaching full power operation and commencing a survey line. The period between the end of the soft start and commencing with a survey line must not exceed 20 minutes. If it does exceed 20 minutes, refer to breaks in firing below.	Abate on site

[6] As noted in the text above, the cumulative effects would only be expected where the animals are known to congregate and do not move away from the area, e.g. from specific coastal areas used as calving sites or from mid-ocean focal sites such as Tripp Seamount. As Tripp Seamount is approximately 50 km to the north of the survey area cumulative effects from multiple pulses would not be expected. Thus, the discussion here focuses on the maximum zone of impact from a single seismic pulse. Although for the most sensitive hearing group (very high frequency cetaceans) the maximum zone of impact from a single seismic pulse is 270 m for PTS onset and 500 m for TTS onset, the recommended mitigation zone is 500 m. This is due to the VHF signal attenuating rapidly and the likelihood of picking up VHF on PAM at a distance of beyond 500 m is very low. Thus, although VHF cetaceans may experience TTS at a distance of up to 500 m at full power, this is unlikely when implementing the soft-start procedure, where the airgun source is under reduced operating pressure conditions, and consequently has lower noise emissions, thereby providing animals the opportunity to leave the area. As such, the zones of impact during the soft start process are predicted to be less than the full-power operation condition. As an example, under a reduced operating pressure of 1 000 PSI, the noise emissions from the airgun array source are approximately 6 dB lower than from the full-power operation, and the resulted zones of impact are estimated to be approximately half of those zones assessed under the full-power operation condition (SLR 2022).

205

No.	Mitigation measure	Classification
6. Line turns		
6.1	If line changes are expected to take longer than 40 minutes: • Terminate airgun firing at the end of the survey line and implement a pre-shoot search (60 minutes) and "soft-start" procedure (20 minutes) when approaching the next survey line. • If line turn is shorter than 80 minutes (i.e. shorter than a 60-minute pre-shoot watch and 20-minute "soft-start" combined), the pre-shoot watch can commence before the end of the previous survey line.	Abate on site
6.2	If line changes are expected to take less than 40 minutes, airgun firing can continue during the line change if: • The power is reduced to 180 cubic inches (or as close as is practically feasible) at standard pressure. Airgun volumes of less than 180 cubic inches can continue to fire at their operational volume and pressure; • The Shot Point Interval (SPI) is increased to provide a longer duration between shots, with the SPI not to exceed 5 minutes; • The power is increased and the SPI is decreased in uniform stages during the final 10 minutes of the line change (or geophone repositioning), prior to data collection re-commencing (i.e. a form of mini soft start); and • Normal MMO and PAM observations continue during this period when reduced power airgun is firing.	Abate on site
7. Shut-Downs		
7.1	Terminate seismic shooting on: • observation and/or detection of cetaceans within the 500 m mitigation zone. • observation of any obvious mortality or injuries to cetaceans when estimated by the MMO to be as a direct result of the survey.	Abate on site
7.2	• For cetaceans, terminate shooting until such time as there has been a 30 minute delay from the time the animal was last sighted within the mitigation zone before the commencement of the normal soft start procedure.	Abate on site
8. Breaks in Airgun Firing		
8.1	If after breaks in firing, airguns can be restarted within 5 minutes, no soft-start is required and firing can recommence at the same power level provided no marine mammals have been observed or detected in the mitigation zone during the break-down period.	Abate on site
8.2	For all breaks in airgun firing of longer than 5 minutes, but less than 20 minutes, implement a "soft-start" of similar duration, assuming there is continuous observation by the MMO and PAM operator during the break.	Abate on site
8.3	For all breaks in firing of 20 minutes or longer, implement a 60-minute pre-shoot watch and 20-minute "soft-start" procedure prior to the survey operation continuing.	Abate on site
8.4	For planned breaks, ensure that there is good communication between the seismic contractor and MMOs and PAM operators in order for all parties to be aware of these breaks and that early commencement of pre-watch periods can be implemented to limit delays.	Abate on site

JC28

No.	Mitigation measure	Classification
9. PAM malfunctions		
9.1	If the PAM system malfunctions or becomes damaged during night-time operations or periods of low visibility, continue operations for 30 minutes without PAM if no marine mammals were detected by PAM in the mitigation zones in the previous 2 hours, while the PAM operator diagnoses the issue. If after 30 minutes the diagnosis indicates that the PAM gear must be repaired to solve the problem, reduce power to 180 cubic inches. Firing of the reduced power gun may continue for 30 minutes while PAM is being repaired, the last 10 minutes of which is a ramp up to full power (mini "soft-start"). If the PAM diagnosis and repair will take longer than 60 minutes, stop surveying until such time as a functional PAM system can be redeployed and tested.	Abate on site
9.2	If the PAM system breaks down during daylight hours, continue operations for 20 minutes without PAM, while the PAM operator diagnoses the issue. If the diagnosis indicates that the PAM gear must be repaired to solve the problem, operations may continue for an additional 2 hours without PAM monitoring as long as: • No marine mammals were detected by PAM in the mitigation zones in the previous 2 hours; • Two MMOs maintain watch at all times during operations when PAM is not operational; and • The time and location in which operations began and stop without an active PAM system is recorded.	Abate on site

Residual Impact Assessment

The potential impacts cannot be eliminated due to the nature of the seismic sound source required during surveying. The proposed mitigation measures, which are essentially designed to keep animals out of the immediate area of impact and thereby reduce the risk of deliberate injury to marine mammals would reduce the intensity of most impacts to medium, and the residual impacts will reduce to low consequence and LOW significance, except for the effects on prey which remains of VERY LOW significance.

4.3.2 Impacts of Seismic Noise on Seals

Source of Impact

The project activities that will result in impacts to seals are listed below.

Project phase	activity
Mobilisation	**N/A**
Operation	**Seismic acquisition/ firing of airguns**
Demobilisation	**N/A**

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition.

Impact Description

The potential impact of seismic survey noise on seals could include physiological injury to individuals, behavioural avoidance of individuals (and subsequent displacement from key habitat), masking of important environmental or biological sounds and indirect effects due to effects on predators or prey. The Cape fur seal that occurs off the West Coast forages over the continental shelf to depths of over 200 m and is thus unlikely to be encountered in the Reconnaissance Permit Area (see Figure 37).

FCDS

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

Seals occur at numerous breeding and non-breeding sites on the mainland, namely at Buchu Twins and Cliff Point near Alexander Bay, Robeiland near Kleinzee, Strandfontein Point, Elephant Rocks, at various emergent reefs around Cape Columbine, Robbesteen near Duynefontein and at Duikerklip and Seal Island on the Cape Peninsula. Seals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles (~220 km) offshore, with bulls ranging further out to sea than females. Seals are therefore unlikely to be encountered in the proposed 3D survey area. Their sensitivity to the proposed seismic operations is considered to be LOW. However, considering the recent mass mortality of seals along much of the South and West Coasts, every precaution should be taken to avoid further stresses to these populations.

Consequence of Impact

Physiological injury or mortality

Underwater behavioural audiograms have been obtained for two species of Otariidae (sea lions and fur seals), but no audiograms have been measured for Cape fur seals. Extrapolation of these audiograms to below 100 Hz would result in hearing thresholds of approximately 140-150 dB re 1 µPa for the California sea lion and well above 150 dB re 1 µPa for the Northern fur seal. The range of greatest sensitivity in fur seals lies between the frequencies of 2-32 kHz (McCauley 1994). Underwater critical ratios have been measured for two northern fur seals and averaged ranged from 19 dB at 4 kHz to 27 dB at 32 kHz. The audiograms available for otariid pinnipeds suggest they are less sensitive to low frequency sounds (<1 kHz) than to higher frequency sounds (>1 kHz). The range of low frequency sounds (30-100 Hz) typical of seismic airgun arrays thus falls below the range of greatest hearing sensitivity in fur seals. This generalisation should, however, be treated with caution as no critical ratios have been measured for Cape fur seals.

Seals produce underwater sounds over a wide frequency range, including low frequency components. Although no measurement of the underwater sounds have been made for the Cape fur seal, such measurements have been made for a con-generic species *Arctocephalus philippii*, which produced narrow-band underwater calls at 150 Hz. Aerial calls of seals range up to 6 Hz, with the dominant energy in the 2-4 kHz band. However, these calls have strong tonal components below 1 kHz, suggesting some low frequency hearing capability and therefore some susceptibility to disturbance from the higher frequency components of seismic airgun sources (Goold & Fish 1998; Madsen *et al.* 2006).

The physiological effects of loud low frequency sounds on seals are not well documented, but include cochlear lesions following rapid rise time explosive blasts (Bohne *et al.* 1985; 1986), TTS following exposure to octave-band noise (frequencies ranged from 100 Hz to 2000 Hz, octave-band exposure levels were approximately 60-75 dB, while noise-exposure periods lasted a total of 20-22 min) (Kastak *et al.* 1999), with recovery to baseline threshold levels within 24 h of noise exposure. Due to the high level of impulsive signal emissions from seismic arrays, seals are predicted to experience a PTS at close proximity to the sound source due to the immediate exposure to individual pulses.

Using measured discomfort and injury thresholds for humans, Greenlaw (1987) modelled the pain threshold for seals and sea lions and speculated that this pain threshold was in the region of 185 - 200 dB re 1 µPa. The impact of physiological injury to seals from seismic noise is deemed to be low as it is assumed that highly mobile creatures such as fur seals would avoid severe sound sources at levels below those at which discomfort occurs. However, noise of moderate intensity and duration may be sufficient to induce TTS under water in pinniped species (Kastak *et al.* 1999), as individuals did not appear to avoid the survey area. Reports of seals swimming within close proximity of firing airguns should thus be interpreted with caution in terms of the impacts on individuals as such individuals may well be experiencing hearing threshold shifts. Their tendency to swim at or near the surface will, however, expose them to reduced sound levels when in close proximity to an operating airgun array.

The Underwater Noise Modelling Study undertaken for the current project (Lewis 2022) identified that for seals (Other Marine Carnivores in water) PTS and TTS were predicted to occur within only 19 m and 24 m of the 3D array, respectively (Table 12). Maximum threshold distance for recoverable injury and TTS from multiple pulses was not reached.

The potential impact of physiological injury to seals as a result of seismic noise is deemed to be of HIGH intensity and would be limited to the survey area (REGIONAL), although injury could extend beyond the survey duration. As seals are known to forage up to 120 nautical miles (~220 km) offshore, the proposed 3D survey area falls well to the west of the foraging range of seals from all of the West Coast colonies. Furthermore, as the duration of the impact would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL), the potential physiological injury is therefore considered to be of MEDIUM consequence.

Behavioural avoidance

Information on the behavioural response of fur seals to seismic exploration noise is lacking (Richardson *et al.* 1995; Gordon *et al.* 2004). Reports of studies conducted with Harbour and Grey seals include initial startle reaction to airgun arrays, and range from partial avoidance of the area close to the vessel (within 150 m) (Harris *et al.* 2001) to fright response (dramatic reduction in heart rate), followed by a clear change in behaviour, with shorter erratic dives, rapid movement away from the noise source and a complete disruption of foraging behaviour (Gordon *et al.* 2004). In most cases, however, individuals quickly reverted back to normal behaviour once the seismic shooting ceased and did not appear to avoid the survey area. Seals seem to show adaptive responses by moving away from airguns and reducing the risk of sustaining hearing damage. Potential for long-term habitat exclusion and foraging disruption over longer periods of exposure (i.e. during full-scale surveys conducted over extended periods) is however a concern.

Cape fur seals generally appear to be relatively tolerant to noise pulses from underwater explosives, which are probably more invasive than the slower rise-time seismic sound pulses. There are also reports of Cape fur seals approaching seismic survey operations and individuals biting hydrophone streamers (CSIR 1998). This may be related to their relative insensitivity to sound below 1 kHz and their tendency to swim at or near the surface, exposing them to reduced sound levels. It has also been suggested that this attraction is a learned response to towed fishing gear being an available food supply.

Although partial avoidance (to less than 250 m) of operating airguns has been recorded for some seal species, Cape fur seals appear to be relatively tolerant to loud noise pulses and, despite an initial startle reaction, individuals quickly reverted back to normal behaviour. The potential impact of seal foraging behaviour changing in response to seismic surveys is thus considered to be of VERY LOW

intensity as they are known to show a tolerance to loud noises. Furthermore, as the duration of the impact would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL), the potential for behavioural avoidance of seals is considered to be of VERY LOW consequence.

Masking of environmental sounds and communication

The use of underwater sounds for environmental interpretation and communication by Cape fur seals is unknown, although masking is likely to be limited by the low duty cycle of seismic pulses (37.5 m interval between consecutive shot-points for 3D). The potential impact of masking of sounds and communication in seals due to seismic surveys is considered to be of VERY LOW intensity as they are known to show a tolerance to loud noises. As the duration of the impact would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL), the potential for masking of sounds is considered to be of VERY LOW consequence.

Indirect effects due to the effects of seismic sounds on prey species

As with other vertebrates, the assessment of indirect effects of seismic surveys on Cape fur seals is limited by the complexity of trophic pathways in the marine environment. The impacts are difficult to determine, and would depend on the diet make-up of the species (and the flexibility of the diet), and the effect of seismic surveys on the diet species. Seals typically forage on small pelagic shoaling fish prey species that occur inshore of the 200 m depth contour or associated with oceanic features such as Child's Bank. Furthermore, the broad ranges of fish prey species (in relation to the avoidance patterns of seismic surveys of such prey species) and the extended foraging ranges of Cape fur seals suggest that indirect impacts due to effects on predators or prey would be of VERY LOW intensity, would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL). The potential for effects of seismic surveys on prey species is thus considered to be of VERY LOW consequence.

Impact Significance

Physiological injury and mortality

The potential impact of seismic noise on physiological injury or mortality of seals, considering their low sensitivity, the very low likelihood of the impact occurring and the medium consequence, is deemed to be of LOW significance.

Behavioural avoidance

The potential impact of seismic noise on behavioural changes in seals, considering their low sensitivity, the very low likelihood of the impact occurring and the very low consequence, is deemed to be of VERY LOW significance.

Masking of Sounds and Communication

The potential impact of seismic noise on the masking of environmental sounds and communications in seals, considering their low sensitivity, the very low likelihood of the impact occurring and the very low consequence, is deemed to be of VERY LOW significance.

Indirect impacts due to effects on predators or prey

JC28

The potential indirect impact of seismic noise on food sources of seals, considering their low sensitivity, the very low likelihood of the impact occurring and the very low consequence, is thus deemed to be of VERY LOW significance.

Identification of Mitigation Measures

In addition to the mitigation measures recommended for cetaceans, the following is recommended for seals:

No	Mitigation measure	Implementation
1	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if during daylight hours it is confirmed visually by the MMO during the pre-shoot watch (60 minutes) that there are no seals within 500 m of the seismic source.	Avoid / Abate on site
2	In the case of fur seals being observed within the mitigation zone, which may occur commonly around the vessel, delay "soft-starts" for at least 10 minutes until it has been confirmed that the mitigation zone is clear of all seal activity. However, if after a period of 10 minutes seals are still observed within 500 m of the airguns, the normal "soft-start" procedure should be allowed to commence for at least a 20-minute duration. Seal activity should be carefully monitored during "soft-starts" to determine if they display any obvious negative responses to the airguns and gear or if there are any signs of injury or mortality as a direct result of the seismic activities.	Avoid / Abate on site
3	Terminate seismic shooting on observation of any obvious mortality or injuries to seals when estimated by the MMO to be as a direct result of the survey.	Abate on site

Residual Impact Assessment

With the implementation of the typical 'soft-start' procedures, the residual impacts of physiological injury and mortality reduce to VERY) LOW significance. All other impacts on seals would all remain NEGLIGIBLE.

4.3.3 Impacts of Seismic Noise on Turtles

Source of Impact

The project activities that will result in impacts to turtles are listed below.

Project phase	Activity
Mobilisation	N/A
Operation	Seismic acquisition/ firing of airguns
Demobilisation	N/A

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition;

Impact Description

The potential effects of seismic surveys on turtles include:

- Physiological injury (including disorientation) or mortality from seismic noise;
- Behavioural avoidance of seismic survey areas;
- Masking of environmental sounds and communication; and
- Indirect impacts due to effects on predators or prey.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

The leatherback and loggerhead turtles that occur in offshore and coastal waters around southern Africa, and likely to be encountered in the Reconnaissance Permit area are considered regionally 'Critically Endangered' and 'Endangered', respectively, in the List of Marine Threatened or Protected Species (TOPS) as part of the NEMBA. Following nesting in December-January, loggerhead turtles migrate back to their foraging grounds along the East and South Coasts (Harris *et al.* 2018). Hatchlings of both species emerge from their nests from mid-January to mid-March with most dispersing south-westward within the Agulhas Current (Le Gouvello *et al.* 2020). The Agulhas Current migration corridor will therefore be very active with migrating sea turtles between January and April (Harris *et al.* 2018), some of which may be distributed along the West Coast through mass transport of Agulhas

Current water into the southeast Atlantic by warm core rings (Figure 47). Despite their extensive distributions and feeding ranges, the numbers of adult and neonate turtles encountered in the Reconnaissance Permit Area may therefore be seasonally high, particularly in the Child's Bank and Orange Shelf Edge MPAs, and the Orange Seamount and Canyon Complex transboundary EBSA, which may be frequented by leatherbacks on their migrations. Consequently, the sensitivity of turtles to seismic noise is considered to be HIGH, particularly neonates and juveniles as they are unable to actively avoid seismic sounds and consequently are more susceptible to seismic noise.

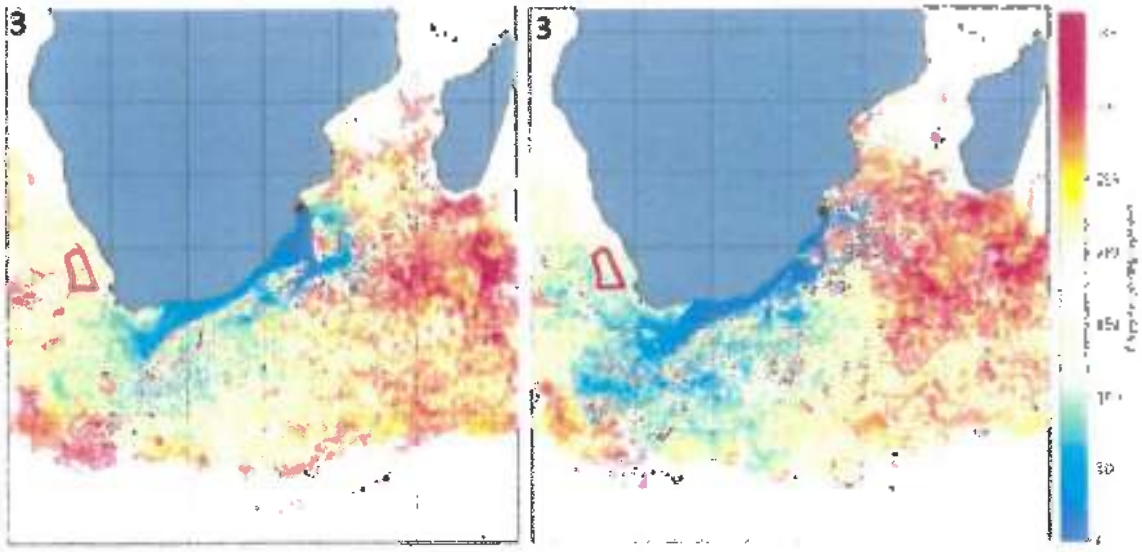

Figure 47: Virtual hatchling trajectories for loggerhead (left) and leatherback (right) turtles after 365 days (48 hr @0.15 m/s then no swim) in relation to Reconnaissance Permit Area (red polygon) (adapted from Le Gouvello *et al.* 2020).

Consequence of Impact

Available data on marine turtle hearing is limited, but suggest highest auditory sensitivity at frequencies of 250 - 700 Hz, and some sensitivity to frequencies at least as low as 60 Hz (Ridgway *et al.* 1969; Wever *et al.* 1978, in McCauley 1994; O'Hara & Wilcox, 1990; Moein-Bartol *et al.* 1999). More recent studies using electrophysiological and behavioural techniques have found that turtles can detect frequencies between 50 Hz and 1 600 Hz (Bartol & Ketten 2006; Lavender *et al.* 2014; Martin *et al.* 2012; Dow-Piniak *et al.* 2012a, 2012b; Papale *et al.* 2020), indicating that their hearing ranges overlap with the peak amplitude, low frequency sound emitted by seismic airguns (10-500 Hz; DeRuiter & Larbi Doukara 2012; Parente *et al.* 2006). The overlap of this hearing sensitivity with the higher frequencies produced by airguns, suggest that turtles may be considerably affected by seismic noise (see review by Nelms *et al.* 2016), although what effect this may have on their fitness or survival is not known.

Physiological injury (including disorientation) or mortality

Due to a lack of research, it is not known what levels of sound exposure (or frequencies) would cause permanent or temporary hearing loss or what effect this may have on the fitness or survival of turtles (DeRuiter & Larbi Doukara 2012), although Eckert *et al.* (1998) assumed physiological effects at levels of 190 dB re 1 µPa ref 1 m, while Popper *et al.* (2014) have predicted that mortality or potential

mortal injury will occur at peak sound pressure levels of over 207 dB re 1 µPa. Evidence, however, suggests that turtles only detect airguns at close range (<10 m) or are not sufficiently mobile to move away from approaching airgun arrays (particularly if basking). Initiation of a sound source at full power in the immediate vicinity of a diving, swimming or basking turtle would thus be expected to result in physiological injury. This applies particularly to hatchlings and juveniles as they are unable to avoid seismic sounds whilst being transported in the ocean currents, and consequently are more susceptible to seismic noise. For the first few months following emergence, hatchlings are reported to spend most of their time in the upper 5 m of the water column (Salmon *et al.* 2004; Howell *et al.* 2010; Mansfield *et al.* 2014). Juveniles in contract appear to spend most of their time diving to depths, spending only 43% of their time at the surface during the day and 29% of the time at the surface during the night (Freitas *et al.* 2018, 2019). Both hatchlings and juveniles would therefore be particularly susceptible to airguns at close range.

If subjected to seismic sounds at close range, temporary or permanent hearing impairment may result, but it is unlikely to cause death or life-threatening injury. As with other large mobile marine vertebrates, it is assumed that adult turtles will avoid seismic noise at levels/distances where the noise is a discomfort. Juvenile turtles may be unable to avoid seismic sounds in the open ocean, and consequently may be more susceptible to seismic noise.

The noise exposure criteria for turtles were established in 2004 under the ANSI-Accredited Standards Committee S3/SC 1: Animal Bioacoustics sponsored by the Acoustical Society of America. The criteria for seismic airguns were subsequently provided by Popper *et al.* (2014) (Table 13).

Table 13: Noise exposure criteria in turtles for seismic airguns (after Popper *et al.* 2014).

Animal	Zones of impact – maximum horizontal distances from source to impact threshold levels (from single 3D pulses)		Zones of impact – maximum horizontal perpendicular distances from assessed 3D survey lines to cumulative impact threshold levels	
	Injury (PTS) onset Pk SPL re 1 µPa	TTS onset Pk SPL	Injury (PTS) onset Weighted SEL_{24h} re 1 $\mu Pa^2 \cdot s$	TTS onset Weighted SEL_{24h} re 1 $\mu Pa^2 \cdot s$
Sea turtles	232 m	226 m	204 m	189 m

Using the peak sound pressure level of 232 dB re 1 µPa, the Underwater Noise Modelling Study undertaken for the current project (SLR 2022) identified that the maximum horizontal distance from the seismic source to impact threshold levels leading to mortality or potential mortal injury in turtles was 19 m and therefore highly localised at any one time. The maximum horizontal distance from the seismic source to impact threshold levels leading to recoverable injury (TTS) was 24 m. The zones of cumulative impact from multiple pulses (i.e. the maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels), was estimated as 10 m for mortality and potential mortal injury. Maximum threshold distances for recoverable injury and TTS from multiple pulses was estimated at 500 m. It must be kept in mind that the cumulative zones of impact are

JL28

conservative, as any turtles likely to be encountered in the Orange Basin area are the highly migratory, and are likely to have moved considerable distances over the cumulative 24-hr period.

As the breeding areas for Leatherback turtles in Gabon occur over 1 500 km to north of the proposed 3D survey area, and on the northeast coast of South Africa, turtles encountered during the survey are likely to be adults migrating to foraging grounds, and dispersing neonates and juveniles. Although turtles have extensive distributions and feeding ranges, the number of turtles encountered in the survey area is expected to be low. Despite their low numbers in the survey area, the intensity of potential physiological injury would be thus rated as **HIGH**. However, the duration of the impact on the population would be limited to the **IMMEDIATE-TERM** (1.5 months) and be restricted to the survey area (**REGIONAL**). The potential physiological injury or mortality of turtles is considered to be of **MEDIUM consequence**.

Behavioural avoidance

Behavioural changes in response to anthropogenic sounds have been reported for some sea turtles. Controlled exposure experiments on captive turtles found an increase in swim speed and erratic behaviour indicative of avoidance, at received airgun sound levels of 160 - 176 dB re 1 µPa (O'Hara & Wilcox 1990; Eckert *et al.* 1998; McCauley *et al.* 2000). Sounds of frequency of 250 and 500 Hz resulted in a startle response from a loggerhead turtle (Lenhardt *et al.* 1983; Lenhardt 1994), and avoidance by 30 m of operating airguns where the received level would have been in the order of 175 - 176 dB re 1 µPa (O'Hara & Wilcox 1990). McCauley (1994), however, pointed out that these results may have been influenced by echo associated with the shallow environment in which the test was undertaken.

Further trials carried out on caged loggerhead and green turtles indicated that significant avoidance response occurred at received levels ranging between 172 and 176 dB re 1 µPa at 24 m, and repeated trails several days later suggest either temporary reduction in hearing capability or habituation with repeated exposure. Hearing however returned after two weeks (Moein *et al.* 1994; Lenhardt *et al.* 1994; McCauley *et al.* 2000). McCauley *et al.* (2000) reported that above levels of 166 dB re 1 µPa turtles increased their swimming activity compared to periods when airguns were inactive. Above 175 dB re 1 µPa turtle behaviour became more erratic possibly reflecting an agitated behavioural state at which unrestrained turtles would show avoidance response by fleeing an operating sound source. These would correspond to distances of 2 km and 1 km from a seismic vessel operating in 100 - 120 m of water, respectively. The behavioural threshold of 166 dB re 1 µPa for sea turtles as established by McCauley *et al.* (2000) was subsequently adopted by the National Marine Fisheries Services (NMFS) (NSF 2011).

Observations of marine turtles during a ten-month seismic survey in deep water (1 000-3 000 m) off Angola found that turtle sighting rate during guns-off (0.43 turtles/h) was double that of full-array seismic activity (0.20/h) (Weir 2007). These results should be treated with caution, however, since a large proportion of the sightings occurred during unusually calm conditions and during peak diurnal abundance of turtles when the airguns were inactive (Weir 2007). In contrast, Parente *et al.* (2006), working off Brazil found no significant differences in turtle sightings with airgun state. It is possible that during deep water surveys turtles only detect airguns at close range or are not sufficiently mobile to move away from approaching airgun arrays (particularly if basking for metabolic purposes when they may be slow to react) (Weir 2007). This is in marked contrast to previous assessments that assumed that the impact of seismic noise on behaviour of adult turtles in the open ocean environment is of low significance given the mobility of the animals (CSIR 1998; CCA & CMS 2001). In the study by

JCDS

Weir (2007) a confident assessment of turtle behaviour in relation to seismic status was hindered, however, by the apparent reaction of individual animals to the survey vessel and towed equipment rather than specifically to airgun sound. As these reactions occurred at close range (usually <10 m) to approaching objects, they appeared to be based principally on visual detection.

Information on how individuals might respond behaviourally to seismic sounds thus remains inconclusive and may be species specific (Pirniak *et al.* 2012, 2016; van der Wal *et al.* 2016). Acoustic disturbance could potentially lead to exclusion from key habitats, interruption of breeding, foraging or basking behaviours, or may incite responses which may compromise the turtle's energy budgets (e.g. changes to foraging duration, swim speed, dive depth and duration, and restricting access to the surface to breath) (DeRuiter & Larbi Doukara 2012). Such changes could lead to a reduction in individual fitness (through changes to reproductive outputs or foraging rates), potentially causing detrimental effects at a population level.

Using the RMS SPL criteria of 175 dB re 1 µPa, the Underwater Noise Modelling Study undertaken for the current project (SLR 2022) identified that the maximum threshold distance for behavioural disturbance for turtles caused by the immediate exposure to individual pulses was predicted to be within 1 300 m from the 3D array. Turtles can therefore hear seismic sounds at a considerable distance and may respond by altering their swimming/basking behaviour or alter their migration route. However, as the number of turtles encountered during the proposed 3D survey is expected to be low, the impact of seismic sounds on turtle behaviour would be of LOW intensity, and would persist only for the duration of the survey (IMMEDIATE - 1.5 months), and be restricted to the survey area (REGIONAL). The impact of seismic noise on turtle behaviour is thus deemed to be of VERY LOW consequence.

Masking of environmental sounds and communication

Breeding adults of sea turtles undertake large migrations between distant foraging areas and their nesting sites (within the summer months October to March, with peak nesting during December and January). Although Lenhardt *et al.* (1983) speculated that turtles may use acoustic cues for navigation during migrations, information on turtle communication is lacking. The effect of seismic noise in masking environmental cues such as surf noise (150-500 Hz), which overlaps the frequencies of optimal hearing in turtles (McCauley 1994), is unknown and speculative.

As the breeding areas for Leatherback turtles occur over 1 500 km to north of the survey area in Gabon, and on the north-east coast of South Africa, turtles encountered during the survey are likely to be migrating vagrants. Their low abundance in the survey area would suggest that the impact (should it occur) would be of VERY LOW intensity. As the impact would persist only for the duration of the survey (IMMEDIATE - 1.5 months), and be restricted to the survey area (REGIONAL), the impact is deemed to be of VERY LOW consequence.

Indirect impacts due to effects on prey

As with other vertebrates, the assessment of indirect effects of seismic surveys on turtles is limited by the complexity of trophic pathways in the marine environment. The leatherback turtles eat pelagic prey, primarily jellyfish. The low numbers and the broad ranges of potential prey species and extensive ranges over which most turtles feed suggest that indirect impacts would be of VERY LOW intensity, persisting only for the duration of the survey (IMMEDIATE - 1.5 months), and restricted to the survey area (REGIONAL). The impact would therefore be of VERY LOW consequence.

3229

Impact Significance

Physiological injury and mortality

The potential impact of seismic noise on physiological injury or mortality of turtles, considering their high sensitivity and medium consequence, is deemed to be of **MEDIUM** significance. In the case of hatchlings and juveniles, the impact can be considered of **MEDIUM** significance due to their high sensitivity and the potentially high intensity of the impact.

Behavioural avoidance

The potential impact of seismic noise on behavioural changes in turtles, considering their medium sensitivity, the medium probability of the impact occurring and the very low consequence, is deemed to be of **VERY LOW** significance.

Masking of Sounds and Communication

The potential impact of seismic noise on the masking of environmental sounds and communications in turtles, considering their medium sensitivity, the medium probability of the impact occurring and the very low consequence, is deemed to be of **VERY LOW** significance.

Indirect impacts due to effects on predators or prey

The potential indirect impact of seismic noise on food sources of turtles, considering their medium sensitivity, the very low likelihood of the impact occurring and the very low consequence, is thus deemed to be of **VERY LOW** significance.

Identification of Mitigation Measures

Van der Wal *et al.* (2016) report on innovative measures for mitigating potential impacts on turtles during seismic surveys. They point out that the standard mitigation measures developed for marine mammals ("soft-starts", MMOs) may be less effective for sea turtles as these have a shorter surface presence per unit time and a much lower surfacing profile than do marine mammals. This makes turtles increasingly difficult to detect by MMOs in sea states greater than Beaufort 2. The following mitigation measures are recommended for sea turtles:

No.	Mitigation measure	Classification
1	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if during daylight hours it is confirmed visually by the MMO during the pre-shoot watch (60 minutes) that there are no turtles within 500 m of the seismic source.	Avoid / Abate on site
2	In the case of turtles being observed within the mitigation zone, delay the "soft-start" until animals are outside the 500 m mitigation zone.	Avoid / Abate on site
3	Terminate seismic shooting on: – Observation of turtles within the 500 m mitigation zone. – observation of any obvious mortality or injuries to turtles when estimated by the MMO to be as a direct result of the survey. For turtles, terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required).	Abate on site
4	Avoid surveying within 100 m of critical foraging habitats (e.g. seamounts or convergence zones)	Avoid

8128

Residual Impact Assessment

With the implementation of the mitigation measures above, the residual impact on potential physiological injury would reduce to LOW. The other impacts would remain of VERY LOW significance.

4.3.4 Impacts of Seismic Noise on Seabirds

Source of Impact

The project activities that will result in impacts to seabirds are listed below.

[illegible]	[illegible]
Mobilisation	N/A
Operation	Seismic acquisition/ firing of airguns
Demobilisation	N/A

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition.

Impact Description

Potential impacts of seismic pulses to diving birds could include physiological injury, behavioural avoidance of seismic survey areas and indirect impacts due to effects on prey. The seabird species

are all highly mobile and would be expected to flee from approaching seismic noise sources at distances well beyond those that could cause physiological injury, but initiation of a sound source at full power in the immediate vicinity of diving seabirds could result in injury or mortality where feeding behaviour override a flight response to seismic survey sounds. The potential for physiological injury or behavioural avoidance in non-diving seabird species, being above the water and thus not coming in direct contact with the seismic pulses, is considered NEGLIGIBLE and will not be discussed further here.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

Among the marine avifauna occurring along the West Coast of South Africa, it is only the diving birds, or birds which rest on the water surface, that may be affected by the underwater noise of seismic surveys. The African Penguin (*Spheniscus demersus*), which is flightless and occurs along the southwestern Cape coastline, would be particularly susceptible to impacts from underwater seismic noise. Similarly, Cape Gannets dive for their pelagic prey and would be susceptible to seismic noise. Penguins from the Robben Island colony have been tracked feeding up to 70 km offshore of the island (Campbell 2016), and Cape Gannets are known to forage within 200 km offshore (Dundee 2006; Ludynia 2007; Grémillet *et al.* 2008) and both species therefore unlikely to be encountered in the proposed 3D survey area. Both species are considered 'Endangered' on a national and global scale. Of the pelagic seabirds likely to occur in the offshore regions characterising the Orange Basin, many are considered regionally 'Vulnerable' (e.g. White-chinned Petrel), 'Endangered' (e.g. Black-browed Albatross, Atlantic Yellow-nosed Albatross, Subantarctic Skua) and 'Critically Endangered' (Leach's Storm Petrel). Pelagic seabirds spend a significant proportion of their lives on the open ocean diving or skimming the surface for food and resting on the water surface, returning to Southern Ocean islands only to breed. Tripp Seamount is located approximately 50 km to the north of the proposed 3D survey area, which is an important feature because it attracts an abundance of marine life and is a productive fishing ground. Despite their extensive distributions and feeding ranges, the proposed survey area overlaps with core usage areas for Yellow-nosed Albatross and Wandering Albatross (see Figure 27). The numbers of individuals encountered during the survey may thus not be insignificant, particularly in the vicinity of the Child's Bank and Orange Shelf Edge MPAs and associated with Tripp Seamount. Consequently, the sensitivity for both coastal and pelagic seabirds is considered to be MEDIUM.

Consequence of Impact

Birds are well known for their acoustic communication and hearing abilities, but psychophysical or behavioural data on how birds hear or react to sound underwater is currently lacking (Dooling 2012).

Recent studies on the in-air and underwater hearing in the great cormorant (*Phalacrocorax carbo sinensis*) identified that their greatest sensitivity was at 2 kHz, with an underwater hearing threshold of between 71 - 79 dB re 1 µPa rms (Johansen *et al.* 2016; Hansen *et al.* 2017; Larsen *et al.* 2020) suggesting that the species is better at hearing underwater than in air, with hearing thresholds in the frequency band 1-4 kHz comparable to those of seals and toothed whales. This opens up the possibility of cormorants and other aquatic birds having special adaptations for underwater hearing

and making use of underwater acoustic cues from conspecifics, their surroundings, as well as prey and predators.

In African Penguins the best hearing is in the 600 Hz to 4 kHz range with the upper limit of hearing at 15 kHz and the lower limit at 100 Hz (Wever *et al.* 1969). Compared to other birds (Necker 2000), African Penguins were considered to be relatively insensitive to sounds both in terms of frequency and intensity (Wever *et al.* 1969). No critical ratios have, however, been measured. Principal energy of vocalisation of African penguins was found at <2 kHz, although some energy was measured at up to 6 kHz (Wever *et al.* 1969). Penguins are known to respond to underwater vocalisations of predators (Frost *et al.* 1975). Recently underwater vocalisations have been recorded in King, Gentoo and Macaroni penguins with a frequency of maximum amplitude averaging 998 Hz, 1097 Hz and 680 Hz, respectively (Thiebault *et al.* 2019).

Physiological injury

The continuous nature of the intermittent seismic survey pulses suggest that diving birds would hear the sound sources at distances where levels would not induce mortality or injury, and consequently be able to flee an approaching sound source. Available evidence, although scant, therefore suggests that most diving seabirds would be able to hear seismic sounds at considerable distances, and consequently be able to flee an approaching sound source at distances where levels would not induce injury or mortality. The potential for physiological injury to seabirds from seismic surveys in the open ocean is thus deemed to be low (see also Stemp 1985, in Tumpenny & Nedwell 1994), particularly given the extensive feeding range of the potentially affected seabird species.

Of the plunge diving species that occur along the West Coast, the Cape Gannet regularly feeds as far offshore as 100 km, the rest foraging in nearshore areas up to 40 km from the coast, although Cape Cormorants have been reported up to 80 km from their colonies. The nearest Cape Gannet nesting grounds are at Lambert's Bay and Malgas Island, 300 km and 285 km inshore and to the southeast of the eastern boundary of the Reconnaissance Permit area, respectively. The nearest African Penguin nesting sites are similarly at Lambert's Bay, on the Saldanha Bay Islands and at Robben Island. This species forages at sea with most birds being found within 20 km of the coast, although individuals have been recorded as far as 70 km offshore. As the survey area is situated well beyond the foraging ranges of these coastal species, encounters with both Cape Gannets and African penguins are unlikely during 3D seismic acquisition in offshore waters. In the offshore environment, pelagic seabirds that dive for their prey may, however, be encountered, particularly in the portions of the survey area closest to Tripp Seamount.

Should an encounter with diving pelagic seabirds occur, the potential physiological impact on individual pelagic and coastal diving birds would be of HIGH intensity, but as the likelihood of encountering large numbers of diving seabirds is low, due to their extensive distributions and feeding ranges the intensity is considered MEDIUM. Furthermore, the duration of the impact on the population would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL). The potential for physiological injury is therefore considered to be of LOW consequence.

Behavioural avoidance

Diving birds would be expected to hear seismic sounds at considerable distances as they have good hearing at low frequencies (which coincide with seismic shots). Response distances are speculative, however, as no empirical evidence is available. Evidence from studies at Bird and St Croix Islands in Algoa Bay, South Africa on the behavioural response of African Penguins to seismic operations within

JL25

100 km of their colonies found that they showed a strong avoidance of their preferred foraging areas during seismic activities. Birds were reported to forage significantly further from the survey vessel when in operation, while increasing their overall foraging effort. Although maximum foraging distance to the colony increased during seismic activity, this increase was not significant relative to outside of seismic activity, with mean maximum distances in the order of 28 km. The birds reverted to normal foraging behaviour when the seismic operations ceased (Pichegru *et al.* 2017). For penguins who spend considerable time underwater while hunting, the impact zone for behavioural disturbance may, however, be larger than for plunge diving species that undertake short dives only before returning to the sea surface.

Due to the extensive distribution and feeding ranges of pelagic seabirds, the impact for pelagic seabirds would thus be of LOW intensity within the survey area (REGIONAL) over the duration of the survey period (IMMEDIATE - 1.5 months). For African Penguins and Cape Gannets, the impact for would thus be of HIGH intensity, but as the likelihood of encountering large numbers in offshore areas is low, the intensity is considered MEDIUM. Similarly, for pelagic seabirds the impact would be of HIGH intensity, but due to their extensive distributions and feeding ranges, the likelihood of encountering significant numbers is low, and the intensity is therefore considered MEDIUM. The duration of the impact on the population would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL). The behavioural avoidance of feeding areas by diving seabirds is thus considered to be of VERY LOW consequence and for coastal diving seabirds to be of LOW consequence.

Indirect impacts due to effects on prey

As with other vertebrates, the assessment of indirect effects of seismic surveys on diving seabirds is limited by the complexity of trophic pathways in the marine environment. The impacts are difficult to determine, and would depend on the diet make-up of the bird species concerned and the effect of seismic surveys on the diet species. With few exceptions, most plunge-diving birds forage on small shoaling fish prey species that typically occur relatively close to the shore (<200 m depth) or associated with oceanic features such as the Child's Bank and Tripp Seamount. Cape Gannets vocalise regularly while at sea to maintain group cohesion and avoid collision, and rely on visual observation of other (diving) gannets as a cue to find food (Thiebault *et al.* 2014, 2016), while African Penguins have been reported to hunt cooperatively larger groups (25 165) to corral shoaling fish to the surface, where they subsequently become more accessible to other avian predators such as Cape gannets and cormorants (McInnes *et al.* 2017).

Other than the report of Pichgru *et al.* (2017) for penguins at the Algoa Bay Islands no information is available on the feeding success of seabirds in association with seismic survey noise. Although seismic surveys have been reported to affect fish catches up to 30 km from the sound source, with effects persisting for a duration of up to 10 days, for the current project relatively low behavioural risks are expected for fish species at far-field distances (1 000s of metres) (Lewis 2022). This could have implications for plunge-diving seabirds such as African Penguins that forage in restricted areas within a given radius of their breeding sites. Similarly, pelagic seabirds that feed around seamounts may also be affected. As the survey area is located beyond the foraging range of African penguins and Cape gannets, and Tripp Seamount is located ~50 km north of the proposed survey area, seismic effects on the prey species of coastal seabirds, or pelagic seabirds that feed around seamounts is not expected. The impact on potential food sources for pelagic and coastal diving seabirds would thus be of VERY LOW intensity within the survey area (REGIONAL) over the duration of the survey period

(IMMEDIATE - 1.5 months). The broad ranges of potential fish prey species (in relation to potential avoidance patterns of seismic surveys of such prey species) and extensive ranges over which most seabirds feed suggest that indirect impacts would be of VERY LOW consequence.

The impact on potential food sources for pelagic seabirds would thus be of VERY LOW intensity within the survey area (LOCAL) over the duration of the survey period (1.5 months). The broad ranges of potential fish prey species (in relation to potential avoidance patterns of seismic surveys of such prey species) and extensive ranges over which most seabirds feed suggest that indirect impacts would be of VERY LOW consequence.

Impact Significance

Physiological injury and mortality

The potential impact of seismic noise on physiological injury or mortality of pelagic seabirds, considering their medium sensitivity, the medium likelihood of the impact occurring and low consequence, is deemed to be of LOW significance.

Behavioural avoidance

The potential impact of seismic noise on behavioural changes in pelagic seabirds, considering their medium sensitivity the medium likelihood of the impact occurring and very low to low consequence, is deemed to be of VERY LOW to LOW significance.

Indirect impacts due to effects on predators or prey

The potential indirect impact of seismic noise on food sources for pelagic seabirds, considering their medium sensitivity, the very low likelihood of the impact occurring and the very low consequence, is thus deemed to be of VERY LOW significance.

Identification of Mitigation Measures

As the proposed survey area is located far offshore, it is not deemed necessary to implement mitigation measures to avoid the pre- and postmoult periods for African penguins. In addition to the mitigation measures recommended for cetaceans, the following is recommended for feeding aggregations of diving seabirds:

No.	Mitigation measure	Classification
1	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if during daylight hours it is confirmed visually by the MMO during the pre-shoot watch (60 minutes) that there are no penguins or feeding aggregations of diving seabirds within 500 m of the seismic source.	Avoid / Abate on site
2	In the case of penguins or feeding aggregations of diving seabirds being observed within the mitigation zone, delay the 'soft-start' until animals are outside the 500 m mitigation zone.	Avoid / Abate on site
3	Terminate seismic shooting on observation of penguins and feeding aggregations of diving seabirds within the 500 m mitigation zone. For penguins and feeding aggregations of diving seabirds, terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required).	Abate on site

Residual Impact Assessment

With the implementation of the mitigation measures above, the residual impact on potential physiological injury or behavioural avoidance by seabirds, masking of sounds and indirect impacts on food sources would remain VERY LOW.

4.3.5 Impacts of Seismic Noise on Fish

Source of Impact

The project activities that will result in impacts to fish are listed below.

Project phase	Activity
Mobilisation	N/A
Operation	Seismic acquisition/ firing of airguns
Demobilisation	N/A

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition.

Impact Description

Fish hearing has been reviewed by numerous authors including Popper and Fay (1973), Hawkins (1973), Atema *et al.* (1988), Hawkins & Popper (2018) and Slabbekoorn *et al.* (2019) (amongst others). Fish have two different systems to detect sounds namely 1) the ear (and the otolith organ of their inner ear) that is sensitive to sound pressure and 2) the lateral line organ that is sensitive to particle motion. Certain species utilise separate inner ear and lateral line mechanisms for detecting sound; each system having its own hearing threshold (Tavolga & Wodinsky 1963), and it has been suggested that fish can shift from particle velocity sensitivity to pressure sensitivity as frequency increases (Cahn *et al.* 1970, in Turl 1993). More recently, Popper & Hawkins (2018) determined that most fish (and all elasmobranchs) primarily detect particle motion.

In fish, the proximity of the swim-bladder to the inner ear is an important component in the hearing as it acts as the pressure receiver and vibrates in phase with the sound wave. Vibrations of the otoliths, however, result from both the particle velocity component of the sound as well as stimulus from the swim-bladder. The resonant frequency of the swim-bladder is important in the assessment of impacts of sounds as species with swim-bladders of a resonant frequency similar to the sound frequency would be expected to be most susceptible to injury. Although the higher frequency energy of received seismic impulses needs to be taken into consideration, the low frequency sounds of seismic surveys would be most damaging to swim-bladders of larger fish. The lateral line is sensitive to low frequency (between 20 and 500 Hz) stimuli through the particle velocity component of sound and would thus be sensitive to the low frequencies of airguns, which most energy at 20-150 Hz.

The sound waves produced during seismic surveys are low frequency, with most energy at 20-150 Hz (although significant contributions may extend up to 500 Hz) (Hirst & Rodhouse 2000), and overlap with the range at which fish hear well (Dalen & Naested 2008). A review of the available literature suggests that potential impacts of seismic pulses to fish (including sharks) species could include physiological injury and mortality, behavioural avoidance of seismic survey areas, reduced reproductive success and spawning, masking of environmental sounds and communication, and indirect impacts due to effects on predators or prey (Popper & Hawkins 2018).

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

Most species of fish and elasmobranchs are able to detect sounds from well below 50 Hz (some as low as 10 or 15 Hz) to upward of 500 - 1 000 Hz (Popper & Fay 1999; Popper 2003; Popper *et al.* 2003), with hearing specialists able to detect sounds to 4 000 Hz (Ladich & Fay 2013). Consequently, fish can detect sounds within the frequency range of most widely occurring anthropogenic noises. Within the frequency range of 100 - 1 000 Hz at which most fish hear best, hearing thresholds vary considerably (50 and 110 dB re 1 µPa). They are able to discriminate between sounds, determine the direction of a sound, and detect biologically relevant sounds in the presence of noise (Popper & Hawkins 2019). In addition, some clupeid fish can detect ultrasonic sounds to over 200 kHz (Popper & Fay 1999; Mann *et al.* 2001; Popper *et al.* 2004). Fish that possess a coupling between the ear and swim-bladder have probably the best hearing of fish species (McCauley 1994). Consequently, there is a wide range of susceptibility among fish to seismic sounds, with those with a swim-bladder will be more susceptible to anthropogenic sounds than those without this organ (Popper & Hawkins 2019). Such species may suffer physiological injury or severe hearing damage and adverse effect may intensify and last for a considerable time after the termination of the sound source. Fish without swim bladders include jawless fishes, elasmobranchs (sharks, skates and rays), some flatfishes, some gobies, and some tuna and other pelagic and deep-sea species (Popper *et al.* 2014). As hearing thresholds differ greatly among species, the impacts of seismic sounds are therefore species specific.

The greatest risk of physiological injury from seismic sound sources is for species that establish home ranges on shallow- or deep-water reefs or congregate in areas to spawn or feed, and those displaying an instinctive alarm response to hide on the seabed or in the reef rather than flee. Such species would be associated with the seabed (at >1 500 m) or with Child's Bank or Tripp Seamount. The fish most likely to be encountered on the shelf, beyond the shelf break and in the offshore waters of the proposed 3D survey area are the large migratory pelagic species. In many of the large pelagic species, the swim-bladders are either underdeveloped or absent, and the risk of physiological injury through damage of this organ is therefore lower. However, many of the large pelagic fish and shark species likely to occur in the offshore regions characterising the Orange Basin are considered globally 'Vulnerable' (e.g. bigeye tuna, blue marlin, Oceanic Whitetip shark, dusky shark, great white shark, longfin mako), 'Endangered' (e.g. shortfin mako, whale shark) and 'Critically Endangered' (Southern bluefin tuna). However, the numbers of individuals encountered during the survey are likely to be low, even when these species are *en route* to or from recognised feeding grounds associated with Tripp Seamount or Child's Bank where greater concentrations of pelagic fish can be expected. The sensitivity of fish to seismic noise is considered to be HIGH sensitivity.

Consequence of Impact

The physiological effects of seismic sounds from airgun arrays will mainly affect the younger life stages of fish such as eggs, larvae and fry, many of which form a component of the meroplankton and thus have limited ability to escape from their original areas in the event of various influences. These have been dealt with under section 4.3.7 below.

Physiological injury and mortality

Studies have shown that fish can be exposed directly to the sound of seismic survey without lethal effects, outside of a very localised range of physiological effects. Exposure of fishes to very high intensity low and mid-frequency sonars resulted in no mortality (Halvorsen *et al.* 2013; Popper *et al.* 2007), nor did exposure to seismic airguns (Popper *et al.* 2005; Popper *et al.* 2016). Physiological effects of impulsive airgun sounds on fish species include swim-bladder damage (Falk & Lawrence 1973), transient stunning (Hastings 1990, in Turnpenney & Nedwell 1994), short-term biochemical variations in different tissues typical of primary and secondary stress response (Santulli *et al.* 1999; Smith *et al.* 2004; Nedelec *et al.* 2015; Sierra-Flores *et al.* 2015), and temporary hearing loss (TTS) due to destruction of the hair cells in the hearing maculae (Enger 1981; Lombarte *et al.* 1993; Hastings *et al.* 1996; McCauley *et al.* 2000; Scholik & Yan 2001, 2002; McCauley *et al.* 2003; Popper *et al.* 2005; Smith *et al.* 2006; Smith & Monroe 2016) and haemorrhaging, eye damage and blindness (Hirst & Rodhouse 2000; Halvorsen *et al.* 2012). Although TTS has been demonstrated in a number of species from a diverse array of sounds (Smith & Monroe 2016), in all cases it only occurred after multiple exposures to intense sounds (<190 dB re 1 µPa rms) or as a result of long-term exposure to less intense sounds (Popper & Hawkins 2019).

Physical damage may lead to delayed mortality as reduced fitness is associated with higher vulnerability to predators and decreased ability to locate prey (Hirst & Rodhouse 2000; McCauley *et al.* 2003; Popper *et al.* 2005). Reduced heart rate (bradycardia) in response to the particle motion component of the sound from the airgun, indicative of an initial flight response has also been reported (Davidsen *et al.* 2019). Popper (2008) concludes that as the vast majority of fish exposed to seismic sounds will in all likelihood be some distance from the source, where the sound level has attenuated considerably, only a very small number of animals in a large population will ever be directly killed or damaged by sounds from seismic airgun arrays. Consequently, direct physical damage from exposure to high level sound from airguns was not considered an issue that required special mitigation (Gausland 2003).

The noise exposure criteria for fish were established in 2004 under the ANSI-Accredited Standards Committee S3/SC 1: Animal Bioacoustics sponsored by the Acoustical Society of America. The exposure criteria for seismic airguns were subsequently provided by Popper *et al.* (2014) (Table 14).

Child's Bank and Tripp Seamount lie ~30 km east and ~25 km north of the proposed 3D survey area, and any demersal species associated with these important fishing banks would receive the seismic noise within the far-field range, and outside of distances at which physiological injury or avoidance would be expected. Impacts on demersal species are thus deemed of VERY LOW intensity across the survey area (REGIONAL) and for the survey duration (IMMEDIATE) and are considered to be of VERY LOW consequence.

Table 14: Noise exposure criteria in fish for seismic airguns (after Popper *et al.* 2014).

Type of animal	Mortality and potential mortal injury	Impairment			Behaviour
		Recovery injury	TTS	Masking	
Fish: no swim bladder (particle motion detection)	>219 dB SEL_{24hr} or >213 dB Pk SPL	>216 dB SEL_{24hr} or >213 dB Pk SPL	>>186 dB SEL_{24hr}	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder is not involved in hearing (particle motion detection)	210 dB SEL_{24hr} or >207 dB Pk SPL	203 dB SEL_{24hr} or >207 dB Pk SPL	>>186 dB SEL_{24hr}	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder involved in hearing (primarily pressure detection)	207 dB SEL_{24hr} or >207 dB Pk SPL	203 dB SEL_{24hr} or >207 dB Pk SPL	186 dB SEL_{24hr}	(N) Low (I) Low (F) Moderate	(N) High (I) High (F) Moderate
Fish eggs and fish larvae	>210 dB SEL_{24hr} or >207 dB Pk SPL	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low

Notes: peak sound pressure levels (Pk SPL) dB re 1 µPa; Cumulative sound exposure level (SEL_{24hr}) dB re 1 $\mu Pa^2 \cdot s$. All criteria are presented as sound pressure even for fish without swim bladders since no data for particle motion exist. Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

Given the high mobility of most fish that occur offshore of the 200 m isobath, particularly the highly migratory pelagic species likely to be encountered in deeper water, it is assumed that the majority of fish species would avoid seismic noise at levels below those where physiological injury or mortality would result. Possible injury or mortality in pelagic species could occur on initiation of a sound source at full pressure in the immediate vicinity of fish, or where reproductive or feeding behaviour override a flight response to seismic survey sounds. Many of the pelagic sharks and tunas likely to be encountered in offshore waters also do not have a swim bladder and are thus less susceptible to seismic sounds than those species that do have swim bladders.

The underwater noise modelling study undertaken for the current survey (SLR 2022) identified that the maximum horizontal distance from 3D seismic source to impact threshold levels leading to mortality or potential mortal injury was 90 m, for fish lacking swim bladders (e.g. some tunas, sharks and most mesopelagic species) and 180 m for fish with swim bladders. Zones of immediate impact from single pulses for recovery injury were the same. The zones of potential mortal injuries for fish species without a swim bladder were not reached for the cumulative 24-hour survey operation scenario considered, whereas for fish with swim bladders this distance is 30 m from the adjacent survey lines for 3D sound sources. For recoverable injury, the zones of cumulative impact from multiple pulses were again not reached, but were predicted to be within 80 m from the adjacent survey lines for fish with a swim bladder. The zones of TTS effect for fish species with and without swim bladders are predicted to be within 2 900 m for the cumulative scenario. It must be kept in mind that the cumulative zones of impact are conservative as most fish likely to be encountered in the Orange Basin are the highly migratory pelagic sharks, tunas and billfish, and are likely to have moved considerable distances over the cumulative 24-hr period.

Should an encounter occur, the potential physiological impact on individual migratory pelagic fish, would be of HIGH intensity. Furthermore, the duration of the impact on the population would be

limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL). The impact is therefore considered to be of MEDIUM consequence.

Behavioural avoidance

When interpreting the results of the many studies on potential behavioural effects of sounds on fish one must be cautious of results obtained in tanks or large enclosures and keep in mind that that the responses of fishes may vary with their age and condition, under different environmental conditions and when the level of the sound received by the animal differs (Popper & Hawkins 2019). Behavioural responses to impulsive sounds are varied and include leaving the area of the noise source (Suzuki *et al.* 1980; Dalen & Raknes 1985; Dalen & Knutsen 1987; Løkkeborg 1991; Skalski *et al.* 1992; Løkkeborg & Soldal 1993; Engås *et al.* 1996; Wardle *et al.* 2001; Engås & Løkkeborg 2002; Hassel *et al.* 2004), changes in vertical and horizontal distribution (Chapman & Hawkins 1969; Dalen 1973; Pearson *et al.* 1992; Slotte *et al.* 2004; Løkkeborg *et al.* 2012; Davidsen *et al.* 2019), spatial changes in schooling behaviour (Slotte *et al.* 2004), and startle response to short range start up or high level sounds (Pearson *et al.* 1992; Wardle *et al.* 2001; Paxton *et al.* 2017). Behavioural responses such as avoidance of seismic survey areas and changes in feeding behaviours of some fish to seismic sounds have been documented at received levels of a between 130 and 180 dB re 1 µPa, with disturbance ceasing at noise levels below this (Slabbekoorn *et al.* 2019). In some cases behavioural responses were observed at up to 5 km distance from the firing airgun array (Santulli *et al.* 1999; Hassel *et al.* 2004; Dalen *et al.* 2007; Fewtrell & McCauley 2012), with Paxton *et al.* (2017) demonstrating a 78% decline in multispecies presence at a site 7.9 km away from the survey path during active seismic surveying. In contrast, Miller & Cripps (2013) found no effect of seismic survey on the fish species composition of a coral reef in northern Australia, and Meekan *et al.* (2020, 2021) reported no short-term (days) or long-term (months) effects of seismic exposure on the composition, abundance, size structure, behaviour, or movement of demersal fish fauna on the North West Shelf of Western Australia.

Based on the noise exposure criteria provided by Popper *et al.* (2014), relatively high to moderate behavioural risks are expected at near to intermediate distances (tens to hundreds of meters) from the source location. Relatively low behavioural risks are expected for fish species at far field distances (thousands of meters) from the source location. Behavioural effects are generally short-term, however, with duration of the effect being less than or equal to the duration of exposure, although these vary between species and individuals, and are dependent on the properties of the received sound. Although changes in fish distribution have been reported during and after airgun operations, they generally returned to the original site within hours or days after the end of the seismic operation (Engås *et al.* 1996; Engås & Løkkeborg 2002). In some cases behaviour patterns returned to normal within minutes of commencement of surveying indicating habituation to the noise (Davidsen *et al.* 2019) or showed no reaction at all (Peña *et al.* 2013; Miller & Cripp 2013; Meekan *et al.* 2021). Disturbance of fish is believed to cease at noise levels below 160 dB re 1µPa. The ecological significance of such effects is therefore expected to be low, except in cases where they influence reproductive activity, interfere with foraging or feeding, disruption of migrations and habitat selection or result in delayed mortality (Hirst & Rodhouse 2000; Popper & Hawkins 2019; Soudijn *et al.* 2020). Sub-lethal impacts of acoustic disturbance such as changes in activity patterns and energy budgets can result in altered food intake and growth rates, indirectly affecting the age at sexual maturity, survival and fecundity, thereby ultimately leading to population level consequences (Bruce *et al.* 2018; Cox *et al.* 2018; Slabbekoorn *et al.* 2019; Soudijn *et al.* 2020; van der Knaap *et al.* 2021). As hearing sensitivity can vary with life-cycle stage, season, locality and duration of shooting (Hirst &

Rodhouse 2000), it is difficult to determine with accuracy the impact of seismic sound on the behaviour of fish (Gausland 2003).

Changes in spawning, migration and feeding behaviour of fishes in response to seismic shooting could indirectly affect fisheries through reduced catches resulting from changes in feeding behaviour, abundance and vertical distribution (Skalski *et al.* 1992; Hirst & Rodhouse 2000; Gausland 2003). Such behavioural changes could lead to changes in commercial catch rates if fish move out into or out of important fishing grounds (Engås *et al.* 1996; Hirst & Rodhouse 2000; Dalen & Næsted 2008; Streever *et al.* 2016; Bruce *et al.* 2018). Reports on observed declines in catch rates differ considerably between studies, between target species and gear types used, ranging from no apparent reduction to an 83% reduction in bycatch in a shrimp trawl (Løkkeborg & Soldal 1993) and typically persisting for a relatively short duration only (12 hours to up to 10 days).

The distance from the seismic sound source at which reductions in catch rates were measured also varied substantially between studies ranging from no significant effects in trawl, trammel net and hydraulic dredging fisheries (La Bella *et al.* 1996), through approximately 8 km to as much as 36 km (Hirst & Rodhouse 2000; see also Cochrane & Wilkinson 2015). The potential effects of seismic surveys on fisheries are discussed in more detail in the Commercial Fisheries Impact Assessment (Japp & Wilkinson 2022). Airgun noise related changes to prey and predator species of commercially important species could also play a role in affecting catch rates (Hirst & Rodhouse 2000). Information on feeding success of fish (or larger predators) in association with seismic survey noise is lacking.

Seismic activities have been predicted to possibly affect the migration patterns of tuna leading to substantially reduced catches of albacore and southern bluefin tuna in southern Namibia and the Great Australian Bight, respectively. In the Benguela region it has been suggested that the seasonal movement of longfin tuna northwards from the west coast of South Africa into southern Namibia may be disrupted by the noise associated with seismic surveys. Longfin and other tuna species migrations are known to be highly variable from year to year and are associated with prey availability and also favourable oceanographic conditions. While the potential exists to disrupt the movement of longfin tuna in the Benguela, this disruption, if it occurs, would be localised spatially and temporarily and would be compounded by environmental variability. Similar uncertainty has been expressed for southern bluefin tuna in the Great Australian Bight, and there too there is much uncertainty and any changes in movement and or availability of bluefin tuna was compounded by inter-annual variability and no direct cause and effect could yet be attributed to seismic surveys (Evans *et al.* 2018). As there is currently a dearth of information on the impacts of seismic noise on truly pelagic species such as swordfish and tuna (Evans *et al.* 2018; Webster *et al.* 2018), links between changes in migration patterns and subsequent catches thus remains speculative.

Behavioural responses such as deflection from migration paths or avoidance of seismic survey areas and changes in feeding behaviours of some fish to seismic sounds have been documented at received levels of about 130 - 180 dB re 1 µPa. Behavioural effects are generally short-term, however, with duration of the effect being less than or equal to the duration of exposure, although these vary between species and individuals, and are dependent on the properties of the received sound. The potential impact on individual fish behaviour could therefore be of HIGH intensity (particularly in the near-field of the airgun array). Impacts to behavioural responses would be limited to the survey duration (IMMEDIATE), and the survey area (REGIONAL). Consequently it is considered to be of MEDIUM consequence.

Reproductive success / spawning

BL28

Although the effects of airgun noise on spawning behaviour of fish have not been quantified to date, it is predicted that if fish are exposed to powerful external forces on their migration paths or spawning grounds, they may be disturbed or even cease spawning altogether (de Jong *et al.* 2020). The deflection from migration paths may be sufficient to disperse spawning aggregations and displace spawning geographically and temporally, thereby affecting recruitment to fish stocks. The magnitude of effect in these cases will depend on the biology of the species and the extent of the dispersion or deflection. Depending on the physical characteristics of the area, the range of the impact may extend beyond 30 km (Dalen *et al.* 2007), and could thus potentially affect subsequent recruitment to fish stocks if spawning is displaced geographically or temporally. Dalen *et al.* (1996), however, recommended that in areas with concentrated spawning or spawning migration seismic shooting be avoided at a distance of ~50 km from these areas, particularly areas subjected to repeated, high intensity surveys (see also Gausland 2003). In Norway, legislation has now been put in place ensuring that areas supporting high densities of spawning fish are sometimes closed to seismic surveys as a measure both to avoid scaring away the spawning adults and to avoid direct mortality of early life stages (Boertmann *et al.* 2009; Sivle *et al.* 2021). A buffer of 20 nautical miles around Norwegian spawning grounds has now been recommended to be closed for 3D seismic surveys (Sivle *et al.* 2021). To effectively protect spawning areas, however, thorough knowledge of the actual spawning areas and periods of the species involved is crucial.

The spawning areas of the small pelagic shoaling species are distributed on the continental shelf and along the shelf edge from Lambert's Bay to Mossel Bay, with the major spawning grounds for most species (anchovy, round herring, horse mackerel, chub mackerel) located east of Cape Point and hake spawning occurring on the western Agulhas Bank. There is therefore no overlap of the proposed 3D survey area with the migration routes and spawning areas of these commercially important species (see Figure 17). If behavioural responses to seismic noise result in deflection from coastal migration routes or disturbance of spawning, further impacts may occur that may affect recruitment to fish stocks. The intensity of effect in these cases will depend on the biology of the species and the extent of the dispersion or deflection. Despite the current low biomass of sardine, particularly west of Cape Agulhas, recent successive years of low recruitment and the dependence of future recruitment on successful West Coast spawning (Shabangu *et al.* 2019b) the intensity of the potential impact of the 3D survey can be considered VERY LOW for the duration of the survey (IMMEDIATE) as the survey area lies well offshore of these West Coast spawning areas and is not known to be a spawning area for large pelagic species. The impact is thus considered to be of VERY LOW consequence.

Masking of environmental sounds and communication

While some nearshore reef species are known to produce isolated sounds or to call in choruses, communication and the use of environmental sounds by fish off the South African West Coast are unknown. Demersal species in abyssal and continental slope habitats or associated with Child's Bank or Tripp Seamount would receive the seismic noise in the far field and vocalisation, should it occur, is unlikely to be masked. Impacts arising from masking of sounds are thus expected to be of VERY LOW intensity due to the duty cycle of seismic surveys in relation to the more continuous biological noise. Such impacts would occur across the survey area (REGIONAL) and for the duration of the survey (1.5 months). The impact is thus considered to be of VERY LOW consequence.

Indirect impacts due to effects on predators or prey

The assessment of indirect effects of seismic surveys on fish is limited by the complexity of trophic pathways in the marine environment. The impacts are difficult to determine, and would depend on

the diet make-up of the fish species concerned and the effect of seismic surveys on the diet species. Indirect impacts of seismic surveying could include attraction of predatory species such as sharks, tunas or diving seabirds to pelagic shoaling fish species stunned by seismic noise. In such cases, where feeding behaviour overrides a flight response to seismic survey sounds, injury or mortality could result if the seismic sound source is initiated at full power in the immediate vicinity of the feeding predators. Little information is available on the feeding success of large migratory fish species in association with seismic survey noise. The pelagic shoaling species that constitute the main prey item of migratory pelagic species typically occur inshore of the 200 m depth contour. Although large pelagic species are known to aggregate around seamounts to feed, considering the extensive range over which large pelagic fish species can potentially feed in relation to the survey area, and the low abundance of pelagic shoaling species that constitute their main prey across most of the 3D survey area the intensity of the impact would be LOW, restricted to the survey area (REGIONAL) and persisting over the IMMEDIATE-TERM only (1.5 months). The impact would thus be of VERY LOW consequence.

Impact Significance

Physiological injury and mortality

The potential impact of seismic noise on physiological injury or mortality of fish, considering their high sensitivity and medium consequence, is thus deemed to be of MEDIUM significance.

Behavioural avoidance

The potential impact of seismic noise on behavioural changes in large migratory pelagic fish, considering the high sensitivity, the low to medium likelihood of the impact occurring and medium consequence, is deemed to be of MEDIUM significance.

Reproductive success / spawning

The potential impact of seismic noise on the reproductive success and spawning of nearshore commercial fish species, considering their high sensitivity, the low to medium likelihood of the impact occurring and the very low consequence, is deemed to be of LOW significance.

Masking of environmental sounds and communication

The potential impact of seismic noise on the masking of sounds of fish, considering the high sensitivity, the low likelihood of the impact occurring and the very low consequence is thus deemed to be of LOW significance.

Indirect impacts due to effects on predators or prey

The potential indirect impact of seismic noise on food sources for fish, considering their high sensitivity, the low likelihood of the impact occurring and the very low consequence, is thus deemed to be of LOW significance.

Identification of Mitigation Measures

As the proposed survey area is located far offshore, it is not deemed necessary to implement mitigation measures to avoid the key spring spawning periods for most commercially important fish species. Furthermore, TGS has agreed to avoid the key "ring fenced" fishing and spawning areas identified during previous consultation with the commercial fishing sector. In addition to the mitigation measures recommended for cetaceans, the following is recommended for fish:

No.	Mitigation measure	Classification
1	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if during daylight hours it is confirmed visually by the MMO during the pre-shoot watch (60 minutes) that there are no shoaling large pelagic fish within 500 m of the seismic source.	Avoid / Abate on site
2	Undertake the survey from North to South to avoid the spring and summer spawning along the shelf edge and on the continental shelf south of St Helena Bay.	Avoid / Abate on site
3	In the case of shoaling large pelagic fish being observed within the mitigation zone, delay the "soft-start" until animals are outside the 500 m mitigation zone.	Avoid / Abate on site
4	Terminate seismic shooting on – Observation of slow swimming large pelagic fish (including whale sharks, basking sharks and manta rays) within the 500 m mitigation zone. – Observation of any obvious mass mortalities of fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO to be as a direct result of the survey. For slow swimming large pelagic fish, terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required).	Abate on site

Residual Impact Assessment

The potential impacts cannot be eliminated due to the nature of the seismic sound source required during surveying. The location of the proposed survey area well to the west of the 'ring-fenced' area and proposed mitigation measures, which are essentially designed to keep animals out of the immediate area of impact and thereby reduce the risk of deliberate injury to fish, reduces the intensity of the impacts relating to physiological injury / mortality to medium, the residual impact will reduce to low consequence and be of LOW significance. All other impacts on fish remain of LOW significance.

4.3.6 Impacts of Seismic Noise on Marine Invertebrates

Source of Impact

The project activities that will result in impacts to marine invertebrates are listed below.

Project phase	Activity
Mobilisation	N/A
Operation	Seismic acquisition/ firing of airguns
Demobilisation	N/A

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition.

Impact Description

Many marine invertebrates have tactile organs or hairs (termed mechanoreceptors), which are sensitive to hydro-acoustic near-field disturbances, and some have highly sophisticated statocysts, which have some resemblance to the ears of fishes (Offutt 1970; Hawkins & Myrberg 1983; Budelmann 1988, 1992; Packard *et al.* 1990; Popper *et al.* 2001) and are thought to be sensitive to the particle acceleration component of a sound wave in the far-field. Potential impacts of seismic pulses on invertebrates would include physiological injury or mortality in the immediate vicinity of the airgun

sound source, and behavioural avoidance. Masking of environmental sounds and indirect impacts due to effects on predators or prey have not been documented and are highly unlikely and are thus not discussed further here.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

The proposed 3D survey area lies well offshore where the ecosystem threat status is considered of 'Least concern'. The proposed 3D acquisition area lies well offshore where the deepwater habitat types are comparatively uniform and cover large areas. The benthic fauna of the abyss, lower and upper continental slope and outer shelf (beyond ~450 m depth) are very poorly known and there are no species of commercial value occurring that far offshore. Sensitive deep-water coral communities would be expected with topographic features such as Tripp Seamount and Childs Bank, which lie ~25 km to the north and 30 km east of the survey area, respectively, but are unlikely to occur in the survey area. Furthermore, most ecosystem types outside the offshore MPAs are either poorly protected or not protected at all (see Figure 41). Pelagic invertebrates that may occur in the Orange Basin are the giant squid, which is a deep dwelling species confined to the continental slopes. This species could thus potentially occur in the survey area, although the likelihood of encounter is extremely low.

The sensitivity of benthic invertebrates is considered to be VERY LOW, whereas for neritic and pelagic invertebrates the sensitivity can be considered LOW. Following the precautionary principle, the LOW sensitivity will be assumed in determining the significance.

Consequence of Impact

Information on hearing by invertebrates, and noise impacts on them is sparse (reviewed in Moriyasu *et al.* 2004; Carroll *et al.* 2017). Although many invertebrates cannot sense the pressure of a sound wave or the lower amplitude component of high frequency sounds, low frequency high amplitude sounds may be detected *via* the mechanoreceptors, particularly in the near-field of such sound sources (McCauley 1994). Sensitivity to near-field low-frequency sounds or hydroacoustic disturbances has been recorded for the lobster *Homarus americanus* (Offut 1970; Day *et al.* 2016a; Fitzgibbon *et al.* 2017), cephalopods (Kaifu *et al.* 2008; Hu *et al.* 2009; Mooney *et al.* 2010, 2012; André *et al.* 2011; Fewtrell & McCauley 2012; Samson *et al.* 2014; Mooney *et al.* 2016), scallops (Day *et al.* 2016; Day *et al.* 2017), and various other invertebrate species (Horridge 1965, 1966; Horridge & Boulton 1967; Moore & Cobb 1986; Packard *et al.* 1990; Tumpenney & Nedwell 1994).

Physiological injury

Recent field-based methods on scallop beds (*Pecten fumatus* and *Mimachlamys asperrima*) in the Bass Strait, Australia, showed no evidence of scallop mortality attributable to seismic surveying, although sub-lethal effects could not be excluded (Przeslawski *et al.* 2016, 2018; see also Parry *et al.* 2002; Harrington *et al.* 2010). Another study on exposure of scallops from transplanted populations to an airgun operated in shallow water (<12 m), however, found evidence of seismic impacts (increased

mortality, inability to maintain homeostasis, reflex changes, depressed immune response) (Day *et al.* 2016, 2017).

No other quantitative records of invertebrate mortality from seismic sound exposure under field operating conditions have been reported, although lethal and sub-lethal effects have been observed under experimental conditions where invertebrates were exposed to airguns at close range (reviewed by Carroll *et al.* 2017). These include reduced growth and reproduction rates, compromised nutritional condition and immunological capacity, and behavioural changes in crustaceans (DFO 2004; McCauley 1994; McCauley *et al.* 2000; Day *et al.* 2016; Fitzgibbon *et al.* 2017). The effects of seismic survey energy on snow crab (*Chionoecetes opilio*) on the Atlantic coast of Canada, for example ranged from no physiological damage (Lee-Dadswell 2009), but effects on developing fertilized eggs at 2 m range (Christian *et al.* 2003) to possible bruising of the heptopancreas and ovaries, delayed embryo development, smaller larvae, and indications of greater leg loss but no acute or longer term mortality and no changes in embryo survival or post hatch larval mobility (DFO 2004). In contrast, Day *et al.* (2016, 2019, 2021) demonstrated delayed righting time, which was correlated to damage to statocysts in adult rock lobster (*Jasus edwardsii*) persisting up to a year after exposure to airgun sounds, despite larval stages showing no adverse effects (Day *et al.* 2017, 2019). Impairments in righting behaviour were found to extend to at least 500 m form the airgun discharge, with those closest to the source demonstrating both persistent righting impairment and an increased intermoult duration (Day *et al.* 2019, 2021). The ecological significance of sub-lethal or physiological effects could thus range from trivial to important depending on their nature. It must be kept in mind, however, that assessing seismic impacts using experimental cages or tanks is challenging due to experimental artefacts (Gray *et al.* 2016; Rogers *et al.* 2016) that may lead to misinterpretation of impact in field settings (e.g. DeSoto *et al.* 2013) who reported developmental delays in scallop (*Pecten novaezelandiae*) larvae exposed to playbacks of seismic pulses).

Other field-based studies on adult invertebrate populations revealed no evidence of increased mortality in response to airgun exposure in scallops, clams or lobsters, a variety of reef-associated invertebrates, snowcrabs and shrimp (reviewed in Carroll *et al.* 2017). Day *et al.* (2016a), however, reported dose-dependent increased mortality in transplanted scallops reared in suspended lantern nets four months after exposure to an airgun.

More recently, some studies have also been undertaken on invertebrates that lack statocysts to determine potential non-auditory impacts. Hastings (2008) suggested that at high levels (~260 dB re 1 µPa) hydroacoustic force could potentially cause skeletal and tissue damage in corals. Direct mortality of invertebrates from hydroacoustic force has been considered unlikely (Department of Fisheries and Oceans Canada 2004; Massey & Forde 2015). In a structured infield before-after/control-impact study, no measurable effects on skeletal integrity, physiological damage or stress, and no evidence of a behavioural response in adult scleractinian corals in 30 - 70 m depth at Scott Reef, northwest Australia, were detected immediately after and up to four months following a 3D seismic survey (maximum SEL of 204dB re 1µPa^2) (Battershill *et al.* 2007, 2008; Heyward *et al.* 2018). Heyward *et al.* (2018) point out that the study did not, however, consider sub-lethal or incipient damage to corals or their habitat, such as reduced reproduction, behavioural or physiological changes and slower growth.

Although causative links to seismic surveys have not been established with certainty, giant squid strandings coincident with seismic surveys have been reported (Guerra *et al.*, 2004; Leite *et al.* 2016). The animals examined by Guerra *et al.* (2004) following two incidents of multiple strandings in the

Bay of Biscay showed no external damage, but all had severe internal injuries (including disintegrated muscles and unrecognisable organs) indicative of having ascended from depth too quickly. Similarly, exposure of various species of caged Mediterranean cephalopods to low frequency sounds revealed lesions in the statocysts, consistent with a massive acoustic trauma (André *et al.* 2011; Solé *et al.* 2013a, 2013b).

Behavioural avoidance

Behavioural responses of invertebrates to particle motion of low frequency stimulation have been measured by numerous researchers (reviewed in McCauley 1994). Again a wide range of responses are reported ranging from no avoidance by free ranging invertebrates (crustaceans, echinoderms and molluscs) of reef areas subjected to pneumatic airgun fire (Wardle *et al.* 2001), and no reduction in catch rates of shrimp (Webb & Kempf 1998; Andriguetto-Filho *et al.* 2005), prawns (Steffe & Murphy 1992, in McCauley, 1994) or rock lobsters (Parry & Gason 2006) or snow crab (Courtenay *et al.* 2009; Cote *et al.* 2020) in the near-field during or after seismic surveys. Startle responses and alarm behaviour in decapods occurred only when the animals were <0.10 m away from the sound source (Goodall *et al.* 1990). Day *et al.* (2017), however, demonstrated a reduction in classic behaviours and the development of a nonclassic velar 'flinch' of scallops in response to airgun signals. Branscomb & Rittschof (1984), however, reported that low frequency noise was successful in deterring barnacle larvae from settling on ship hulls. Changes in predator avoidance behaviours may, however, have population-level implications if predation rates increase due to sound-induced behavioural changes in prey (reviewed in Carroll *et al.* 2017; see also Day *et al.* 2019). Solan *et al.* (2016) showed that exposure to underwater broadband sound fields altered sediment-dwelling invertebrate contributions to fluid and particle transport. Thus despite the effects of the sound not being lethal, it could have significant functional, fitness and ecological consequences by affecting key processes in benthic nutrient cycling).

Cephalopods, in contrast, may be receptive to the far-field sounds of seismic airguns, with reported responses to frequencies under 400Hz including alarm response (e.g. jetting of ink), changes in behaviour (aggression and spawning), position in the water column and swimming speeds (Kaifu *et al.* 2008; Hu *et al.* 2009; Mooney *et al.* 2010, 2012; Fewtrell & McCauley 2012; Samson *et al.* 2014; Mooney *et al.* 2016). Squid responded to sounds from 80 to 1 000 Hz pure tone and at sound levels above 140 dB re. 1 µPa rms, with response rates diminishing at the higher and lower end of this range (Samson *et al.* 2014; Mooney *et al.* 2016). In contrast Maniwa (1976) reported attraction at 600 Hz pure tone. Behavioural responses, however, typically involved startle responses at received levels of 174 dB re 1 µPa, to increase levels of alarm responses once levels had reached 156 - 161 dB re 1 µPa (McCauley *et al.* 2000; Fewtrell & McCauley 2012), which is well below the maximum range of 230-255 dB re 1µPa at 1 m for airgun arrays. The results of caged experiments suggest that squid would significantly alter their behaviour at an estimated 2 - 5 km from an approaching large seismic source, although recent research has shown that gradual increase in signal intensity and prior exposure to air gun noise would decrease the severity of the alarm responses, suggesting that animals became accustomed to the noise at low levels (McCauley *et al.* 2000; Fewtrell & McCauley 2012; Samson *et al.* 2014). Limited avoidance of airgun sounds by mobile neritic and pelagic invertebrates can, however, therefore be expected.

As the proposed 3D survey area is located in waters in excess of 500 m depth, the received noise by benthic invertebrates at the seabed would be within the far-field range, and outside of distances at which physiological injury would be expected. The impact is therefore deemed of VERY LOW intensity

5223

across the survey area (REGIONAL) and for the four-month survey duration (IMMEDIATE) and is therefore considered to be of VERY LOW consequence.

The potential impact of seismic noise on physiological injury or mortality and behavioural avoidance of pelagic cephalopods could potentially be of high intensity to individuals, but as distribution of mobile neritic and pelagic squid is naturally spatially highly variable and the numbers of giant squid likely to be encountered is low, the intensity would be considered LOW across the survey area (REGIONAL) and for the survey duration (IMMEDIATE - 1.5 months) resulting in a VERY LOW consequence.

Impact Significance

The potential impact of 3D seismic noise on benthic, and neritic and pelagic invertebrates, considering the low sensitivity, the low likelihood of the impact occurring is thus deemed to be of NEGLIGIBLE significance.

Identification of Mitigation Measures

The following mitigation measure is however recommended:

No.	[illegible]	[illegible]
1	Terminate seismic shooting on observation of any obvious mass mortalities of squid when estimated by the MMO to be as a direct result of the survey.	Abate on site

Residual Impact Assessment

With the implementation of the typical 'soft-starts', the residual impact on potential behavioural avoidance by cephalopods would remain of NEGLIGIBLE significance.

4.3.7 Impacts of Seismic Noise on Plankton (including Ichthyoplankton)

Source of Impact

The project activities that will result in impacts to plankton are listed below.

Project phase	Activity
Mobilisation	N/A
Operation	Seismic acquisition/ firing of airguns
Demobilisation	N/A

These activities and their associated aspects are described below:

- Noise generated by airguns during seismic acquisition.

Impact Description

As the movement of phytoplankton, zooplankton and ichthyoplankton is largely limited by currents, they are not able to actively avoid the seismic vessel and thus are likely to come into close contact with the sound sources, potentially experiencing multiple exposures during acquisition of adjacent lines. Potential impacts of seismic pulses on plankton would include physiological injury or mortality in the immediate vicinity of the airgun sound source.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

The proposed 3D survey area lies offshore of the the Namaqua and Cape Columbine upwelling cells (see Figure 7a), in the warmer oceanic waters. Phytoplankton and zooplankton abundance in the clear offshore waters of the Benguela Current are thus expected to be low, although seasonal peaks may occur associated with Child's Bank and Tripp Seamount.

The major spawning areas of the small pelagic shoaling species are on the continental shelf and along the shelf edge from Lambert's Bay to Mossel Bay. Hake, snoek and round herring also move to the western Agulhas Bank and southern west coast to spawn, generally in late winter and early spring, although hake are reported to spawn year round. The eggs and larvae are carried around Cape Point and up the West Coast in northward flowing surface waters, except hake whose eggs rise slowly through the water column, remain entrained in the upwelling circulation and are drawn shorewards at depth until just before hatching. At the start of winter every year, the juveniles recruit in large numbers into coastal waters across broad stretches of the shelf between the Orange River and Cape Columbine to utilise the shallow shelf region as nursery grounds before gradually moving southwards in the inshore southerly flowing surface current, towards the major spawning grounds east of Cape Point. There is therefore no overlap of the proposed 3D survey area with the northward egg and larval drift of commercially important species, and the return migration of recruits (see Figure 17).

Phytoplankton are not known to be affected by seismic surveys and are unlikely to show any significant effects of exposure to airgun impulses outside of a 1 m distance (Kosheleva 1992; McCauley 1994). Although subject to nutrient availability, the regeneration time of phytoplankton is rapid so that an

area vacated by mortality through exposure to airgun blasts would be rapidly recolonized. Furthermore, the fast current speeds would ensure rapid displacement and replacement of damaged or dead plankton within the survey area.

Zooplankton comprises meroplankton (organisms which spend a portion of their life cycle as plankton, such as fish and invertebrate larvae and eggs) and holoplankton (organisms that remain planktonic for their entire life cycle, such as siphonophores, nudibranchs and barnacles). The abundance and spatial distribution of zooplankton is highly variable and dependent on factors such as fecundity, seasonality in production, tolerances to temperature, length of time spent in the water column, hydrodynamic processes and natural mortality. Zooplankton densities are therefore generally patchily distributed.

Invertebrate members of the plankton that have a gas-filled flotation aid, may be more receptive to the sounds produced by seismic airgun arrays, and the range of effects may extend further for these species than for other plankton.

Phytoplankton, zooplankton and ichthyoplankton abundances across most of the survey area are thus expected to be comparatively low, and (if they occur) have a highly patchy distribution and seasonally high abundances. Although plankton distribution is naturally temporally and spatially variable and natural mortality rates are high, the overall sensitivity is considered **MEDIUM** due to the potentially reduced reproductive success in some of the small pelagic species.

Consequence of Impact

The amount of exposure that plankton can withstand due to the influence of seismic sound is dependent on a wide range of variables namely 1) the presence of gas-filled flotation aids, 2) temporal and spatial variability in occurrence, and 3) proximity to the sound source. Potential impacts of seismic pulses on plankton, and fish eggs and larvae would include mortality or physiological injury in the immediate vicinity of the airgun sound source

Due to their importance in commercial fisheries, numerous studies have been undertaken experimentally exposing the eggs and larvae of various zooplankton and ichthyoplankton species to airgun sources (Kostyuchenko 1971; Dalen & Knutsen 1987; Holliday *et al.* 1987; Booman *et al.* 1992; Kosheleva 1992; McCauley 1994; Popper *et al.* 2005; and reviewed in Carroll *et al.* 2017 and Shie *et al.* 2021). These studies generally identified that for a large seismic array, mortalities and physiological injuries occurred at very close range (<5 m) only. For example, increased mortality rates for fish eggs were proven out to ~5 m distance from the air guns. A mortality rate of 40-50% was recorded for yolk sac larvae (particularly for turbot) at a distance of 2-3 m (Booman *et al.* 1996), although mortality figures for yolk sac larvae of anchovies at the same distances were lower (Holliday *et al.* 1987). Yolk sac larvae of cod experienced significant eye injuries (retinal stratification) at a distance of 1 m from an air gun array (Matishov 1992), and Booman *et al.* (1996) report damage to brain cells and lateral line organs at <2 m distance from an airgun array. Increased mortality rates (10-20%) at later stages (larvae, post-larvae and fry) were proven for several species at distances of 1-2 m. Changes have also been observed in the buoyancy of the organisms, in their ability to avoid predators and effects that affect the general condition of larvae, their growth rate and thus their ability to survive. Temporary disorientation juvenile fry was recorded for some species (McCauley 1994). McCauley (1994) concluded that when compared with total population sizes or natural mortality rates of planktonic organisms, the relative influence of seismic sound sources on these populations can be considered insignificant. The wash from ships propellers and bow waves can be

expected to have a similar, if not greater, volumetric effect on plankton than the sounds generated by airgun arrays.

More recently, however, McCauley *et al.* (2017) demonstrated significant declines in zooplankton abundance within a maximum range of 1.2 km of the airguns' passage (see also Tollefson 2017) and suggested that seismic surveys may result in significant and unacknowledged impacts on ocean ecosystem function and productivity. A follow-up publication by Richardson *et al.* (2017), however, queried the robustness of the McCauley *et al.* (2017) study on the grounds of insufficient sample size. Richardson *et al.* (2017) estimated that while zooplankton populations declined 22% within the survey area and 14% within 15 km of the survey area, biomass recovery occurred within 3 days following survey completion and any effects on zooplankton by seismic noise would endure in the very short term only. The time required for recolonisation of the water column by zooplankton (and ichthyoplankton) would depend on a number of variables, including seasonality of zooplankton spawning, water movement, vertical migration of plankton species and proximity of breeding adult populations. The authors stressed that impacts in areas of dynamic ocean circulation (as would be the case in the offshore reaches of the Benguela Current, are likely to be even less. A more recent study by Fields *et al.* (2019) reported that there was significantly higher immediate mortality of the copepod *Calanus finmarchicus* at distances of 5 m from the airguns compared to controls, but that increased mortality did not exceed 30% at any distance from airgun blasts. Whether it was the sound pulse itself, the large-scale fluid motion generated by the airgun blasts, or other effects such as the bubble cloud that caused the higher mortality in the copepods, however, remains unknown.

From a fish resource perspective, these effects may potentially contribute to a certain diminished net production in fish populations, both directly through mortality of ichthyoplankton, as well as indirectly through reduction in plankton that serves as a food source. However, Sætre & Ona (1996) calculated that under the "worst case" scenario, the number of larvae killed during a typical seismic survey was 0.45% of the total larvae population. When more realistic "expected values" were applied to each parameter of the calculation model, the estimated value for killed larvae during one run was equal to 0.03% of the larvae population. If the same larval population was exposed to multiple seismic runs, the effect would add up for each run. For species such as cod, herring and capelin, the natural mortality is estimated at 5-15% per day of the total population for eggs and larvae. This declines to 1-3% per day once the species reach the 0 group stage *i.e.* at approximately 6 months (Sætre & Ona 1996). Consequently, Dalen *et al.* (1996) concluded that seismic-created mortality is so low that it can be considered to have an inconsequential impact on recruitment to the populations. Furthermore, due to the rate at which airguns are discharged, and the fact that the vessel is continuously moving, it is highly unlikely that eggs and larvae will be repeatedly exposed to harmful sound waves (Dalen & Raastad 2008). In Norway, where until 1996 recommendations limiting seismic surveys in areas with drifting eggs and larvae had been in place, these were reviewed to allow surveying in areas of high ichthyoplankton abundance. However, restrictions for spawning areas and areas with spawning migrations, remained in place (Sivle *et al.* 2021)..

A peak SPL of >207 dB has been established for mortality and potential mortal injury of fish eggs and larvae (see Table 14). Based on the noise exposure criteria provided by Popper *et al.* (2014), the Underwater Noise Modelling Study undertaken for the survey (SLR 2022) identified that the maximum horizontal distance from the seismic source to impact threshold levels for fish eggs and larvae leading to mortality or potential mortal injury was 180 m. The zones of cumulative impact from multiple pulses (i.e. the maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels), was estimated at 10 m. Maximum threshold distances for recoverable injury

228

and temporary threshold shifts (TTS) for fish eggs and larvae were not reached. Impacts will thus be of high intensity at close range.

As the 3D survey is scheduled for the summer survey window (start December to end May), there will be some temporal overlap with the peak spawning products of commercially important species. However, as plankton distribution is naturally temporally and spatially variable and natural mortality rates are high, and the survey area lies west of the West Coast northward egg and larval drift and return migration of recruits, any impacts would be of LOW intensity for phytoplankton and zooplankton, but of MEDIUM intensity for ichthyoplankton. Although the impact is restricted to within a few hundred metres of the airguns, it would extend over the entire survey area (REGIONAL). Should impacts occur, they would persist over the IMMEDIATE-TERM (days) in the case of phytoplankton and zooplankton only due to the rapid natural turn-over rate of these plankton communities, but would persist over the SHORT-term in the case of ichthyoplankton (particularly the sardine stock, which is experiencing successive years of low recruitment). The consequence of the impact would therefore be VERY LOW for phytoplankton and zooplankton but MEDIUM for ichthyoplankton. As plankton abundances in the offshore waters of the proposed 3D survey area will be negligible, the consequence of the impact would be VERY LOW.

Impact Significance

The potential impact of seismic noise on phytoplankton and zooplankton, considering the medium sensitivity and very low consequence, is thus deemed to be of VERY LOW significance both with and without mitigation. Due to the medium consequence and medium sensitivity of ichthyoplankton, but the low likelihood of the impact occurring in offshore waters, the impacts are deemed to be of MEDIUM significance.

Identification of Mitigation Measures

As the proposed survey area is located far offshore, it is not deemed necessary to implement mitigation measures to avoid the key spring spawning periods thereby mitigating potential impacts on plankton to some degree. In addition, TGS has agreed to avoid the key "ring fenced" fishing and spawning areas in the south-east of the reconnaissance permit area identified during previous consultation with the commercial fishing sector. No other direct mitigation measures for potential impacts on plankton and fish egg and larval stages are feasible or deemed necessary.

Residual Impact Assessment

This potential impact cannot be eliminated due to the nature of the seismic sound source required during surveying. With the implementation of the above mitigation measure, the residual impact would reduce to VERY LOW significance.

4.3.8 Impacts of Seismic Noise at Ecosystem Level

Figure 48 provides a simplified conceptual model for the nearshore and offshore receiving environment on the West and South-West Coasts illustrating key variables, processes, linkages, relationships, dependencies and feed-back-loops.

The upwelling of nutrients in the southern Benguela is the main driver that supports substantial seasonal phytoplankton production, which in turn serves as the basis for a rich food chain up through zooplankton, pelagic fish, cephalopods, and marine mammals, as well as demersal species and benthic fauna. High phytoplankton productivity in the upper layers again depletes the nutrients in these surface waters, resulting in a wind-related cycle of plankton production, mortality, sinking of detritus and eventual nutrient enrichment and remineralisation through the microbial loops active in the water column and on the seabed. The natural annual input of millions of tons of organic material onto the seabed provides most of the food requirements of the particulate and filter-feeding benthic communities, resulting in the high organic content of the muds in the region. Organic detritus not directly consumed enters the seabed decomposition cycle, potentially resulting in the depletion of oxygen in deeper waters and the formation of hydrogen sulphide by anaerobic bacteria.

In the offshore oceanic environment in the vicinity of a seamount, similar processes of decomposition and remineralisation, upwelling of nutrients and enhanced localised primary and secondary production would apply, thereby serving as focal points for higher order consumers. The cold-water corals typically associated with seamounts and canyons also add structural complexity to otherwise uniform seabed habitats thereby creating areas of high biological diversity and the development of detritivore-based food-webs, which in turn lead to the presence of seamount scavengers and predators. Seamounts also provide an important habitat for commercial deepwater fish stocks.

Figure 48: Simplified network diagram indicating the interaction between the key ecosystem components off the West Coast.

Ecosystem functions of the offshore deep water environment include the support of highly productive fisheries, the dissolution of CO_2 from the atmosphere and subsequent sequestering of carbon in seabed sediments, as well as waste absorption and detoxification.

The structure and function of these nearshore and offshore marine ecosystems is influenced both by natural environmental variation (e.g. El Niño Southern Oscillation (ENSO)) and multiple human uses, such as hydrocarbon developments and the harvest of marine living resources. The review provided in the impact assessment illustrates that the impacts of anthropogenic noise, at various scales surrounding the stressor, have been recorded in a diverse range of faunal groups. Studies on acoustic impacts, however, largely deal with effects upon individual animals or species, with impacts across large spatial scales, cumulative effects (both of ocean noise and factors other than sound pollution) or multiple species and/or food web levels having rarely been considered.

Below follows a brief discussion of potential population-level and ecosystem-wide effects of disturbance and the application of the integrated ecosystem assessment framework for evaluating the cumulative impacts of multiple pressures on multiple ecosystem components.

With growing evidence of the ecosystem-wide effects of seismic noise (Nieukirk *et al.* 2012; Kavanagh *et al.* 2019; Kyhn *et al.* 2019) and the potential consequences of sub-lethal anthropogenic sounds affecting marine animals at multiple levels (e.g. behaviour, physiology, and in extreme cases survival), there is increasing recognition for the need to consider the effects of anthropogenic noise at population and ecosystem level. The sub-lethal effects of sound exposure may seem subtle, but

small changes in behaviour can lead to significant changes in feeding behaviour, reductions in growth and reproduction of individuals (Pirotta *et al.* 2018), but can have effects that go beyond a single species and may cause changes in food web interactions (Francis *et al.* 2009; Hubert *et al.* 2018; Slabbekoorn & Halfwerk 2009).

For example, the intensified upwelling events associated with the Cape Canyon, provide highly productive surface waters, which power feeding grounds for cetaceans and seabirds (www.environment.gov.za/dearesearchteamreturnfromdeepseaexpedition). Roman & McCarthy (2010) demonstrated the importance of marine mammal faecal matter in replenishing nutrients in the euphotic zone, thereby locally enhancing primary productivity in areas where whales and/or seals gather to feed (see also Kanwisher & Ridgeway 1983; Nicol *et al.* 2010). Surface excretion may also extend seasonal plankton productivity after a thermocline has formed, and where diving and surfacing of deep-feeding marine mammals (e.g. pilot whales, seals) transcends stratification, the vertical movement of these air-breathing predators may act as a pump bringing nutrients below the thermocline to the surface thereby potentially increasing the carrying capacity for other marine consumers, including commercial fish species and pelagic and coastal seabirds (Roman & McCarthy 2010). Behavioural avoidance of marine mammals from such seasonal feeding areas in response to increasing anthropogenic disturbance may thus alter the nutrient fluxes in these zones, with possible ecosystem repercussions.

Likewise, long-lived, slow-reproducing species play important stabilizing roles in the marine ecosystem, especially through predation, as they play a vital role in balancing and structuring food webs, thereby maintaining their functioning and productivity. Should such predators be impacted by hydrocarbon exploration at population level (either directly on individuals or indirectly through loss of prey) and this have repercussions across multiple parts of a food web, top-down trophic cascades in the marine ecosystem could result (Ripple *et al.* 2016).

At the other end of the scale, significant impacts on plankton by anthropogenic sources can have significant bottom-up ripple effects on ocean ecosystem structure and health as phytoplankton and their zooplankton grazers underpin marine productivity. Healthy populations of fish, top predators and marine mammals are not possible without viable planktonic productivity. Furthermore, as a significant component of zooplankton communities comprises the egg and larval stages of many commercial fisheries species, large-scale disturbances (both natural and anthropogenic) on plankton communities can therefore have knock-on effects on ecosystem services across multiple levels of the food web.

Due to the difficulties in observing population-level and/or ecosystem impacts, numerical models are needed to provide information on the extent to which sound or other anthropogenic disturbances may affect the structure and functioning of populations and ecosystems. Attempts to model noise-induced changes in population parameters were first undertaken for marine mammals using the population consequences of acoustic disturbance (PCAD) or Population Consequences of Disturbance (PCoD) approach (NRC 2005). The PCAD/PCoD framework assesses how observed behavioural responses on the health of an individual translates into changes in critical life-history traits (e.g. growth, reproduction, and survival) to estimate population-level effects. Since then various frameworks have been developed to enhance our understanding of the consequences of behavioural responses of individuals at a population level. This is typically done through development of bio-energetics models that quantify the reduction in bio-energy intake as a function of disturbance and assess this reduction against the bio-energetic need for critical life-history traits (Costa *et al.* 2016; Keen *et al.* 2021). The

5228

consequences of changes in life-history traits on the development of a population are then assessed through population modelling. These frameworks are usually complex and under continual development, but have been successfully used to assess the population consequences and ecosystem effects of disturbance in real-life conditions both for marine mammals (Villegas-Amtmann 2015, 2017; Costa *et al.* 2016; Ellison *et al.* 2016; McHuron *et al.* 2018; Pirotta *et al.* 2018; Dunlop *et al.* 2021), fish (Slabbekoorn & Halfwerk 2009; Hawkins *et al.* 2014; Slabbekoorn *et al.* 2019) and invertebrates (Hubert *et al.* 2018). The PCAD/PCoD models use and synthesize data from behavioural monitoring programs, ecological studies on animal movement, bio-energetics, prey availability and mitigation effectiveness to assess the population-level effects of multiple disturbances over time (Bröker 2019).

Ecosystem-based management is a holistic living resource management approach that concurrently addresses multiple human uses and the effect such stressors may have on the ability of marine ecosystems to provide ecosystem services and processes (e.g. recreational opportunities, consumption of seafood, coastal developments) (Holsman *et al.* 2017; Spooner *et al.* 2021). Within complex marine ecosystems, the integrated ecosystem assessment framework, which incorporates ecosystem risk assessments, provides a method for evaluating the cumulative impacts of multiple pressures on multiple ecosystem components (Levin *et al.* 2009, 2014; Holsman *et al.* 2017; Spooner *et al.* 2021). It therefore has the potential to address cumulative impacts and balance multiple, often conflicting, objectives across ocean management sectors and explicitly evaluate tradeoffs. It has been repeatedly explored in fisheries management (Large *et al.* 2015) and more recently in marine spatial planning (Hammar *et al.* 2020; Carlucci et al. 2021; Jonsson *et al.* 2021; Harris *et al.* 2022).

However, due primarily to the multi-dimensional nature of both ecosystem pressures and ecosystem responses, quantifying ecosystem-based reference points or thresholds has proven difficult (Large *et al.* 2015). Ecosystem thresholds occur when a small change in a pressure causes either a large response or an abrupt change in the direction of ecosystem state or function. Complex numerical modelling that concurrently identifies thresholds for a suite of ecological indicator responses to multiple pressures is required to evaluate ecosystem reference points to support ecosystem-based management (Large *et al.* 2015).

The required data inputs into such models are currently limited in southern Africa. Slabbekoorn *et al.* (2019) point out that in such cases expert elicitation would be a useful method to synthesize existing knowledge, potentially extending the reach of explicitly quantitative methods to data-poor situations.

4.4 Other Impacts of Seismic Surveys on Marine Fauna

4.4.1 Impact of Vessel and Helicopter Noise on Marine Fauna

Source of Impact

The project activities that will result in an increase in noise impacts on marine fauna are listed below.

Project phase	Activity
Mobilisation	Transit of vessels to survey area
Operation	Operation of survey vessels
	Operation of helicopters
Demobilisation	Survey vessels leave survey area and transit to port or next destination

These activities and their associated aspects are described below:

- The presence and operation of the seismic vessel and support vessels during transit to the survey area, during the proposed survey and during demobilisation will introduce a range of underwater noises into the surrounding water column that may potentially contribute to and/or exceed ambient noise levels in the area.
- Crew transfers by helicopter from Cape Town or a suitable location nearby to the survey vessel, if required (preferred alternative is via the support vessel) will generate noise in the atmosphere that may disturb coastal species such as seabirds and seals. Noise source levels from helicopters are expected to be around 109 dB re 1µPa at the most noise-affected point (SLR Consulting Australia 2019).

Impact Description

Elevated underwater and aerial noise can affect marine fauna, including cetaceans, by:

- causing direct physical injury to hearing;
- masking or interfering with other biologically important sounds (e.g. communication, echolocation, signals and sounds produced by predators or prey);
- causing disturbance to the receptor resulting in behavioural changes or displacement from important feeding or breeding areas.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

The vessel and aircraft noise described above would primarily take place in the survey area and along the route taken by the support vessels and helicopters between the survey area and Cape Town, which has both a commercial port and airport with existing high daily levels of ambient noise. Depending on the location of the seismic vessel at the time of the crew transfer, the flight path between the survey area and Cape Town would potentially cross over offshore and coastal MPAs, and any sensitive coastal receptors (e.g. key faunal breeding/feeding areas, bird or seal colonies and nursery areas for commercial fish stocks). In addition, migratory pelagic species transiting through the survey area

5028

may also be directly affected. Tripp Seamount, which is located approximately 25 km to the north of the survey area in Namibian waters, is also an important feature because it attracts an abundance of marine life and is a productive fishing ground. Tripp Seamount falls outside of any possible flight path or vessel route.

The taxa most vulnerable to disturbance by underwater noise are turtles, and large migratory pelagic fish and marine mammals. Some of the species potentially occurring in the survey area, are considered regionally or globally 'Critically Endangered' (e.g. southern bluefin tuna, leatherback turtles and blue whales), 'Endangered' (e.g. Black-Browed and Yellow-Nosed Albatross, Subantarctic Skua, whale shark, shortfin mako shark, fin and sei whales), 'Vulnerable' (e.g. bigeye tuna, blue marlin, loggerhead turtles, oceanic whitetip shark, dusky shark, great white shark, longfin mako and sperm whale, Bryde's and humpback whales) or 'Near Threatened' (e.g. striped marlin, blue shark, longfin tuna/albacore and yellowfin tuna). Although species listed as 'Critically Endangered' or 'Endangered' may potentially occur in the survey area, due to their extensive distributions their numbers are expected to be low. Based on the low numbers of listed species, the sensitivity is considered to be **MEDIUM**.

Consequence of Impact

Vessel Noise

The ocean is a naturally noisy place and marine animals are continually subjected to both physically produced sounds from sources such as wind, rainfall, breaking waves and natural seismic noise, or biologically produced sounds generated during reproductive displays, territorial defence, feeding, or in echolocation (see references in McCauley 1994). Such acoustic cues are thought to be important to many marine animals in the perception of their environment as well as for navigation purposes, predator avoidance, and in mediating social and reproductive behaviour. Anthropogenic sound sources in the ocean can thus be expected to interfere directly or indirectly with such activities thereby affecting the physiology and behaviour of marine organisms (NRC 2003). Natural ambient noise will vary considerably with weather and sea state, ranging from about 80 to 120 dB re 1 µPa for the frequency range 10 - 10k Hz (Croft & Li 2017). Of all human-generated sound sources, the most persistent in the ocean is the noise of shipping (Erbe *et al.* 2018, 2019). Depending on size and speed, the sound levels radiating from vessels range from 160 to 220 dB re 1 µPa at 1 m (NRC 2003). Especially at low frequencies between 5 to 100 Hz, vessel traffic is a major contributor to noise in the world's oceans, and under the right conditions, these sounds can propagate 100s of kilometres thereby affecting very large geographic areas (Coley 1994, 1995; NRC 2003; Pidcock *et al.* 2003). In the South African EEZ shipping stressors and climate-related stressors are increasing more rapidly than other stressors (Purdon *et al.* 2020b), however, despite these stressors being more pronounced along the shelf and shelf edge of the West Coast, this area boasts the highest cetacean species richness in the oceans around South Africa (Purdon *et al.* 2020b). Consequently, shipping impacts need to be appropriately managed to avoid effects on the population growth rates of the species concerned.

As the proposed survey area falls within with the main offshore shipping routes that pass around southern Africa (see Figure 46), the shipping noise component of the ambient noise environment is expected to be the dominant component within and around the survey area (OceanMind Limited 2020). Shabangu *et al.* (2022) determined that the noise of vessel traffic dominates the soundscape below 500 Hz off the West Coast, while wind-generated noise increased with wind speed above 5 m/s and dominates the soundscape above 500 Hz. Given the significant local shipping traffic and relatively

strong metocean conditions specific to the area, ambient noise levels are expected to be 90 - 130 dB re 1 µPa for the frequency range 10 Hz - 10 kHz (SLR Consulting Australia 2019). The noise generated by the survey vessel, thus falls within the hearing range of most fish and marine mammals, and would be audible for considerable ranges before attenuating to below threshold levels. However, unlike the noise generated by the sound source, underwater noise from vessels is not considered to be of sufficient amplitude to cause direct harm to marine life, even at close range. Due to their extensive distributions, the numbers of pelagic species (large pelagic fish, turtles and cetaceans) encountered during the proposed seismic surveys is expected to be low and consequently the intensity of potential physiological injury or behavioural disturbance as a result of vessel noise would be rated as LOW. Furthermore, the duration of the impact on the populations would be limited to the IMMEDIATE-TERM (1.5 months) and extend REGIONALLY between the survey area and the logistics base. The potential physiological injury or behavioural disturbance as a result of vessel noise would thus be of VERY LOW consequence.

Aircraft Noise

The dominant low-frequency components of aircraft engine noise (10-550 Hz) penetrate the water only in a narrow (26° for a smooth water surface) sound cone directly beneath the aircraft, with the angle of the cone increasing in Beaufort wind force >2 (Richardson *et al.* 1995). The peak sound level received underwater is inversely related to the altitude of the aircraft. More recently, Erbe *et al.* (2018) established that commercial passenger airplanes in a coastal underwater soundscape exhibited broadband received levels of 84-132 dB re 1 µPa rms, detectable at between 12 Hz and 10 kHz and exceeding underwater ambient levels by up to 36 dB. Underwater noise from commercial airplanes would thus be audible to a variety of marine fauna, including seals and dolphins.

Available data indicate that the expected frequency range and dominant tones of sound produced by smaller fixed-wing aircraft and helicopters overlap with the hearing capabilities of most odontocetes and mysticetes (Richardson *et al.* 1995; Ketten 1998; Erbe *et al.* 2017). Determining the reactions of cetaceans to over flights is difficult, however, since most observations are made from either the disturbing aircraft itself (Richardson & Würsig 1997), or from a small nearby vessel. Reactions to aircraft flyovers vary both within and between species, and range from no or minimal observable behavioural response (Belugas: Stewart *et al.* 1982, Richardson *et al.* 1991; Sperm: Clarke 1956, Gambell 1968, Green *et al.* 1992), to avoidance by diving, changes in direction or increased speed of movement away from the noise source (Gray: Withrow 1983; Belugas: Richardson *et al.* 1991; Patenaude *et al.* 2002; Sperm: Clarke 1956; Fritts *et al.* 1983; Mullin *et al.* 1991; Würsig *et al.* 1998; Minke: Leatherwood *et al.* 1982; Bowhead: Patenaude *et al.* 2002; Humpbacks: Smultea *et al.* 1995), separation of cow-calf pairs (Gray: Withrow 1983), increased surface intervals (Belugas: Awbrey & Stewart 1983; Stewart *et al.* 1982; Patenaude *et al.* 2002), changes in vocalisation (Sperm whales: Watkins & Schevill 1977; Richter *et al.* 2003, 2006) and dramatic behavioural changes including breaching and lobtailing (Minke: Leatherwood *et al.* 1982; Sperm: Fritts *et al.* 1983; Bowhead: Patenaude *et al.* 2002; Beluga: Patenaude *et al.* 2002), and active and tight clustering behaviour at the surface (Sperm: Smultea *et al.* 2008).

Most authors established that the reactions resulted from the animals presumably receiving both acoustic and visual cues (the aircraft and/or its shadow). As would be expected, sensitivity of whales to disturbance by an aircraft generally lessened with increasing distance, or if the flight path was off to the side and downwind, and if its shadow did not pass directly over the animals (Watkins 1981; Smultea *et al.* 2008). Smultea *et al.* (2008) concluded that the observed reactions of whales to brief

over flights were short-term and isolated occurrences were probably of no long-term biological significance and Stewart *et al.* (1982) suggested that disturbance could be largely eliminated or minimised by avoiding flying directly over whales and by maintaining a flight altitude of at least 300 m. However, repeated or prolonged exposures to aircraft over flights have the potential to result in significant disturbance of biological functions, especially in important nursery, breeding or feeding areas (Richardson *et al.* 1995).

The reaction of pinnipeds to aircraft noise was reviewed by Richardson *et al.* (1995). As the frequency of aircraft engine noise overlaps with the hearing ranges of seals, these will likely similarly receive both acoustic and visual cues from aircraft flyovers. Richardson *et al.* (1995), however, point out that in very few cases was it determined that responses were specifically to aircraft noise as opposed to visual cues. Furthermore, most reported observations relate to pinnipeds on land or ice, with few data specifically on the reactions of pinnipeds in water to either airborne or waterborne sounds from aircraft. Reactions to flyovers vary between species, ranging from stampeding into the water, through temporary abandonment of pupping beaches to alertness at passing aircraft. When in the water, seals have been observed diving when the aircraft passes overhead. Pinnipeds thus exhibit varying intensities of a startle response to airborne noise, most appearing moderately tolerant to flyovers and habituating over time (Richardson *et al.* 1995; Laws 2009). The rates of habituation also vary with species, populations, and demographics (age, sex). Any reactions to over flights would thus be short-term, except for cases where commercial airports are located close to the coast and overflights are frequent (Erbe *et al.* 2018), and isolated occurrences around the survey vessel would unlikely be of any long-term biological significance or have population-level effects.

The hazards of aircraft activity to birds include direct strikes as well as disturbance, the degree of which varies greatly. The negative effects of disturbance of birds by aircraft were reviewed by Drewitt (1999) and include loss of usable habitat, increased energy expenditure, reduced food intake and resting time and consequently impaired body condition, decreased breeding success and physiological changes. Nesting birds may also take flight and leave eggs and chicks unattended, thus affecting hatching success and recruitment success (Zondrillo 1992). Differences in response to different types of aircraft have also been identified, with the disturbance effect of helicopters typically being higher than for fixed-wing aeroplanes. Results from a study of small aircraft flying over wader roosts in the German Wadden Sea showed that helicopters disturbed most often (in 100% of all potentially disturbing situations), followed by jets (84 %), small civil aircraft (56 %) and motor-gliders (50 %) (Drewitt 1999).

Sensitivity of birds to aircraft disturbance are not only species specific, but generally lessened with increasing distance, or if the flight path was off to the side and downwind. However, the vertical and lateral distances that invoke a disturbance response vary widely, with habituation to the frequent loud noises of landing and departing aircraft without ill effects being reported for species such as gulls, lapwings, ospreys and starlings, amongst others (reviewed in Drewitt 1999). Further work is needed to examine the combined effects of visual and acoustic stimuli, as evidence suggests that in situations where background noise from natural sources (e.g. wind and surf) is continually high, the visual stimulus may have the greater effect.

During the northern migration, animals strike the coast at varying places north of St Helena Bay, resulting in increasing whale density on shelf waters and into deeper pelagic waters as one moves northwards, but no clear migration 'corridor'. Humpbacks could therefore potentially transit through the entire Orange Basin area on their northwards migration. On the southward migration, many

humpbacks follow the Walvis Ridge offshore then head directly to high latitude feeding grounds, while others follow a more coastal route (including the majority of mother-calf pairs) possibly lingering in the feeding grounds off Cape Columbine in summer. Humpback whales are thus likely to be the most frequently encountered baleen whale in the project area, ranging from the coast out beyond the shelf, with year round presence but numbers peaking in July - February and a smaller peak with the southern breeding migration around September - October but with regular encounters until February associated with subsequent feeding in the Benguela ecosystem. Southern Right whales migrate to the southern Africa subcontinent to breed and calve, where they tend to have an extremely coastal distribution mainly in sheltered bays. Winter concentrations have been recorded all along the West Coast extending northwards into southern Namibia. Southern right whales have been recorded off the West Coast in all months of the year, but with numbers peaking in winter (June - September). While in local waters, Southern Rights are found in groups of 1-10 individuals, with cow-calf pairs predominating in inshore nursery areas. Smaller cetaceans in the area include the common dolphin and Heaviside's dolphin, which tend to occur further inshore on the shelf but may be encountered in the shallower portions of the proposed survey area. The level of disturbance of cetaceans by aircraft depends on the distance and altitude of the aircraft from the animals (particularly the angle of incidence to the water surface) and the prevailing sea conditions.

Noise generated by helicopters undertaking crew transfers between the logistics base and the survey vessel could affect seabirds and seals in breeding colonies and roosts on the mainland coast. The nearest seabird colonies to Saldanha airport are on the Saldanha Bay Islands and on the emergent reefs off Cape Columbine. These colonies would fall within the potential flight path between the Saldanha Bay airport and the centre of the proposed 3D survey area. The seal colonies falling within the potential flight paths would similarly be at Cape Columbine. If Cape Town International Airport is used as the logistics base for crew transfers, the flight path would not cross any seabird or seal colonies.

Indiscriminate low altitude flights over whales, seals, seabird colonies and turtles by helicopters used to support the seismic vessel could thus have an impact on behaviour and breeding success. The intensity of disturbance would depend on the distance and altitude of the aircraft from the animals (particularly the angle of incidence to the water surface) and the prevailing sea conditions and could range from low to high intensity for individuals but of LOW intensity for the populations as a whole. As such impacts would be PROVINCIAL (although temporary in nature - a few minutes while the helicopter passes overhead) to the flight path and IMMEDIATE-TERM (1.5 months), impacts would be of VERY LOW consequence.

Impact Significance

Vessel Noise

The potential impact of vessel noise causing physiological injury to, or behavioural avoidance by, pelagic and coastal sensitive species, is deemed to be of VERY LOW significance.

Aircraft Noise

The potential impact of aircraft noise causing physiological injury to, or behavioural avoidance by, pelagic and coastal sensitive species, is deemed to be of LOW significance.

Identification of Mitigation Measures

Recommendations for mitigation include:

No	[illegible]	[illegible]
1	Pre-plan flight paths to ensure that no flying occurs over coastal seal colonies and seabird nesting areas	Avoid / abate on site
2	Avoid extensive low-altitude coastal flights by ensuring that the flight path is perpendicular to the coast, as far as possible	Avoid/ abate on site
3	Brief all pilots on the ecological risks associated with flying at a low level along the coast or above marine mammals	Avoid

Residual Impact Assessment

The generation of noise from helicopters cannot be eliminated if helicopters are required for crew changes. Similarly, the generation of vessel noise cannot be eliminated. The proposed mitigation, specifically maintaining the regulated altitude over the coastal zone and MPAs and flying perpendicular to the coast would reduce the intensity of the impact to very low, but the residual impact will remain of very low consequence and of LOW significance. Without mitigation measures for vessel noise, the residual impact of vessel noise would remain VERY LOW.

Aircraft and vessel noise would, however, likely contribute to the growing suite of cumulative acoustic impacts to marine fauna in the area, but assessing the population level consequences of multiple smaller and more localised stressors (see for example Booth *et al.* 2020; Derous *et al.* 2020) is difficult.

4.4.2 Impact of Survey Vessel Lighting on Pelagic Fauna

Source of Impact

The project activities that will result in an increase in noise impacts on marine fauna are listed below.

Mobilisation	Transit of vessels to survey area
Operation	Operation of survey vessel and support vessel
Demobilisation	Survey vessels leave survey area and transit to port or next destination

These activities and their associated aspects are described further below.

- Transit and operation of the survey vessel and support vessels. The operational lighting of survey/support vessels during transit and seismic acquisition can be a significant source of artificial light in the offshore environment increasing the ambient lighting in offshore areas.

Impact Description

The survey activities would be undertaken in the offshore marine environment, more than 100 km offshore, far removed from any sensitive coastal receptors (e.g. bird or seal colonies), but could still directly affect migratory pelagic species (pelagic seabirds, turtles, marine mammals and fish) transiting through the Reconnaissance Permit Area. The strong operational lighting used to illuminate the survey vessel at night may disturb and disorientate pelagic seabirds feeding in the area. Operational lights may also result in physiological and behavioural effects of fish and cephalopods as

these may be drawn to the lights at night where they may be more easily preyed upon by other fish and seabirds.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

The taxa most vulnerable to ambient lighting are pelagic seabirds, although turtles (particularly hatchlings and neonates), large migratory pelagic fish, and both migratory and resident cetaceans transiting through the survey area may also be attracted by the lights. Some of the species potentially occurring in the survey area, are considered regionally or globally 'Critically Endangered' (e.g. southern bluefin tuna, leatherback turtles and blue whales), 'Endangered' (e.g. Black-Browed and Yellow-Nosed Albatross, whale shark, shortfin mako shark, fin and sei whales), 'Vulnerable' (e.g. bigeye tuna, blue marlin, loggerhead turtles, oceanic whitetip shark, dusky shark, great white shark, longfin mako and sperm, Bryde's and humpback whales) or 'Near Threatened' (e.g. striped marlin, blue shark, longfin tuna/albacore and yellowfin tuna). Although species listed as 'Critically Endangered' or 'Endangered' may potentially occur in the survey area, due to their extensive distributions their numbers are expected to be low. Based on the low numbers of listed species, the sensitivity is considered to be **MEDIUM**.

Consequence of Impact

Although little can be done on the survey vessel to prevent seabird collisions, reports of collisions or death of seabirds on vessels are rare. Should they occur, the light impacts would primarily take place in the survey area and along the route taken by the support vessels between the survey area and Saldanha Bay/Cape Town. Most of the seabird species breeding along the West Coast feed relatively close inshore (10-30 km), with African Penguins recorded as far as 60 km offshore and Cape Gannets up to 140 km offshore. Pelagic species occurring further offshore would be unfamiliar with artificial lighting and may be attracted to the survey vessel. Fish and squid may also be attracted to the light sources potentially resulting in increased predation on these species by higher order consumers. It is expected, however, that seabirds and marine mammals in the area would become accustomed to the presence of the survey vessel within a few days. Since the survey area is located within the main traffic routes that pass around southern Africa, which experience high vessel traffic, animals in the area should be accustomed to vessel traffic.

Operational lights may also result in physiological and behavioural effects of turtles fish and cephalopods, as these may be drawn to the lights at night where they may be more easily preyed upon by other fish, marine mammals and seabirds. The dispersal of turtle hatchlings is reported to be disrupted by light, causing them to linger, become disoriented in the nearshore and expend energy swimming against ocean currents (Wilson *et al.* 2018). Although seals are known to forage up to 120 nautical miles (~220 km) offshore, the offshore location of the proposed survey area fall to the west of the foraging range of seals from the West Coast colonies. Odontocetes are also highly mobile, supporting the notion that various species are likely to occur in the Reconnaissance Permit Area and thus potentially attracted to the area.

625

Due to their extensive distributions, the numbers of pelagic species (large pelagic fish, turtles and cetaceans) encountered during the proposed 3D survey is expected to be low. Due to anticipated numbers and the proximity of survey area to the main traffic routes, the increase in ambient lighting in the offshore environment would be of LOW intensity and REGIONAL in extent (although limited to the area in the immediate vicinity of the vessel) over the IMMEDIATE-TERM (1.5 months). For support vessels travelling from Saldanha Bay/Cape Town increase in ambient lighting would likewise be restricted to the immediate vicinity of the vessel over the short-term. The potential for behavioural disturbance as a result of vessel lighting would thus be of VERY LOW consequence.

Impact Significance

The potential for collision of birds with the survey vessel due to lighting or behavioural disturbance by vessel lighting is deemed to be of VERY LOW significance, due to the medium sensitivity of the receptors, the low likelihood of the impact occurring and the very low consequence.

Identification of Mitigation Measures

The use of lighting on the seismic vessel cannot be eliminated due to safety, navigational and operational requirements. Recommendations for mitigation include:

No		
1	The lighting on the survey and support vessels should be reduced to a minimum compatible with safe operations whenever and wherever possible. Light sources should, if possible and consistent with safe working practices, be positioned in places where emissions to the surrounding environment can be minimised	Reduce at Source
2	Keep disorientated, but otherwise unharmed, seabirds in dark containers for subsequent release during daylight hours. Ringed/banded birds should be reported to the appropriate ringing/banding scheme (details are provided on the ring)	Repair or Restore

Residual Impact Assessment

With the implementation of the mitigation measures above, the residual impact would remain VERY LOW.

4.4.3 Impact of Hull Fouling and Ballast Water Discharge

Source of Impact

The project activities that will result in the discharge of ballast water and potential introduction of alien invasive species are listed below.

Project phase	Activity
Mobilisation	Transit of vessels to survey area
	Discharge of ballast water by seismic vessel and/or support vessels
Operation	n/a
Demobilisation	n/a

These activities and their associated aspects are described further below:

- Larvae, cysts, eggs and adult marine organisms are frequently firmly attached to artificial structures such as vessel hulls and infrastructure that have been in the sea for any length of time. Vessels and the transportation of infrastructure from one place to another in the ocean also provide the potential for translocation of introduced or alien species.
- De-ballasting of the survey vessel once at the survey area could introduce non-native species into the area.

Impact Description

Artificial structures deployed at sea serve as a substrate for a wide variety of larvae, cysts, eggs and adult marine organisms. The transportation of equipment from one part of the ocean to another would therefore also facilitate the transfer of the associated marine organisms. Survey vessels, seismic equipment and support vessels are used and relocated all around the world. Similarly, the ballasting and de-ballasting of these vessels may lead to the introduction of exotic species and harmful aquatic pathogens to the marine ecosystems (Bax *et al.* 2003).

The marine invertebrates that colonize the surface of vessels can easily be introduced to a new region, where they may become invasive by outcompeting and displacing native species. Marine invasive species are considered primary drivers of ecological change in that they create and modify habitat, consume and outcompete native fauna, act as disease agents or vectors, and threaten biodiversity. Once established, an invasive species is likely to remain in perpetuity (Bax *et al.* 2003).

Project Controls

5208

Ballast water is discharged subject to the requirements of the International Maritime Organisation's (IMO) 2004 International Convention for the Control and Management of Ships' Ballast Water and Sediments. The Convention aims to prevent the spread of harmful aquatic organisms from one region to another, by establishing standards and procedures for the management and control of ships' ballast water and sediments. The Convention stipulates that all ships are required to implement a Ballast Water Management Plan and that all ships using ballast water exchange will do so at least 200 nautical miles from nearest land in waters of at least 200 m deep; the absolute minimum being 50 nautical miles from the nearest land. Project vessels would be required to comply with this requirement.

Sensitivity of Receptors

The discharge of ballast water from the survey and support vessels would take place in the vicinity of the survey area, which is located more than 40 km offshore, far removed from any sensitive coastal receptors (e.g. sessile benthic invertebrates, endemic neritic and demersal fish species). In addition, due to the water depths in the survey area (~500 m up to nearly 4 000 m), colonisation by invasive species on the seabed is considered unlikely. Thus, the sensitivity of benthic receptors in the offshore waters of the Orange Basin is therefore considered VERY LOW.

Consequence of Impact

The most important pathways in the transfer of marine alien species have always been related to shipping (Hewitt *et al.* 1999; Ruiz *et al.* 2000; Ruiz & Carlton 2003), with primary introduction events arising mainly from ships moving between major international ports and secondary local spread occurring via regional vessels (Wasson *et al.* 2001; Lacoursière-Roussel *et al.* 2012).

The principal vectors responsible for transfer of alien invasive species are ballast water and external hull fouling (Carlton 1987, 1999; Hewitt *et al.* 2009). Following the prohibition of harmful organotins, such as tributyltin (TBT), in anti-fouling paints (IMO 2001), hull fouling remains responsible for a large proportion of current alien introductions. More than half of the recognised marine alien species in the United Kingdom have been associated with shipping, with the main vector being fouling (Eno 1996), with Australia demonstrating a similar pattern (Thresher 1999).

In South Africa the first review of marine alien species was published in 1992, and listed 15 introduced species (Griffiths *et al.* 1992). This number has grown rapidly since with the National Biodiversity Assessment (Sink *et al.* 2019) reporting 96 introduced marine species including 55 that are considered to be invasive. Invasive species were more prevalent on rocky shores than in other broad ecosystem group, and in the Southern Benguela than in other ecoregions. Shipping activity has been responsible for 86% of these marine introductions, 48% of which are due to fouling (Mead *et al.* 2011).

Alien species have the potential to displace native species, cause the loss of native genotypes, modify habitats, change community structure, affect food web properties and ecosystem processes, impede the provision of ecosystem services, impact human health and cause substantial economic losses (Katsanevakis *et al.* 2014).

The survey vessel, and possibly the support / escort vessels, will more than likely have spent time outside of South Africa's EEZ prior to surveying. This exposure to foreign water bodies and possible loading of ballast water increases the risk of introducing invasive or non-indigenous species into South African waters. The risk of this impact is, however, significantly reduced due by the implementation of ballast water management measures in accordance with the IMO guidelines. The risk is further

JE28

reduced due to the far offshore location of the survey area. Since the survey area is far removed from the coast, which together with the dominant wind and current direction, will ensure that any invasive species drift mainly in a north-westerly direction away from the coast. In addition, the water depths in the survey area (~500 m up to nearly 4 000 m) will ensure that colonisation of invasive species on the seabed is unlikely. De-ballasting in the survey area will thus not pose an additional risk to the introduction of invasive species.

In terms of hull fouling, the survey area is located along one of the main traffic routes that pass around southern Africa. Thus, the introduction of invasive species into South African waters due to hull fouling of project vessels is unlikely to add to the current risk that exists due to the numerous vessels that operate in or pass through South African coastal waters, through and inshore of the survey area, on a daily basis.

Considering the location of the survey area and compliance with the IMO guidelines for ballast water, the impact related to the introduction of alien invasive marine species is considered to be of MEDIUM intensity (due to it having a minimal effect on receptors) in the IMMEDIATE-TERM (due to invasive species not able to establish) and of REGIONAL extent. Thus, the consequence is, therefore, considered to be LOW.

Impact Significance

The potential for introductions of non-native marine species through hull fouling or ballast water discharge is deemed to be VERY LOW, due to the very low sensitivity of the offshore receptors, the low likelihood of the impact occurring and the low consequence.

Identification of Mitigation Measures

This potential impact cannot be eliminated due to the necessity of bringing survey vessels and seismic equipment to the survey area from other parts of the world, and the need for de-ballasting these once on site. In addition to the Project Controls, recommendations for mitigation include:

No.	Mitigation recommended	Type of mitigation
1	Avoid the unnecessary discharge of ballast water.	Reduce at source
2	Use filtration procedures during loading in order to avoid the uptake of potentially harmful aquatic organisms, pathogens and sediment that may contain such organisms	Avoid/reduce at source
3	Ensure that routine cleaning of ballast tanks to remove sediments is carried out, where practicable, in mid-ocean or under controlled arrangements in port or dry dock, in accordance with the provisions of the ship's Ballast Water Management Plan	Avoid/reduce at source
4	Ensure all infrastructure (e.g. arrays, streamers, tail buoys etc) that has been used in other regions is thoroughly cleaned prior to deployment	Avoid/Reduce at Source

Residual Impact Assessment

With the implementation of the mitigation measures above, the residual impact would reduce to NEGLIGIBLE.

4.4.4 Impacts of Waste Discharges to Sea

Source of Impact

The project activities that will result in a reduction of water quality from routine discharges to the sea from vessels are listed below.

Project phase	Activity
Mobilisation	Transit of vessels to survey area
Operation	Operation of survey vessels and transit of support vessels between the survey area and the logistics base
Demobilisation	Survey vessels leave survey area and transit to port or next destination

These activities and their associated aspects are described further below:

- Deck drainage: all deck drainage from work spaces is collected and piped into a sump tank on board the seismic vessel to ensure MARPOL compliance (15 ppm oil in water). The fluid would be analysed and any hydrocarbons skimmed off the top prior to discharge. The oily substances would be added to the waste (oil) lubricants and disposed of at a suitable facility onshore.
- Grey Water and Sewage: sewage discharges will be comminuted and disinfected. In accordance with MARPOL Annex IV, the effluent must not produce visible floating solids in, nor causes discolouration of, the surrounding water. The treatment system must provide primary settling, chlorination and dechlorination before the treated effluent can be discharged into the sea. The treated sanitary effluents discharged into the sea are estimated at around 10 000 litres per day for the duration of the seismic study based on 140-150 litres per 70-80 persons. The discharge depth is variable, depending upon the draught of the seismic vessel / support vessel at the time, but would be in accordance with MARPOL Annex IV.

1023

- **Vessel machinery spaces, mud pit wash residue and ballast water:** the concentration of oil in discharge water from vessel machinery space or ballast tanks may not exceed 15 ppm oil in water (MARPOL Annex I). If the vessel intends to discharge bilge or ballast water at sea, this is achieved through use of an oily-water separation system. Oily waste substances must be shipped to land for treatment and disposal.
- **Food (galley) wastes:** food wastes may be discharged after they have been passed through a comminuter or grinder, and when the seismic vessel is located more than 3 nautical miles from land. Discharge of food wastes not comminuted is permitted beyond 12 nautical miles. The ground wastes must be capable of passing through a screen with openings <25 mm. The daily volume of discharge from a standard seismic vessel is expected to be <0.2 m^3.
- **Cooling Water and drinking water surplus:** The cooling water and surplus generated by the drinking water supply system are likely to contain a residual concentration of chlorine (generally less than 0.5 mg/l for drinking water supply systems, seismic vesselSuch water would be tested prior to discharge and would comply with relevant Water Quality Guidelines.

Impact Description

The discharge of wastes to sea could create local reductions in water quality, both during transit to and within the survey area. Deck and machinery space drainage may result in small volumes of oils, detergents, lubricants and grease, the toxicity of which varies depending on their composition, being introduced into the marine environment. Sewage and gallery waste will place a small organic and bacterial loading on the marine environment, resulting in an increased biological oxygen demand.

These discharges will result in a local reduction in water quality, which could impact marine fauna in a number of different ways:

- Physiological effects: Ingestion of hydrocarbons, detergents and other waste could have adverse effects on marine fauna, which could ultimately result in mortality.
- Increased food source: The discharge of galley waste and sewage will result in an additional food source for opportunistic feeders, speciality pelagic fish species.
- Increased predator - prey interactions: Predatory species, such as sharks and pelagic seabirds, may be attracted to the aggregation of pelagic fish attracted by the increased food source.

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and in compliance with the applicable requirements in MARPOL 73/78, as summarised below.

- The discharge of biodegradable wastes from vessels is regulated by MARPOL 73/78 Annex V, which stipulates that:
  - No disposal to occur within 3 nm (± 5.5 km) of the coast.
  - Disposal between 3 nm (± 5.5 km) and 12 nm (± 22 km) needs to be comminuted to particle sizes smaller than 25 mm.
  - Disposal overboard without macerating can occur greater than 12 nm from the coast when the vessel is sailing.
- Discharges of oily water (deck drainage, bilge and mud pit wash residue) to the marine environment are regulated by MARPOL 73/78 Annex I, which stipulates that vessels must have:

  - A Shipboard Oil Pollution Emergency Plan (SOPEP).
  - A valid International Oil Pollution Prevention Certificate, as required by vessel class.
  - Equipment for the control of oil discharge from machinery space bilges and oil fuel tanks. e.g. oil separating/filtering equipment and oil content meter. Oil in water concentration must be less than 15 ppm prior to discharge overboard.
  - Oil residue holding tanks.
  - Oil discharge monitoring and control system.
- Sewage and grey water discharges from vessels are regulated by MARPOL 73/78 Annex IV, which specifies the following:
  - Vessels must have a valid International Sewage Pollution Prevention Certificate.
  - Vessels must have an onboard sewage treatment plant providing primary settling, chlorination and dechlorination before discharge of treated effluent.
  - The discharge depth is variable, depending upon the draught of the seismic vessel / support vessel at the time, but will be in accordance with MARPOL 73/78 Annex IV.
  - Discharge of sewage beyond 12 nm requires no treatment. However, sewage effluent must not produce visible floating solids in, nor cause the discolouration of, the surrounding water.
  - Sewage must be comminuted and disinfected for discharges between 3 nm (± 6 km) and 12 nm (± 22 km) from the coast. This will require an onboard sewage treatment plant or a sewage comminuting and disinfecting system.
  - Disposal of sewage originating from holding tanks must be discharged at a moderate rate while the ship is proceeding on route at a speed not less than 4 knots.
- Sewage will be treated using a marine sanitation device to produce an effluent with:
  - A biological oxygen demand (BOD) of <25 mg/l (if the treatment plant was installed after 1/1/2010) or <50 mg/l (if installed before this date).
  - Minimal residual chlorine concentration of 0.5 mg/l.
  - No visible floating solids or oil and grease.

The project will also comply with industry best practices with regard to waste management, including:

- Waste management will follow key principles: Avoidance of Waste Generation, adopting the Waste Management Hierarchy (reduce, reuse, recycle, recover, residue disposal), and use of Best Available Technology.
- An inventory will be established of all the potential waste generated, clarifying its classification (hazardous, non-hazardous or inert) and quantity, as well as identifying the adequate treatment and disposal methods.
- Waste collection and temporary storage shall be designed to minimise the risk of escape to the environment (for example by particulates, infiltration, runoff or odours).
- On-site waste storage should be limited in time and volume.
- Dedicated, clearly labelled, containers (bins, skips, etc.) will be provided in quantities adapted to anticipated waste streams and removal frequency.

Sensitivity of Receptors

The operational waste discharges from the activities described above would primarily take place in the survey area and along the route taken by the support vessels between the survey area and the logistics base in Saldanha Bay/Cape Town. The 3D survey area is located in the offshore marine environment, far removed from coastal MPAs and any sensitive coastal receptors (e.g. key faunal

breeding/feeding areas, bird or seal colonies and nursery areas for commercial fish stocks); however, discharges could still directly affect migratory pelagic species transiting through the survey area. Vessel discharges *en route* to the onshore supply base could result in discharges closer to shore, thereby potentially having an environmental effect on the sensitive coastal environment.

The taxa most vulnerable to waste discharges are pelagic seabirds, turtles, and large migratory pelagic fish and marine mammals. Some of of the species potentially occurring in the survey area, are considered regionally or globally 'Critically Endangered' (e.g. southern bluefin tuna, leatherback turtles and blue whales), 'Endangered' (e.g. Black-Browed and Yellow-Nosed Albatross, whale shark, shortfin mako shark, fin and sei whales), 'Vulnerable' (e.g. bigeye tuna, blue marlin, loggerhead turtles, oceanic whitetip shark, dusky shark, great white shark, longfin mako and sperm, Bryde's and humpback whales) or 'Near Threatened' (e.g. striped marlin, blue shark, longfin tuna/albacore and yellowfin tuna). Although species listed as 'Critically Endangered' or 'Endangered' may potentially occur in the survey area, due to their extensive distributions their numbers are expected to be low. Based on the low numbers of listed species, the sensitivity is considered to be **MEDIUM.**

Consequence of Impact

The contracted survey / support vessels will have the necessary sewage treatment systems in place, and the vessel will have oil/water separators and food waste macerators to ensure compliance with MARPOL 73/78 standards. MARPOL compliant discharges would therefore introduce relatively small amounts of nutrients and organic material to oxygenated surface waters, which will result in a minor contribution to local marine productivity and possibly of attracting opportunistic feeders. The intermittent discharge of sewage is likely to contain a low level of residual chlorine following treatment, but given the relatively low total discharge and rapid dilution in surface waters this is expected to have a minimal effect on seawater quality.

Furthermore the survey area is suitably far removed from sensitive coastal receptors and the dominant wind and current direction will ensure that any discharges are rapidly dispersed north-westwards and away from the coast. There is no potential for accumulation of wastes leading to any detectable long-term impact.

Due to the distance offshore, it is only pelagic fish, birds, turtles and cetaceans that may be affected by the discharges, and these are unlikely to respond to the minor changes in water quality resulting from vessel discharges. The most likely animal to be attracted to the survey vessels will be large pelagic fish species, such as the highly migratory tuna and billfish, as well as sharks and odontocetes (toothed whales). Pelagic seabirds that feed primarily by scavenging would also be attracted.

Other types of wastes generated during the exploration activities will be segregated, duly identified transported to shore for ultimate valorisation and/or disposal at a licensed waste management facility. The disposal of all waste onshore will be fully traceable.

Based on the relatively small discharge volumes and compliance with MARPOL 73/78 standards, offshore location and high energy sea conditions, the potential impact of normal discharges from the survey / support vessels will be of VERY LOW intensity, IMMEDIATE duration and REGIONAL in extent (although localised at any one time around the project vessels). The impact consequence is therefore considered VERY LOW.

Impact Significance

The impacts associated with normal waste discharges from the survey vessel is deemed to be of VERY LOW significance, due to the medium sensitivity of the offshore receptors, the medium probability of the impact occurring and the very low consequence.

Identification of Mitigation Measures

In addition to compliance with MARPOL 73/78 regulations regarding waste discharges mentioned above, the following measures will be implemented to reduce wastes at the source:

No.	Mitigation measure	Classification
1	Implement leak detection and repair programmes for valves, flanges, fittings, seals, etc.	Avoid/Reduce at Source
2	Use a low-toxicity biodegradable detergent for the cleaning of all deck spillages.	Reduce at Source

Residual Impact Assessment

This potential impact cannot be eliminated because the seismic / support vessels are needed to undertake the survey and will generate routine discharges during operations. With the implementation of the project controls and mitigation measures, the residual impact will remain of VERY LOW significance.

4.5 Unplanned Events

4.5.1 Faunal Strikes with Project Vessels and Equipment

Source of Impact

The project activities that will result in potential collision impacts with marine fauna are listed below.

Project phase	Activity
Mobilisation	Ship strikes during transit of vessels to survey area
Operation	Ship strikes during Operation of survey vessels
	Strikes and entanglement of marine fauna during seismic and/or acquisition
Demobilisation	Ship strikes during transit to port or next destination

These activities and their associated aspects are described below:

- Passage of the seismic vessel and chase vessels - Ship strikes.
- Towing of seismic equipment - Collision with or entanglement in towed seismic apparatus.

Impact Description

The potential effects of vessel presence and towed equipment on turtles and cetaceans include physiological injury or mortality.

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

The leatherback and loggerhead turtles that occur in offshore waters around southern Africa, and likely to be encountered in the proposed survey area are considered regionally 'Critically Endangered' and 'Near Threatened', respectively. However, due to their extensive distributions and feeding ranges, the numbers of individuals encountered during the survey are likely to be low. Consequently, the sensitivity of turtles is considered to be **MEDIUM**.

Thirty three species or sub species/populations of cetaceans (whales and dolphins) are known or likely to occur off the West Coast. The majority of migratory cetaceans in South African waters are baleen whales (mysticetes), while toothed whales (odontocetes) may be resident or migratory. Of the 33 species, the blue whale is listed as 'Critically Endangered', the fin and sei whales are 'Endangered' and the sperm, Bryde's (offshore) and humpback whales are considered 'Vulnerable' (South African Red Data list Categories). Although the survey area is far removed from the coast, overlap with Child's Bank and the proximity to Tripp Seamount, where a greater number of individuals can be expected, the sensitivity of cetaceans to strikes is considered to be **HIGH**.

Consequence of Impact

Ship strikes are globally the biggest threat to large whales, having direct, long-term and population-level consequences (Schoeman *et al.* 2020). Although most scientific publications to date have

focussed on collisions between vessel and whales and manatees, there is growing evidence that at least 75 marine species, including smaller whales, dolphins, porpoises, dugongs, manatees, whale sharks, sharks, seals, sea otters, turtles, penguins, and fish are at risk of collision, especially within coastal areas frequented by smaller vessels (reviewed by Schoeman *et al.* 2020). As the proposed 3D survey area is located in a region of very high vessel traffic (see Figure 46), potential collisions between marine fauna and vessels would not be limited to project-specific vessels. Given the slow speed (about 4 - 6 kts) of the vessel while towing the seismic array, ship strikes whilst surveying are unlikely, but may occur during the transit of the vessel to or from the survey area. Ship strikes by the chase vessel may also occur.

The physical presence of the survey vessel and increased vessel traffic west of the main transport routes could increase the likelihood of animal-vessel collisions. Ship strikes have been reported to result in medium-term effects such as evasive behaviour by animals experiencing stress, or longer-term effects such as decreased fitness or habitual avoidance of areas where disturbance is common and in the worst case death (see for example Constantine 2001; Hastie *et al.* 2003; Lusseau 2004, 2005; Bejder *et al.* 2006; Lusseau *et al.* 2009). Ship strikes have been documented from many regions and for numerous species of whales (Panigada *et al.* 2006; Douglas *et al.* 2008; Elvin & Taggart 2008) and dolphins (Bloom & Jager 1994; Elwen & Leeney 2010), with large baleen whales being particularly susceptible to collision (Pirotta *et al.* 2019). Any increase in vessel traffic through areas used as calving grounds or through which these species migrate will increase the risk of collision between a whale and a vessel.

The potential for ship strikes of cetaceans is dependent on the abundance and behaviour of cetaceans in the area and vessel speed. For example, Keen *et al.* (2019) modeled fin whale ship strike risk in the California Current System and found that night-time collision risk was twice as high as the daytime risk. Due to their extensive distributions and feeding ranges, the number of cetaceans encountered by project vessels in the offshore environment is expected to be low.

The large amount of equipment towed astern of survey vessels also increases the potential for collision with or entrapped in seismic equipment and towed surface floats. Entanglement of cetaceans in gear is possible in situations where tension is lost on the towed array.

Basking turtles are particularly slow to react to approaching objects and may not be able to move rapidly away from approaching airguns. In the past, almost all reported turtle entrapments were associated with the subsurface structures ("undercarriage") of the tail buoys attached to the end of each seismic cable. Towing points are located on the leading edge of each side of the undercarriage, and these are attached by chains to a swivel leading to the end of the seismic cable (Ketos Ecology 2009). Entrapment occurs either as a result of 'startle diving' in front of towed equipment or following foraging on barnacles and other organisms growing along seismic cables and surfacing to breathe immediately in front of the tail buoy (primarily loggerhead and Olive Ridley turtles). In the first case the turtle becomes stuck within the angled gap between the chains and the underside of the buoy, lying on their sides across the top of the chains and underneath the float with their ventral surface facing the oncoming water thereby causing the turtle to be held firmly in position (Figure 49, left). Depending on the size of the turtle, they can also become stuck within the gap below a tail buoy, which extends to 0.8 m below water level and is ~0.6 m wide. The animal would need to be small enough to enter the gap, but too big to pass all the way through the undercarriage. Furthermore, the presence of the propeller in the undercarriage of some buoy-designs prohibits turtles that have entered the undercarriage from travelling out of the trailing end of the buoy (Figure 49, right). Once

8228

stuck inside or in front of a tail buoy, the water pressure generated by the 4-6 knot towing speed, would hold the animal against/inside the buoy with little chance of escape due to the angle of its body in relation to the forward movement of the buoy. For a trapped turtle this situation will be fatal, as it will be unable to reach the surface to breathe (Ketos Ecology 2009). To prevent entrapment, the seismic industry has implemented the use of "turtle guards" on all tailbuoys.

The potential for collision between adult turtles and the seismic vessel, or entanglement of turtles in the towed seismic equipment and surface floats, is highly dependent on the abundance and behaviour of turtles in the survey area at the time of the survey. Due to their extensive distributions and feeding ranges, and the extended distance from their nesting sites, the number of turtles encountered during the proposed seismic surveys is expected to be low. Should collisions or entanglements occur, the impacts would be of high intensity for individuals but of LOW intensity for the population as a whole. Furthermore, as the duration of the impact would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL), the potential for collision and entanglement in seismic equipment is therefore considered to be of VERY LOW consequence.

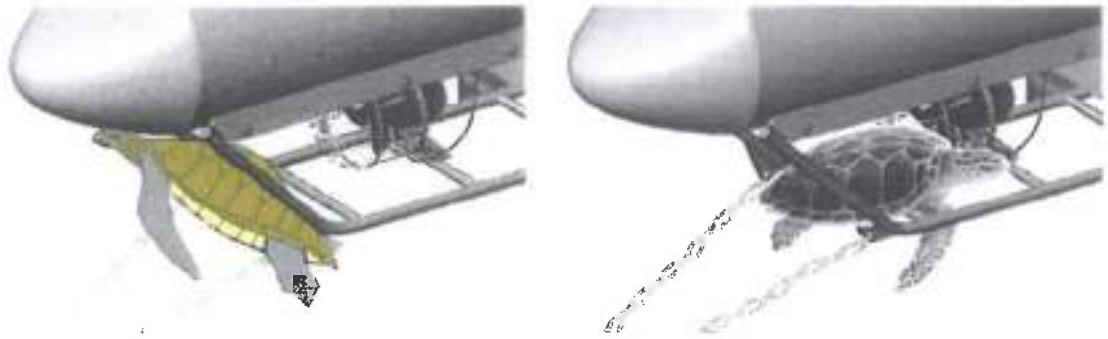

Figure 49: Turtles commonly become trapped in front of the undercarriage of the tail buoy in the area between the buoy and the towing chains (left), and inside the 'twin-fin' undercarriage structure (right) (Ketos Ecology 2009).

The potential for strikes and entanglement of cetaceans in the towed seismic equipment, is similarly highly dependent on the abundance and behaviour of cetaceans in the survey area at the time of the survey. Due to their extensive distributions and feeding ranges, the number of cetaceans encountered during the proposed seismic surveys is expected to be low. Should entanglements occur, the impacts would be of high intensity for individuals but of LOW intensity for the population as a whole. Furthermore, as the duration of the impact would be limited to the IMMEDIATE-TERM (1.5 months) and be restricted to the survey area (REGIONAL), the potential for entanglement in seismic equipment is therefore considered to be of VERY LOW consequence.

Impact Significance

The potential for collision with or entanglement by turtles and cetaceans during the seismic survey or the transit of the vessel to or from the survey area is deemed to be of LOW significance, due to the high sensitivity of the receptors, but very low likelihood of the impact occurring and the low consequence.

Recommendations for mitigation include:

528

No	Mitigation measure	Implementation
1	The vessel operators should keep a constant watch for marine mammals and turtles in the path of the vessel.	Avoid
2	Keep watch for marine mammals behind the vessel when tension is lost on the towed equipment and either retrieve or regain tension on towed gear as rapidly as possible.	Avoid
3	Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector turtle guards'.	Abate on site
4	Ensure vessel transit speed between the survey area and port is a maximum of 12 knots (22 km/hr), except in MPAs where it is reduced further to 10 knots (18 km/hr) as well as when they are present in the vicinity.	Avoid/reduce at source

Monitoring

Should a collision with a large whale occur, the event must be reported to the IWC database, which has been shown to be a valuable tool for identifying the species most affected, vessels involved in collisions, and correlations between vessel speed and collision risk (Jensen & Silber 2003).

Residual Impact Assessment

With the implementation of the mitigation measures above, the residual impact would remain LOW.

4.5.2 Accidental Loss of Equipment

Source of Impact

The project activities that will result in the accidental loss of equipment are listed below.

Project phase	Activity
Mobilisation	n/a
Operation	Accidental loss of equipment to the water column or seabed during operation
Demobilisation	n/a

These activities and their associated aspects are described further below:

- Irretrievable loss of equipment to the seabed during vessel transfer with crane.
- Accidental loss of paravanes, streamers, arrays and tail buoys during seismic acquisition.

During seismic acquisition, the survey vessel tows a substantial amount of equipment; the deflectors or paravanes, which keep the streamers equally spread are towed by heavy-duty rope, and the streamers themselves are towed by lead-in cables. Each streamer is fitted with a dilt float at the head of the streamer, numerous streamer mounts (birds and fins) to control streamer depth and lateral positioning, and a tail buoy to mark the end of the streamer. Streamers are neutrally buoyant at the required depth (5-10 m) but have buoyancy bags embedded within them that inflate at a depth of 40 m. If streamers are accidentally lost they would therefore float in the water column for some time before sinking. Dilt floats and tail buoys would ultimately be dragged down under the weight of the streamer.

Airguns are suspended under floats by a network of ropes, cables and chains, with each float configuration towed by an umbilical. Should both the float and umbilical fail, the airguns would sink to the seabed.

In the unlikely event of complete failure of buoyancy and tow systems, the seismic equipment and the attached ropes, cables and chains could pose an entanglement hazard to turtles and marine mammals.

If equipment falls to the seabed, it would crush benthic fauna in its footprint, but ultimately provide a hard surface for colonisation.

Impact Description

The potential impacts associated with lost equipment include:

- Potential disturbance and damage to seabed habitats and crushing of epifauna and infauna within the equipment footprint;
- Potential physiological injury or mortality to pelagic and neritic marine fauna due to entanglement in streamers, arrays and tail buoys drifting on the surface or in the water column.

Project Controls

The seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques.

Sensitivity of Receptors

Loss of equipment would likely take place during seismic acquisition within the survey area, which is located in the offshore marine environment, more than 40 km offshore at its closest point, far removed from any sensitive coastal receptors (e.g. key faunal breeding/feeding areas, bird or seal colonies and nursery areas for commercial fish stocks). The survey area lies well offshore where the pelagic and benthic ecosystem threat status is mainly considered as 'Least threatened', and where the deepwater habitat types are comparatively uniform and cover large areas. The benthic fauna beyond ~450 m depth are very poorly known and there are no species of commercial value occurring that far offshore. Sensitive deep-water coral communities would be expected with topographic features such as Tripp Seamount and Child's Bank. The sensitivity of benthic fauna is considered to be LOW.

Lost equipment could also pose an entanglement risk to migratory turtles and cetaceans transiting through the survey area. The taxa most vulnerable to entanglement in lost equipment are turtles and marine mammals. Some of the species potentially occurring in the survey area, are considered regionally or globally 'Critically Endangered' (e.g. leatherback turtles and blue whales), 'Endangered' (e.g. whale shark, fin and sei whales), or 'Vulnerable' (e.g. loggerhead turtles and sperm, Bryde's and humpback whales). Although species listed as 'Critically Endangered' or 'Endangered' may potentially occur in the survey area, entanglement is highly unlikely. In addition, due to their extensive distributions their numbers are expected to be low. Based on the low numbers of listed species, the sensitivity is considered to be MEDIUM.

Overall, considering the precautionary principle, the sensitivity of marine fauna for collision or entanglement is considered to be MEDIUM.

Consequence of Impact

The accidental loss of equipment onto the seafloor would provide a localised area of hard substrate in an area of otherwise unconsolidated sediments. The availability of hard substrata on the seabed provides opportunity for colonisation by sessile benthic organisms and could provide shelter for demersal fish and mobile invertebrates thereby potentially increasing the benthic biodiversity and biomass in the continental slope and abyssal regions. The benthic fauna inhabiting islands of hard substrata in otherwise unconsolidated sediments of the outer shelf and continental slope are, however, very poorly known but would likely be different from those of the surrounding

3428

unconsolidated sediments. In the unlikely event of equipment loss, associated impacts would be of LOW intensity and be highly localised and limited to the SITE over the IMMEDIATE-term (any lost object, depending on its size, will likely sink into the sediments and be buried over time). The impact consequence for equipment lost to the seabed is therefore considered VERY LOW.

The loss of streamers and floats would result in entanglement hazards in the water column before the streamers sink under their own weight. In the unlikely event of streamer loss, associated impacts would similarly be of LOW intensity and be highly localised and limited to the SITE (although would potentially float around regionally) over the IMMEDIATE-term. The impact consequence for equipment lost to the water column is therefore considered VERY LOW.

Impact Significance

The impacts associated with the accidental loss of equipment are deemed to be of VERY LOW significance, due to the medium sensitivity of the offshore receptors, the very low likelihood of the impact occurring and the very low consequence.

Identification of Mitigation Measures

The following measures will be implemented to manage accidental loss of equipment:

No.	Mitigation measure	Classification
1	Ensuring that loads are lifted using the correct lifting procedure and within the maximum lifting capacity of crane system.	Avoid
2	Minimise the lifting path between vessels.	Avoid
3	Undertake frequent checks to ensure items and equipment are stored and secured safely on board each vessel.	Avoid
4	In the event that equipment is lost during the operational stage, assess safety and metocean conditions before performing any retrieval operations. Establishing a hazards database listing the type of gear left on the seabed and/or in the Reconnaissance Permit Area with the dates of abandonment/loss and locations, and where applicable, the dates of retrieval	Repair/restore

Residual Impact Assessment

With the implementation of the project controls and mitigation measures, the residual impact will remain of VERY LOW significance

4.5.3 Release of diesel to sea during bunkering or due to vessel accident

Source of Impact

The project activities that will result in the accidental release of diesel / oil are listed below.

[illegible]	[illegible]
Mobilisation	Loss of fuel from vessel accident
Operation	Loss of fuel from vessel accident
	Bunkering of fuel
Demobilisation	Loss of fuel from vessel accident

These activities and their associated aspects are described further below:

- Instantaneous spills of marine diesel at the surface of the sea can potentially occur during operation, and Such spills are usually of a low volume.
- Larger volume spills of marine diesel would occur in the event of a vessel collision or vessel accident.

Impact Description

Marine diesel spilled in the marine environment would have an immediate detrimental effect on water quality, with the toxic effects potentially resulting in mortality (e.g. suffocation and poisoning) of

marine fauna or affecting faunal health (e.g. respiratory damage). If the spill reaches the coast, it can result in the smothering of sensitive coastal habitats.

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques. The purpose of the Operator's performance standards is to reduce the risk of pollution and oil spills for projects to As Low As Reasonably Practicable (ALARP). The objectives of the Operator's policies and procedures are to:

- Apply the hazard management process;
- Careful HSSE management by all parties;
- Design and install equipment and/or implement Procedures to reduce the impact of discharges to the environment;
- Assess the Maritime Safety Risks and put controls in place to manage these risks to ALARP;
- Establish and maintain procedures for managing the risk of maritime operations that comply with the Operator's Maritime Safety Requirements for Design, Engineering and Operation..

Escort vessels with appropriate radar and communications will be used during the survey operation to warn vessels that are in danger of breaching the safety/exclusion zone.

Regulation 37 of MARPOL Annex I will be applied, which requires that all ships of 400 gross tonnage and above carry an approved Shipboard Oil Pollution Emergency Plan (SOPEP). The purpose of a SOPEP is to assist personnel in dealing with unexpected discharge of oil, to set in motion the necessary actions to stop or minimise the discharge, and to mitigate its effects on the marine environment.

As standard practice, an Emergency Response Plan (ERP) / Evacuation Plan will be prepared and put in place. A Medical Evacuation Plan (Medevac Plan) will form part of the ERP.

Project vessels will be equipped with appropriate spill containment and clean-up equipment, e.g. booms, dispersants and absorbent materials. All relevant vessel crews will be trained in spill clean-up equipment use and routine spill clean-up exercises.

Sensitivity of Receptors

Accidental spills and loss of marine diesel during bunkering or in the event of a vessel collision could take place in the survey area and along the route taken by the survey and support vessels between the survey area and the logistics base at Saldanha Bay or Cape Town. The survey area is located in the offshore marine environment, more than 100 km offshore at its closest point, far removed from coastal MPAs and any sensitive coastal receptors (e.g. key faunal breeding/feeding areas, bird or seal colonies and nursery areas for commercial fish stocks); however, discharges could still directly affect migratory pelagic species transiting through the survey area. Diesel spills or accidents en route to the onshore supply base could result in fuel loss closer to shore, thereby potentially having Oil or diesel spilled in the marine environment will have an immediate detrimental effect on water quality. Being highly toxic, marine diesel released during an operational spill would negatively affect any marine fauna it comes into contact with. The taxa most vulnerable to hydrocarbon spills are coastal and pelagic seabirds. Some of the species potentially occurring in the survey area, are considered regionally or globally 'Critically Endangered' (e.g. Tristan Albatross, Cape Gannet) or 'Endangered' (e.g. Black-Browed and Yellow-Nosed Albatross, African Penguin, Bank and Cape Cormorant) or 'Vulnerable' (e.g. Hartlaub's Gull, Swift Tern). As Tripp Seamount is located ~25 km to the north of

the proposed 3D the survey area, the sensitivity of marine fauna to diesel spill is considered to be HIGH.

Consequence of Impact

Various factors determine the impacts of oil released into the marine environment. The physical properties and chemical composition of the oil, local weather and sea state conditions and currents greatly influence the transport and fate of the released product. The physical properties that affect the behaviour and persistence of an oil spilled at sea are specific gravity, distillation characteristics, viscosity and pour point, all of which are dependent on the oils chemical composition (e.g. the amount of asphaltenes, resins and waxes). Spilled oil undergoes physical and chemical changes (collectively termed 'weathering'), which in combination with its physical transport, determine the spatial extent of oil contamination and the degree to which the environment will be exposed to the toxic constituents of the released product.

As soon as oil is spilled, various weathering processes come into play. Although the individual processes may act simultaneously, their relative importance varies with time. Whereas spreading, evaporation, dispersion, emulsification and dissolution are most important during the early stages of a spill, the ultimate fate of oil is determined by the longer term processes of oxidation, sedimentation and biodegradation.

As a general rule, oils with a volatile nature, low specific gravity and low viscosity (e.g. marine diesel) are less persistent and tend to disappear rapidly from the sea surface. In contrast, high viscosity oils containing bituminous, waxy or asphaltenic residues, dissipate more slowly and are more persistent, usually requiring a clean-up response.

Oil spilled in the marine environment will have an immediate detrimental effect on water quality. Any release of liquid hydrocarbons thus has the potential for direct, indirect and cumulative effects on the marine environment. These effects include physical oiling and toxicity impacts to marine fauna and flora, localised mortality of plankton (particularly copepods), pelagic eggs and fish larvae, and habitat loss or contamination (CSIR 1998; Perry 2005).

The consequences and effects of small (2 000 - 20 000 litres) diesel fuel spills into the marine environment are summarised below (NOAA 1998). Diesel is a light oil that, when spilled on water, spreads very quickly to a thin film and evaporates or naturally disperses within a few days or less, even in cold water. Diesel oil can be physically mixed into the water column by wave action, where it adheres to fine-grained suspended sediments, which can subsequently settle out on the seafloor. As it is not very sticky or viscous, diesel tends to penetrate porous sediments quickly, but also to be washed off quickly by waves and tidal flushing. In the case of a coastal spill, shoreline cleanup is thus usually not needed. Diesel oil is degraded by naturally occurring microbes within one to two months. Nonetheless, in terms of toxicity to marine organisms, diesel is considered to be one of the most acutely toxic oil types. Many of the compounds in petroleum products are known to smother organisms, lower fertility and cause disease. Intertidal invertebrates and seaweed that come in direct contact with a diesel spill may be killed. Fish kills, however, have never been reported for small spills in open water as the diesel dilutes so rapidly. Due to differential uptake and elimination rates, filter-feeders (particularly mussels) can bio-accumulate hydrocarbon contaminants. Crabs and shellfish can be tainted from small diesel spills in shallow, nearshore areas.

Chronic and acute oil pollution is a significant threat to both pelagic and inshore seabirds. Diving sea birds that spend most of their time on the surface of the water are particularly likely to encounter

floating oil and will die as a result of even moderate oiling which damages plumage and eyes. The majority of associated deaths are as a result of the properties of the oil and damage to the water repellent properties of the birds' plumage. This allows water to penetrate the plumage, decreasing buoyancy and leading to sinking and drowning. In addition, thermal insulation capacity is reduced requiring greater use of energy to combat cold.

Impacts of oil spills on turtles are thought to primarily affect hatchling survival (CSIR & CIME 2011). Turtles encountered in the project area would mainly be migrating adults and vagrants. Similarly, little work has been done on the effect of an oil spill on fur seals.

The effects of oil pollution on marine mammals is poorly understood (White *et al.* 2001), with the most likely immediate impact of an oil spill on cetaceans being the risk of inhalation of volatile, toxic benzene fractions when the oil slick is fresh and unweathered (Geraci & St Aubin 1990, cited in Scholz *et al.* 1992). Common effects attributable to the inhalation of such compounds include absorption into the circulatory system and mild irritation to permanent damage to sensitive tissues such as membranes of eyes, mouth and respiratory tract. Direct oiling of cetaceans is not considered a serious risk to the thermoregulatory capabilities, as cetacean skin is thought to contain a resistant dermal shield that acts as a barrier to the toxic substances in oil. Baleen whales may experience fouling of the baleen plates, resulting in temporary obstruction of the flow of water between the plates and, consequently, reduce feeding efficiency. Field observations record few, if any, adverse effects among cetaceans from direct contact with oil, and some species have been recorded swimming, feeding and surfacing amongst heavy concentrations of oil (Scholz *et al.* 1992) with no apparent effects.

In the unlikely event of an operational spill or vessel collision, the magnitude of the impact would depend on whether the spill occurred in offshore waters where encounters with pelagic seabirds, turtles and marine mammals would be low due to their extensive distribution ranges, or whether the spill occurred closer to the shore where encounters with sensitive receptors will be higher. Based on the results of the oil spill modelling undertaken in the Orange Basin (PRDW 2013) a diesel slick in the survey area would be blown in a north-westerly direction due to the dominant winds and currents in the survey area. The diesel would most likely remain at the surface for <36 hours with no probability of reaching sensitive coastal habitats. In offshore environments, impacts associated with a spill or vessel collision would thus be of LOW intensity, REGIONAL (depending on the nature of the spill) over the IMMEDIATE-term (<5 days). The impact consequence for a marine diesel spill is therefore considered VERY LOW.

However, in the case of a spill or vessel collision en route to the survey area, the spill may extend into coastal MPAs and reach the shore affecting intertidal and shallow subtidal benthos and sensitive coastal bird species, in which case the intensity would be considered HIGH, but still remaining REGIONAL over the IMMEDIATE-TERM. The magnitude would however remain MEDIUM.

Impact Significance

The impact methodology used to assess the impact significance calculates an overall LOW pre-mitigation significance. However, considering the high sensitivity of receptors and the very low (offshore) and medium consequence (nearshore), the potential impact on the marine fauna is in reality considered to range from LOW significance (offshore) to MEDIUM significance (nearshore) without mitigation. The likelihood of the impact occurring is, however, low.

Identification of Mitigation Measures

In addition to compliance with MARPOL 73/78 regulations regarding waste discharges mentioned above, the following measures will be implemented:

No.	Mitigation measure	Objective
1	Use low toxicity dispersants cautiously and only with the permission of DFFE.	Abate on and off site
2	As far as possible, and whenever the sea state permits, attempt to control and contain the spill at sea with suitable recovery techniques to reduce the spatial and temporal impact of the spill	Abate on site
3	Ensure adequate resources are provided to collect and transport oiled birds to a cleaning station.	Restore
4	Ensure offshore bunkering is not undertake in the following circumstances: – Wind force and sea state conditions of ≥6 on the Beaufort Wind Scale; – During any workboat or mobilisation boat operations; – During helicopter operations; – During the transfer of in-sea equipment; and – At night or times of low visibility.	Avoid / Reduce at source

Residual Impact Assessment

With the implementation of the project controls and mitigation measures, the residual impact will reduce to LOW significance for nearshore spills, and remain LOW for offshore spills.

4.6 Confounding Effects and Cumulative Impacts

Cumulative effects are the combined potential impacts from different actions that result in a significant change larger than the sum of all the impacts. Consideration of 'cumulative impact' should

include "past, present and reasonably foreseeable future developments or impacts". This requires a holistic view, interpretation and analysis of the biophysical, social and economic systems (DEAT 2004).

Cumulative impact assessment is limited and constrained by the method used for identifying and analysing cumulative effects. As it is not practical to analyse the cumulative effects of an action on every environmental receptor, the list of environmental effects being considered to inform decision makers and stakeholders should focus on those that can be meaningfully interpretted (DEAT 2004).

While it is foreseeable that further exploration and future production activities could arise if the current Environmental Authorisation is granted, there is not currently sufficient information available to make reasonable assertions as to nature of such future activities. This is primarily due to the current lack of relevant geological information, which the proposed exploration process aims to address. There are many other rights holders in the South African and adjacent Namibian offshore environment, but most of these are not undertaking any exploration activities at present or would be concurrently with the proposed 3D survey, particularly not in the far offshore environment. Thus, the possible range of the future prospecting, mining, exploration and production activities that could arise will vary significantly in scope, location, extent, and duration depending on whether a resource(s) is discovered, its size, properties and location, etc. As these cannot at this stage be reasonably defined, it is not possible to undertake a reliable assessment of the potential cumulative environmental impacts. It is also possible that the proposed, or future, exploration fails to identify an economic petroleum resource, in which case the potential impacts associated with the production phase would not be realised.

Table 15 summarise the applications for hydrocarbon exploration off the South African West Coast submitted to the Petroleum Agency of South Africa (PASA), and off southern Namibia submitted to the Namibian Ministry of Mines and Energy since 2007, indicating which of these have been successfully taken through to completion. Applications for mineral prospecting rights in the South African Sea Areas (SASA) submitted to the Department of Minerals and Energy are also shown. The purpose of this table, which may not be complete, is to emphasise two things. Firstly, that a large number of applications are submitted annually and secondly, that only a small percentage of those applications submitted (and potentially approved) are taken through to completion. The number of applications submitted and/or approved can therefore not be used as an indication of cumulative impacts.

For example, there have recently been numerous applications by seismic operators for Reconnaissance Permits off the West Coast, particularly in the Deep Water Orange Basin area. Other than this project, there are currently three other applications for 3D surveying being prepared over much the same area of the Deep Water Orange Basin. Should these all be approved, it is, however, highly unlikely that the operators will undertake these surveys either concurrently or sequentially. This again emphasises that the number of applications submitted to PASA cannot be assumed to relate to a realistic assessment of cumulative impacts.

Table 15: Applications for hydrocarbon exploration on the South African West Coast and southern Namibia (grey shading) since 2007, indicating which of these have been undertaken. Applications for mineral prospecting rights are also shown (blue shading).

1072

Furthermore, the assessment methodology used in the EIA by its nature already considers past and current activities and impacts. In particular, when rating the sensitivity of the receptors, the status of the receiving environment (benthic ecosystem threat status, protection level, protected areas, etc.) or threat status of individual species is taken into consideration, which is based to some degree on past and current actions and impacts (e.g. the IUCN conservation rating is determined based on criteria such as population size and rate of decline, area of geographic range / distribution, and degree of population and distribution fragmentation).

The most reliable gauge of cumulative pressures is provided by Sink *et al.* (2019) and Harris *et al.* (2022). The map was generated as part of the NBA 2018 by doing a cumulative pressure assessment in which the impact of both current and historical ocean-based activities on marine biodiversity was determined by spatially evaluating the intensity of each activity and the functional impact to, and recovery time of, the underlying ecosystem types (Figure 50, left). Based on the severity of modification across the marine realm, a map of ecological condition was generated (Figure 50, right). From this it can be determined that the Reconnaissance Permit Area is located in an area experiencing very low cumulative impacts and that the ecological condition is therefore still natural or near-natural.

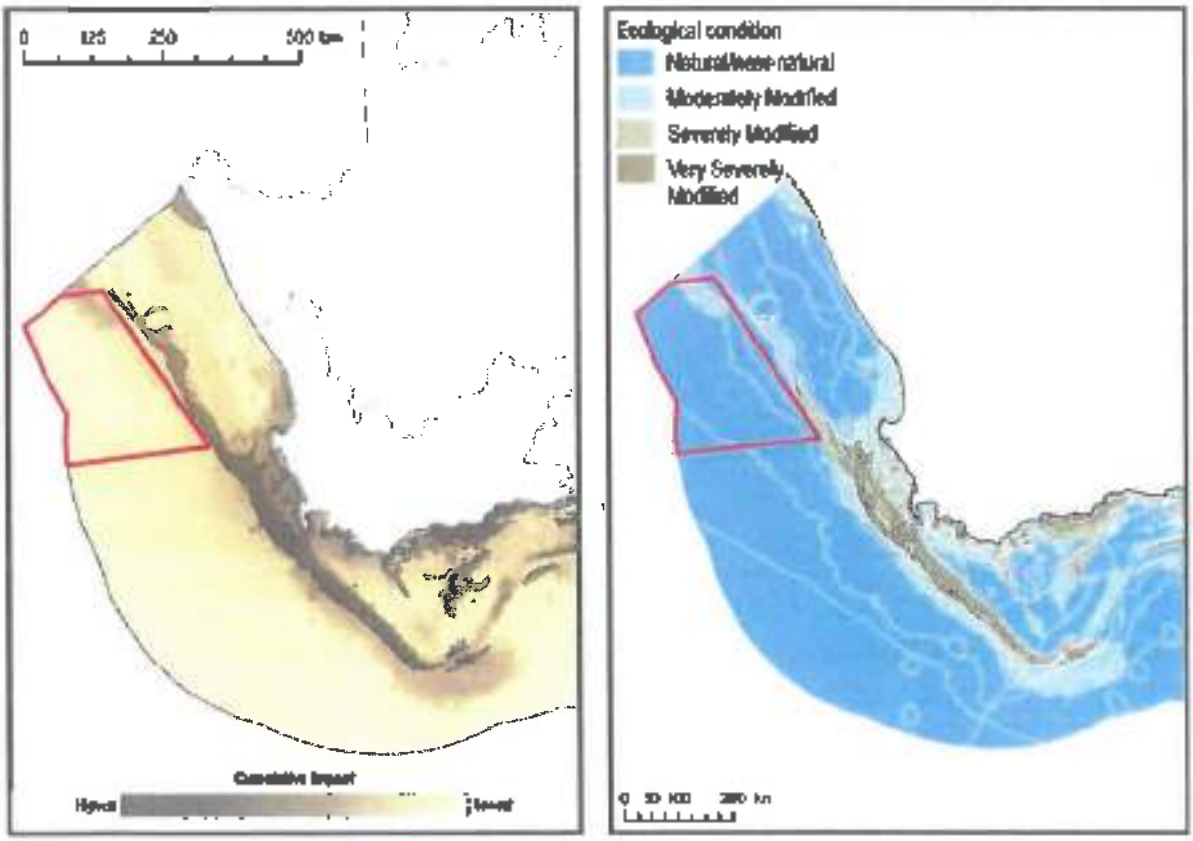

Figure 50: The Reconnaissance Permit Area (red polygon) in relation to cumulative impact on marine biodiversity, based the intensity of all cumulative pressures and the sensitivity of the underlying ecosystem types to each of those pressures (left) and the ecological condition of the marine realm based on the severity of modification as a result of the cumulative impacts (adapted from Sink *et al.* 2019 and Harris *et al.* 2022).

The assessments of impacts of seismic sounds provided in the scientific literature usually consider short-term responses at the level of individual animals only, as our understanding of how such short-term effects relate to adverse residual effects at the population level are limited. Data on behavioural reactions to seismic noise acquired over the short-term could, however, easily be misinterpreted as being less significant than the cumulative effects over the long-term and with multiple exposures, i.e. what is initially interpreted as an impact not having a detrimental effect and thus being of low significance, may turn out to result in a long-term decline in the population, particularly when combined with other acoustic and non-acoustic stressors stressors (e.g. temperature, competition for food, climate change, shipping noise) (Przeslawski *et al.* 2015; Erbe *et al.* 2018, 2019; Booth *et al.* 2020; Derous *et al.* 2020). Physiological stress, for example, may not be easily detectable in marine fauna, but can affect reproduction, immune systems, growth, health, and other important life functions (Rolland *et al.* 2012; Lemos *et al.* 2026). Confounding effects are, however, difficult to separate from those due to seismic surveys.

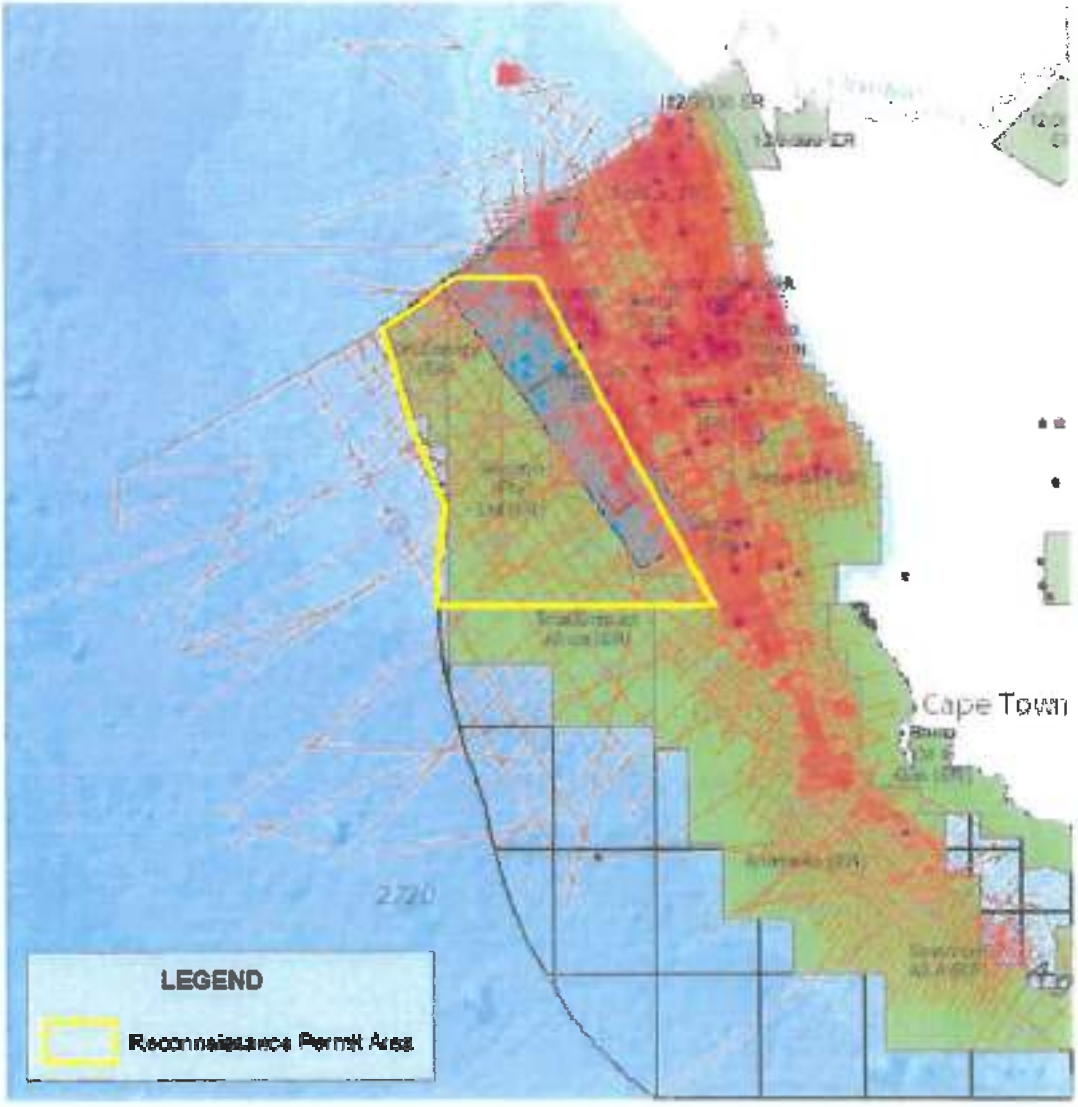

Figure 51: The Reconnaissance Permit Area (yellow polygon) and proposed 3D survey area (white polygon) in relation to historical 2D (red lines) and 3D (blue and purple polygons) surveys conducted on the West Coast between 2001 and 2018 (Source: PASA).

Similarly, potential cumulative impacts on individuals and populations as a result of other seismic surveys undertaken previously, concurrently or subsequently are difficult to assess. A significant adverse residual environmental effect is considered one that affects marine biota by causing a decline in abundance or change in distribution of a population(s) over more than one generation within an area. Natural recruitment may not re-establish the population(s) to its original level within several generations or avoidance of the area becomes permanent. Historic survey data for the West Coast is illustrated in Figure 51, which shows the 2D survey lines shot between 2001 and 2018, and indicates 3D survey areas on the West Coast. Despite the density of seismic survey coverage over the past 17 years, the southern right whale population is reported to be increasing by 6.5% per year (Brandão *et al.* 2017), and the humpback whale by at least 5% per annum (IWC 2012) over a time when seismic surveying frequency has increased, suggesting that, for these population at least, there is no evidence of long-term negative change to population size as a direct result of seismic survey activities. Similar 2D and 3D data for southern Namibia (up to August 2017) are presented in Figure 51.

Reactions to sound by marine fauna depend on a multitude of factors including species, state of maturity, experience, current activity, reproductive state, time of day (Wartzok *et al.* 2004; Southall *et al.* 2007). If a marine animal does react briefly to an underwater sound by changing its behaviour or moving a small distance, the impacts of the change are unlikely to be significant to the individual, let alone the population as a whole (NRC 2005). However, if a sound source displaces a species from an important feeding or breeding area for a prolonged period, impacts at the population level could be significant. The increasing numbers of southern right and humpback whales around the Southern African coast, and their lingering on West Coast feeding grounds long into the summer, suggest that those surveys conducted over the past 17 years have not negatively influenced the distribution patterns of these two migratory species at least. Information on the population trends of resident species of baleen and toothed whales is unfortunately lacking, and the potential effects of seismic surveys on such populations remains unknown.

Consequently, suitable mitigation measures must be implemented during seismic data acquisition to ensure the least possible disturbance of marine fauna in an environment where the cumulative impact of increased background anthropogenic noise levels has been recognised as an ongoing and widespread issue of concern (Koper & Plön 2012; Simmonds *et al.* 2014; Williams *et al.* 2015; Chahouri *et al.* 2021). Should other concurrent seismic exploration activities be undertaken in the Orange Basin, cumulative impacts can be expected.

Despite the difficultly in undertaking a reliable assessment of the potential cumulative environmental impacts of future seismic acquisition in the Deep Water Orange Basin due to likely variation in the scope, extent and duration of proposed surveys, the cumulative impacts of three potential surveys occurring concurrently (see Figure 53) needs to be considered.

The cumulative assessment table below assumes the worst case scenario of three surveys (Searcher, TGS and GX[7]) occurring simultaneously during the summer survey window in 2022/23. The assement methodology adopted by SLR Consulting is used to determine the significance of the cumulative impact.

In the unlikely event that multiple surveys would be undertaken concurrently within the Deep Water Orange Basin Area, associated impacts to marine fauna would be of HIGH intensity and extend

[7] It is understood that IOnI GXT has been declared bankrupt and have ceased operations - as such, the BDM GXT Reconnaissance Permit is considered to be defunct.

REGIONALLY, over the SHORT-term (assuming they take place over the same summer survey window. The impact consequence for cumulative surveys is therefore considered MEDIUM.

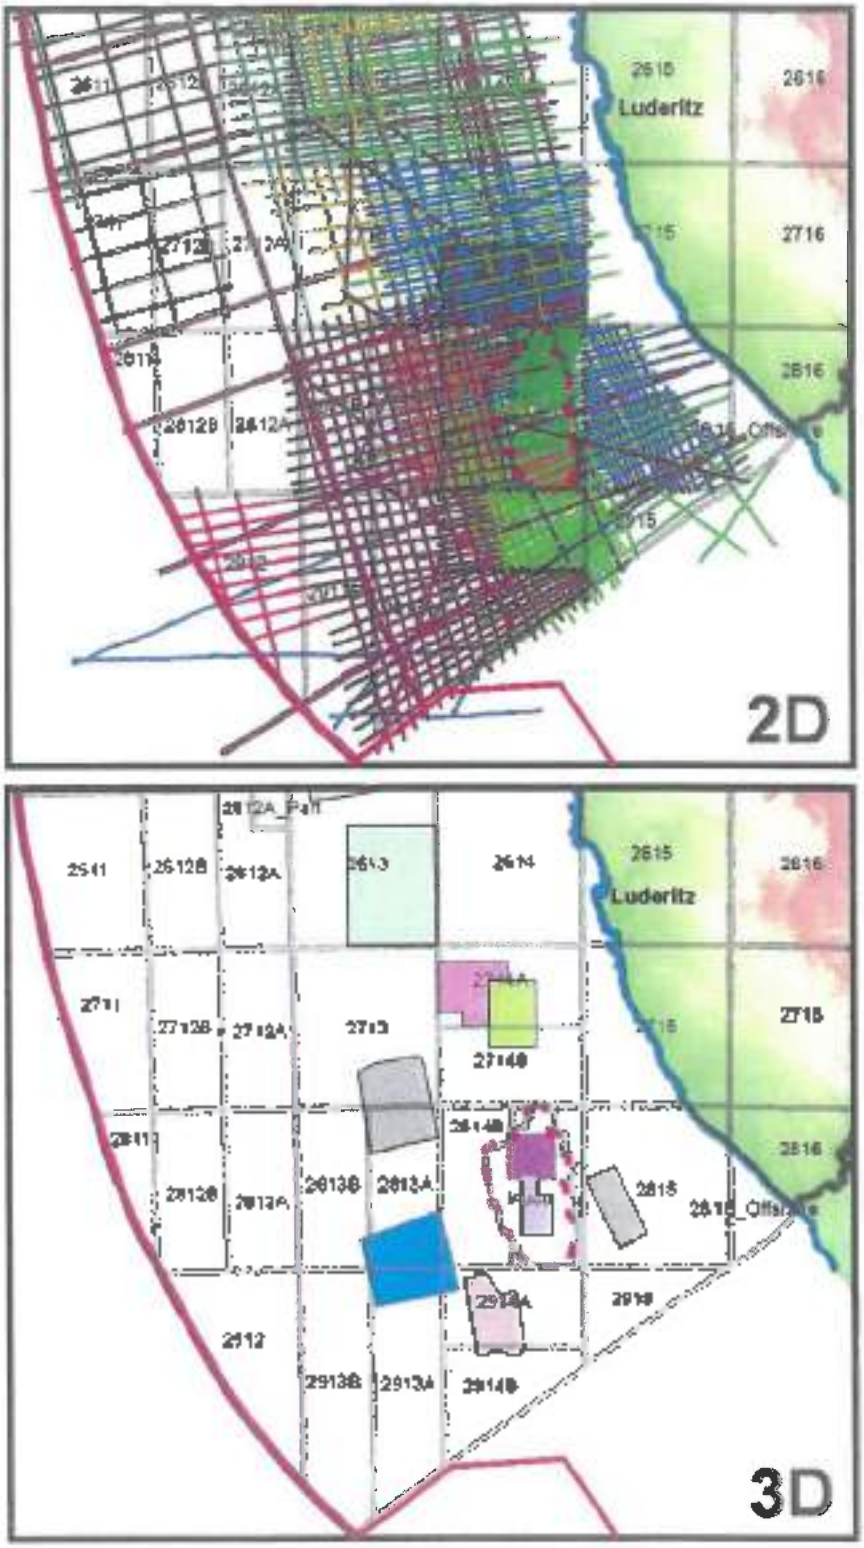

Figure 52: The Reconnaissance Permit Area (red polygon) in relation to historical 2D (top) and 3D (bottom) surveys conducted in southern Namibia up to August 2017 (Source: Namibian MME).

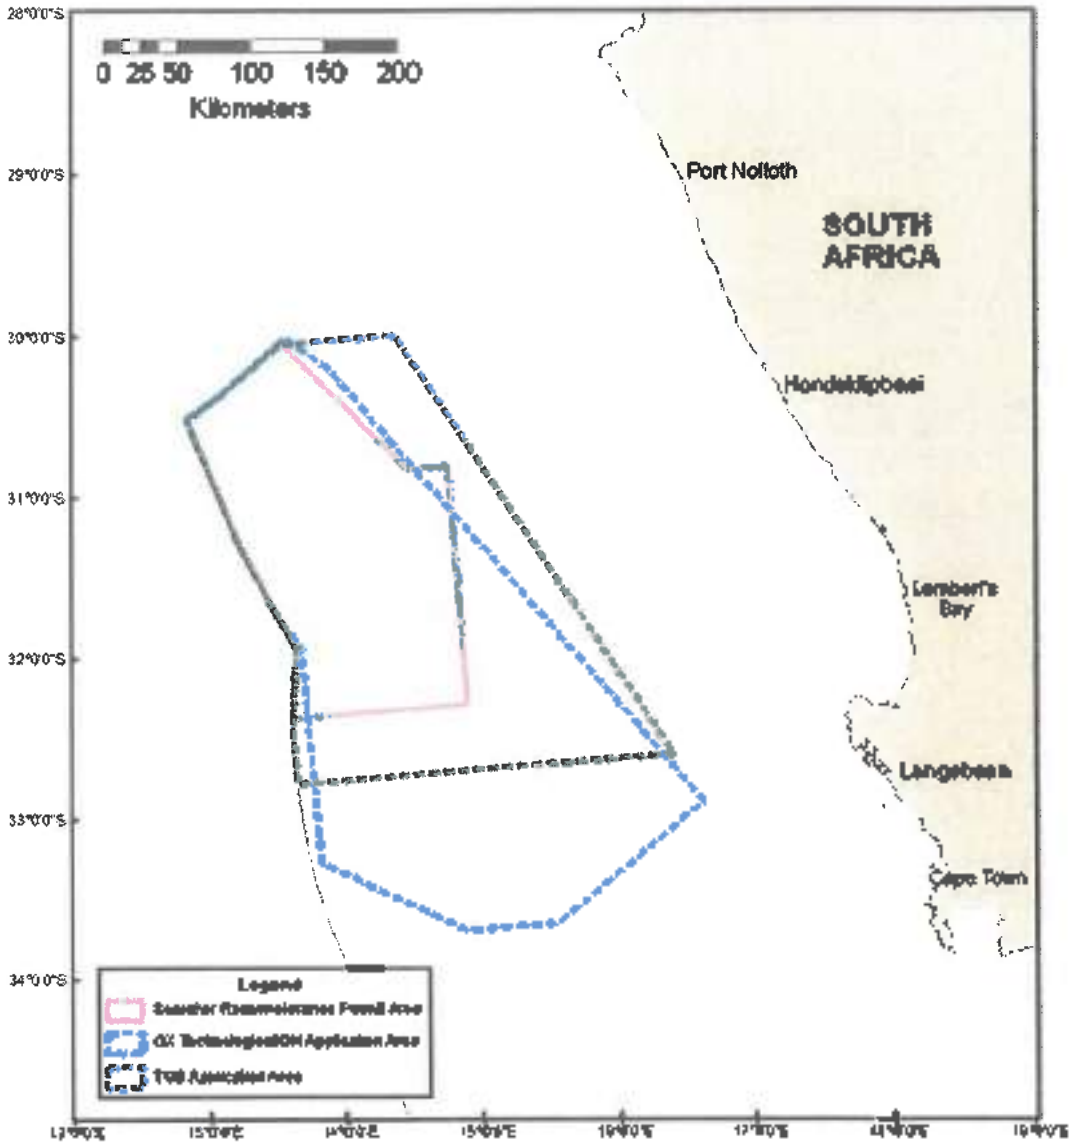

Figure 53: The Reconnaissance Permit Area (shaded) in relation to other pending applications in the Orange Basin Area.

Impact Significance

The impacts to marine fauna associated with concurrent surveys are deemed to be of MEDIUM significance, due to the high sensitivity of the offshore receptors, the very high likelihood of cumulative effects of acoustic impacts on marine fauna.

In applying the EIMS assessment methodology, the numerical approach similarly results in the cumulative impact having a MEDIUM significance.

16	*Impacts to marine fauna of concurrent seismic acquisition by multiple operators*
Project Phase:	**Mobilisation, Operation & Decommissioning**
Type of Impact	**Direct - Cumulative**
Nature of Impact	**Negative**
Sensitivity of Receptor	**High**
Magnitude/Consequence	**MEDIUM**
Intensity	**High**
Extent	**Regional**
Duration	**Short**
Significance	**MEDIUM**
Probability	**Definite**
Confidence	**High**
Reversibility	**Partially Reversible**
Loss of Resources	**Medium**

Identification of Mitigation Measures

The following measures should be considered:

No.	Mitigation measure	Responsibility
1	Should surveys be run simultaneously, ensure that a distance of at least 40 km is maintained between survey vessels[8] until sufficient objective evidence is obtained that a reduced buffer distance is acceptable.	Above on site

Residual Impact Assessment

With the implementation of the above-mentioned controls and mitigation measures, the intensity of the impact would reduce to MEDIUM and the probability of the impact would reduce to LIKELY, but the overall significance would remain MEDIUM.

[8] This 40 km buffer maintained by any other survey vessels aligns to advice by the US Department of Interior (2014) and is considered sufficient on the basis that it provides a corridor between vessels where airgun noise approaches ambient levels such that animals may pass between, and/or the potential cumulative effect beyond this distance is considered to be negligible.

JR28

5. FINDINGS AND RECOMMENDATIONS

5.1 Key Findings

The proposed survey activities to be undertaken by TGS are expected to result in impacts on marine invertebrate fauna in the Orange Basin, ranging from negligible to very low significance. Only in the case of potential impacts to turtles and marine mammals are impacts of low significance expected.

A summary of impacts and mitigation measures of seismic noise on marine fauna is provided in Table 16. Other impacts that may occur during seismic surveys are summarised in Table 17.

Table 16: Summary of the impacts and mitigation of seismic noise.

Impact	Significance (before mitigation)	Significance (after mitigation)
Plankton and ichthyoplankton	Medium	Very Low
Marine invertebrates	Negligible	Negligible
Pelagic fish	Medium	Low
Diving Seabirds	Low	Very Low
Turtles	Medium	Low
Seals	Low	Very Low
Whales and dolphins		
Baleen whale	Medium	Low
Toothed whales and dolphins	Medium	Low

Table 17: Summary of other impacts and mitigation of seismic surveys.

Impact	Significance (before mitigation)	Significance (after mitigation)
Non-seismic noise - vessel	Very Low	Very Low
Vessel lighting	Very Low	Very Low
Hull fouling and ballast water discharge	Very Low	Negligible
Waste Discharges to sea	Very Low	Very Low
Ship strikes and entanglement in gear	Low	Low
Accidental loss of equipment	Very Low	Very Low
Operational spills and vessel collision	Medium	Low

5.2 Environmental Acceptability

If all environmental guidelines, and appropriate mitigation measures recommended in this report are implemented, there is no reason why the proposed seismic survey programme should not proceed. It should also be kept in mind that some of the migratory species are now present year round off the West Coast, and that certain baleen and toothed whales are resident and/or show seasonality opposite to the majority of the baleen whales. Data collected by independent onboard observers should form part of a survey close-out report to be forwarded to the necessary authorities, and any incidence data

8428

and seismic source output data arising from surveys should be made available for analyses of survey impacts in Southern African waters.

5.3 Recommendations

Detailed mitigation measures for seismic surveys in other parts of the world are provided by Weir *et al.* (2006), Weir & Dolman (2007), Compton *et al.* (2007), US Department of Interior (2007), Reyes Reyes *et al.* (2016), Vilardo & Barbosa (2018), Bröker *et al.* (2015) and Bröker (2019). Many of the international guidelines presented in these documents are extremely conservative as they are designed for areas experiencing repeated, high intensity surveys and harbouring particularly sensitive species, or species with high conservation status. A number of countries have more recently updated their guidelines, most of which are based on the JNCC (2010, 2017) recommendations but adapted for specific areas of operation. A review and comparison of these is provided in MaMa CoCo SEA (2015). The guidelines currently applied to seismic surveying in South African waters are those proposed in the Generic EMPR (CCA & CMS 2001) and by Purdon (2018). Purdon (2018) highlights the importance of developing mitigation guidelines both locally and regionally and points out that if South Africa is to maintain environmental integrity, mitigation guidelines for seismic surveys specific to the country, and based on the most recent scientific data, need to be implemented.

These have been updated as necessary to include salient points from recognised international guidelines, particularly the JNCC (2010, 2017) Guidelines and the 2013 New Zealand Code of Conduct for seismic operations (New Zealand Dept. of Conservation 2013). The proposed mitigation is thus comprehensive and in-line with, and in certain instances more comprehensive than, international good-practice industry standards.

Elliott *et al.* (2019) point out that in most cases the mitigation standards adopted are designed to mitigate impacts on marine mammals (e.g. Nowacek *et al.* 2013), with no set of standards or guidelines for sea turtles and fish. Even less in known about the efficacy of mitigation in protecting marine vertebrates from acoustic impacts (Parsons *et al.* 2009). The authors argue that without baseline information on species before surveys (see for example Fossati *et al.* 2018), it is difficult to assess the efficacy of existing guidelines and standards during or after surveys.

Adopting as far as possible the principles outlined in Nowacek & Southall (2016) and Nowacek *et al.* (2013, 2015), the mitigation measures proposed for seismic surveys are as provided below for each phase of a seismic survey operation:

No.	Mitigation measure	Classification
1. Survey Planning		
1.1	Plan seismic surveys to avoid sensitive areas and periods for some marine fauna: • Movement of migratory cetaceans (particularly baleen whales) from their southern feeding grounds into low latitude waters (June/July and late October/November) , and their aggregation on the summer feeding grounds between St Helena Bay and Dassen Island from late October to late December and ensure that migration paths are not blocked by seismic operations. If possible the survey should be undertaken from North to South to avoid these feeding aggregations.	Avoid
1.2	Plan survey, as far as possible, so that the first commencement of airgun firing in a new area (including gun tests) is undertaken during daylight hours.	Abate on site

No.	Mitigation measure	Classification
1.3	Prohibit airgun use (including airgun tests) outside of the Reconnaissance Permit Area.	Avoid
1.4	Although a seismic vessel and its gear may pass through a declared Marine Protected Area, acoustic sources (airguns) must not be operational during this transit.	Avoid
1.5	A 5 km buffer zone where no airgun operation is permitted is recommended around all MPAs	Avoid
2. Key Equipment		
2.1	**Passive Acoustic Monitoring (PAM)**	
2.1.1	Ensure the seismic vessel is fitted with Passive Acoustic Monitoring (PAM) technology, which detects some animals through their vocalisations.	Abate on site
2.1.2	As the survey area would largely be in waters deeper than 1 000 m where sperm whales and other deep-diving odontocetes are likely to be encountered, implement the use of PAM 24-hr a day when the airgun is in operation.	Abate on site
2.1.3	Ensure that the PAM hydrophone streamer is towed in such a way that the interference of vessel noise is minimised.	Abate on site
2.1.4	Ensure the PAM streamer is fitted with at least four hydrophones, of which two are HF and two LF, to allow directional detection of cetaceans.	Abate on site
2.1.5	Ensure spare PAM hydrophone streamers (e.g. 4 heavy tow cables and 6 hydrophone cables) are readily available in the event that PAM breaks down, in order to ensure timeous redeployment.	Abate on site
2.2	Acoustic Source	
2.2.1	Define and enforce the use of the lowest practicable airgun volume for production, and design arrays to maximise downward propagation, minimise horizontal propagation and minimise high frequencies in airgun pulses.	Abate on site
2.2.2	Ensure a display screen for the acoustic source operations is provided to the marine observers. All information relating to the activation of the acoustic source and the power output levels must be readily available to support the observers in real time via the display screen and to ensure that operational capacity is not exceeded.	Abate on site
2.2.3	Ensure the ramp-up noise volumes do not exceed the production volume.	Abate on site
2.2	Streamers	
2.2.1	Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'.	Abate on site
2.2.2	Ensure that solid streamers rather than fluid-filled streamers are used to avoid leaks.	Avoid
3. Key Personnel		
3.1	• Make provision for the placing of a qualified MMOs on board the seismic vessel. As a minimum, one must be on watch during daylight hours for the pre-shoot observations and when the acoustic source is active. • The duties of the MMO would be to: – Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations; – Record airgun activities, including sound levels, "soft-start" procedures and pre-firing regimes; – Observe and record responses of marine fauna to seismic shooting from optimum vantage points, including seabird, large pelagic fish (e.g. shoaling tuna, sunfish, sharks), turtle, seal and cetacean incidence and behaviour	Abate on site

E&25

No:	Mitigation measure:	Classification:
	and any mortality or injuries of marine fauna as a result of the seismic survey. Data captured should include species identification, position (latitude/longitude), distance/bearing from the vessel, swimming speed and direction (if applicable) and any obvious changes in behaviour (e.g. startle responses or changes in surfacing/diving frequencies, breathing patterns) as a result of the seismic activities. Both the identification and the behaviour of the animals must be recorded accurately along with current seismic sound levels. Any attraction of predatory seabirds, large pelagic fish or cetaceans (by mass disorientation or stunning of fish as a result of seismic survey activities) and incidents of feeding behaviour among the hydrophone streamers should also be recorded; – Record sightings of any injured or dead marine mammals, large pelagic fish (e.g. sharks), seabirds and sea turtles, regardless of whether the injury or death was caused by the seismic vessel itself. If the injury or death was caused by a collision with the seismic vessel, the date and location (latitude/longitude) of the strike, and the species identification or a description of the animal should be recorded and included as part of the daily report; – Record meteorological conditions at the beginning and end of the observation period, and whenever the weather conditions change significantly; – Request the delay of start-up or temporary termination of the seismic survey or adjusting of seismic shooting, as appropriate. It is important that MMO decisions on the termination of firing are made confidently and expediently, and following dialogue between the observers on duty at the time. A log of all termination decisions must be kept (for inclusion in both daily and "close-out" reports); – Use a recording spreadsheet (e.g. JNCC, 2017) in order to record all the above observations and decisions; and – Prepare daily reports of all observations, to be forwarded to the necessary authorities as required, in order to ensure compliance with the mitigation measures.	

B20

No.	Mitigation measure	Classification
3.2	• Make provision for placing of a qualified PAM operator on board the seismic vessel. As a minimum, one must be on 'watch' during the pre-shoot observations and when the acoustic source is active. • The duties of the PAM operator would be to: – Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations; – Ensure that the hydrophone cable is optimally placed, deployed and tested for acoustic detections of marine mammals; – Confirm that there is no marine mammal activity within 500 m of the airgun array prior to commencing with the "soft-start" procedures; – Record species identification, position (latitude/longitude), distance and bearing from the vessel and acoustic source, where possible; – Record general environmental conditions; – Record airgun activities, including sound levels, "soft-start" procedures and pre-firing regimes; and – Request the delay of start-up and temporary termination of the seismic survey, as appropriate.	Abate on site
3.3.	Ensure MMOs and PAM operators are briefed on the area-specific sensitivities and on the seismic survey planning (including roles and responsibilities, and lines of communication).	Abate on site
4. Airgun Testing		
4.1	Maintain a pre-shoot watch of 60-minutes before any instances of airgun testing. If only a single lowest power airgun is tested, the pre-shoot watch period can be reduced to 30 minutes.	Avoid / Abate on site
4.2	Implement a "soft-start" procedure if testing multiple airguns. • The "soft-start" should be carried out over a time period proportional to the number of guns being tested and not exceed 20 minutes; airguns should be tested in order of increasing volume; • If testing all airguns at the same time, a 20 minute "soft-start" is required; • If testing a single lowest power airgun a "soft-start" is not required.	Avoid / Abate on site
5. Pre-Start Protocols		
5.1	Implement a dedicated MMO and PAM pre-shoot watch of at least 60 minutes (to accommodate deep-diving species in water depths greater than 200 m).	Avoid / Abate on site
5.2	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if: • during daylight hours it is confirmed: – visually by the MMO during the pre-shoot watch (60 minutes) that there are no penguins or feeding aggregations of diving seabirds, shoaling large pelagic fish, turtles, seals or cetaceans within 500 m of the seismic source, and – by PAM technology that there are no vocalising cetaceans detected in the 500 m mitigation zone. • during times of poor visibility or darkness it is confirmed by PAM technology that no vocalising cetaceans are present in the 500 m mitigation zone during the pre-shoot watch (60 minutes).	Avoid / Abate on site

1083

Ref.	Mitigation measure	Classification
5.3	Delay "soft-starts" if penguins or feeding aggregations of diving seabirds, shoaling large pelagic fish, turtles, seals or cetaceans are observed within the mitigation zone. • A "soft-start" should not begin until 30 minutes after cetaceans depart the 500 m mitigation zone or 30 minutes after they are last seen or acoustically detected by PAM in the mitigation zone. • In the case of penguins, diving seabirds, shoaling large pelagic fish and turtles, delay the "soft-start" until animals are outside the 500 m mitigation zone. • In the case of fur seals, which may occur commonly around the vessel, delay "soft-starts" for at least 10 minutes until it has been confirmed that the mitigation zone is clear of all seal activity. However, if after a period of 10 mins seals are still observed within 500 m of the airgun, the normal "soft-start" procedure should be allowed to commence for at least a 20-minute duration. Seal activity should be carefully monitored during "soft-starts" to determine if they display any obvious negative responses to the airgun and gear or if there are any signs of injury or mortality as a direct result of the seismic activities.	Avoid / Abate on site
5.4	As noted above for planning, when arriving at the survey area for the first time, survey activities should, as far as possible, only commence during daylight hours with good visibility. However, if this is not possible due to prolonged periods of poor visibility (e.g. thick fog) or unforeseen technical issue which results in a night-time start, the initial acoustic source activation (including gun tests) may only be undertaken if the normal 60-minute PAM pre-watch and "soft-start" procedures have been followed.	Avoid / Abate on site
5.5	Schedule "soft-starts" so as to minimise, as far as possible, the interval between reaching full power operation and commencing a survey line. The period between the end of the soft start and commencing with a survey line must not exceed 20 minutes. If it does exceed 20 minutes, refer to breaks in firing below.	Abate on site
6. Line Turns		
6.1	If line changes are expected to take longer than 40 minutes: • Terminate airgun firing at the end of the survey line and implement a pre-shoot search (60 minutes) and "soft-start" procedure (20 minutes) when approaching the next survey line. • If line turn is shorter than 80 minutes (i.e. shorter than a 60-minute pre-shoot watch and 20-minute "soft-start" combined), the pre-shoot watch can commence before the end of the previous survey line.	Abate on site
6.2	If line changes are expected to take less than 40 minutes, airgun firing can continue during the line change if: • The power is reduced to 180 cubic inches (or as close as is practically feasible) at standard pressure. Airgun volumes of less than 180 cubic inches can continue to fire at their operational volume and pressure. • The Shot Point Interval (SPI) is increased to provide a longer duration between shots, with the SPI not to exceed 5 minutes; and • The power is increased and the SPI is decreased in uniform stages during the final 10 minutes of the line change (or geophone repositioning), prior to data collection re-commencing (i.e. a form of mini soft start). • Normal MMO and PAM observations continue during this period when reduced power airgun is firing.	Abate on site

No.	Mitigation measure	Classification
7. Shut-Downs		
7.1	Terminate seismic shooting on: • observation and/or detection of penguins or feeding aggregations of diving seabirds, turtles, slow swimming large pelagic fish (including whale sharks, basking sharks, manta rays) or cetaceans within the 500 m mitigation zone. • observation of any obvious mortality or injuries to cetaceans, turtles, seals or mass mortalities of squid and fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO to be as a direct result of the survey.	Abate on site
7.2	Depending the species, specific mitigation will be implemented to continue the survey operations, as specified below: • For specific species such as turtles, penguins, diving seabirds and slow swimming large pelagic fish (including whale sharks, basking sharks, manta rays), terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic 'pause', no soft-start required). • For cetaceans, terminate shooting until such time as there has been a 30 minute delay from the time the animal was last sighted within the mitigation zone before the commencement of the normal soft start procedure.	Abate on site
8. Breaks in Airgun Firing		
8.1	If after breaks in firing, the airgun can be restarted within 5 minutes, no soft-start is required and firing can recommence at the same power level provided no marine mammals have been observed or detected in the mitigation zone during the break-down period.	Abate on site
8.2	For all breaks in firing of longer than 5 minutes, but less than 20 minutes, implement a "soft-start" of similar duration, assuming there is continuous observation by the MMO and PAM operator during the break.	Abate on site
8.3	For all breaks in firing of 20 minutes or longer, implement a 60-minute pre-shoot watch and 20-minute "soft-start" procedure prior to the survey operation continuing.	Abate on site
8.4	For planned breaks, ensure that there is good communication between the seismic contractor and MMOs and PAM operators in order for all parties to be aware of these breaks and that early commencement of pre-watch periods can be implemented to limit delays.	Abate on site
9. PAM Malfunctions		
9.1	If the PAM system malfunctions or becomes damaged during night-time operations or periods of low visibility, continue operations for 30 minutes without PAM if no marine mammals were detected by PAM in the mitigation zones in the previous 2 hours, while the PAM operator diagnoses the issue. If after 30 minutes the diagnosis indicates that the PAM gear must be repaired to solve the problem, reduce power to 160 cubic inches. Firing of the reduced power gun may continue for 30 minutes while PAM is being repaired, the last 10-minute of which is a 10-minute ramp up to full power (mini "soft-start"). If the PAM repair will take longer than 60 minutes, stop surveying until such time as a functional PAM system can be redeployed and tested.	Abate on site

No.	Mitigation measure	Classification
9.2	If the PAM system breaks down during daylight hours, continue operations for 20 minutes without PAM, while the PAM operator diagnoses the issue. If the diagnosis indicates that the PAM gear must be repaired to solve the problem, operations may continue for an additional 2 hours without PAM monitoring as long as: • No marine mammals were detected by PAM in the mitigation zones in the previous 2 hours; • Two MMOs maintain watch at all times during operations when PAM is not operational; • The time and location in which operations began and stop without an active PAM system is recorded.	Abate on site

Vessel and Aircraft Operations

No.	Mitigation measure	Classification
1	Pre-plan flight paths to ensure that no flying occurs over seabird and seal colonies and offshore islands by at least 1 852 m (i.e. 1 nm)	Avoid / abate on site
2	Avoid extensive low-altitude coastal flights by ensuring that the flight path is perpendicular to the coast, as far as possible	Avoid/ abate on site
3	Brief all pilots on the ecological risks associated with flying at a low level along the coast or above marine mammals	Avoid
4	The lighting on the survey and support vessels should be reduced to a minimum compatible with safe operations whenever and wherever possible. Light sources should, if possible and consistent with safe working practices, be positioned in places where emissions to the surrounding environment can be minimised	Reduce at Source
5	Keep disorientated, but otherwise unharmed, seabirds in dark containers for subsequent release during daylight hours. Ringed/banded birds should be reported to the appropriate ringing/banding scheme (details are provided on the ring)	Repair or Restore
6	Avoid the unnecessary discharge of ballast water.	Reduce at source
7	Use filtration procedures during loading in order to avoid the uptake of potentially harmful aquatic organisms, pathogens and sediment that may contain such organisms	Avoid/reduce at source
8	Ensure that routine cleaning of ballast tanks to remove sediments is carried out, where practicable, in mid-ocean or under controlled arrangements in port or dry dock, in accordance with the provisions of the ship's Ballast Water Management Plan	Avoid/reduce at source
9	Ensure all equipment (e.g. arrays, streamers, tail buoys etc) that has been used in other regions is thoroughly cleaned prior to deployment	Avoid/Reduce at Source
10	Implement a waste management system that addresses all wastes generated at the various sites, shore-based and marine. This should include: – Separation of wastes at source; – Recycling and re-use of wastes where possible; – Treatment of wastes at source (maceration of food wastes, compaction, incineration, treatment of sewage and oily water separation).	Avoid/Reduce at Source
11	Implement leak detection and repair programmes for valves, flanges, fittings, seals, etc.	Avoid/Reduce at Source

JL28

No.	Mitigation measure	Classification
12	Use a low-toxicity biodegradable detergent for the cleaning of all deck spillages.	Reduce at Source
13	The vessel operators should keep a constant watch for marine mammals and turtles in the path of the vessel.	Avoid
14	Keep watch for marine mammals behind the vessel when tension is lost on the towed equipment and either retrieve or regain tension on towed gear as rapidly as possible.	Avoid
15	Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'.	Avoid
16	Ensure vessel transit speed between the survey area and port is a maximum of 12 knots (22 km/hr), except in the MPAs where it is reduced further to 10 knots (18 km/hr) as well as when they are present in the vicinity.	Avoid/reduce at source
17	Ensuring that loads are lifted using the correct lifting procedure and within the maximum lifting capacity of crane system.	Avoid
18	Minimise the lifting path between vessels	Avoid
19	Undertake frequent checks to ensure items and equipment are stored and secured safely on board each vessel.	Avoid
20	In the event that equipment is lost during the operational stage, assess safety and metocean conditions before performing any retrieval operations. Establishing a hazards database listing the type of gear left on the seabed and/or in the Reconnaissance Permit Area with the dates of abandonment/loss and locations, and where applicable, the dates of retrieval	Repair/restore
21	Use low toxicity dispersants cautiously and only with the permission of DFFE.	Abate on and off site
22	As far as possible, and whenever the sea state permits, attempt to control and contain the spill at sea with suitable recovery techniques to reduce the spatial and temporal impact of the spill	Abate on site
23	Ensure adequate resources are provided to collect and transport oiled birds to a cleaning station.	Restore
24	Ensure offshore bunkering is not undertake in the following circumstances: – Wind force and sea state conditions of ≥6 on the Beaufort Wind Scale; – During any workboat or mobilisation boat operations; – During helicopter operations; – During the transfer of in-sea equipment; and – At night or times of low visibility.	Avoid / Reduce at source

It is further recommended that seismic operators and holders of hydrocarbon exploration licences give consideration to contributing to a centrally managed research fund. Collaboration across the industry to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study to quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in southern African waters.

APPENDIX 1: METHOD FOR ASSESSING IMPACT SIGNIFICANCE

The following convention was used to determine significance ratings in the assessment. For further details the reader is referred to Chapter 3 and Appendix 8 of the EA Amendment Report.

The impact significance rating methodology, as provided by EIMS, is guided by the requirements of the NEMA EIA Regulations, 2014. The broad approach to the significance rating methodology is to determine the environmental risk (ER) by considering the consequence (C) of each impact (comprising Nature, Extent, Duration, Magnitude, and Reversibility) and relate this to the probability/ likelihood (P) of the impact occurring. This determines the environmental risk. In addition other factors, including cumulative impacts, public concern, and potential for irreplaceable loss of resources, are used to determine a prioritisation factor (PF) which is applied to the ER to determine the overall significance (S).

The significance (S) of an impact is determined by applying a prioritisation factor (PF) to the environmental risk (ER). The environmental risk is dependent on the consequence (C) of the particular impact and the probability (P) of the impact occurring. Consequence is determined through the consideration of the Nature (N), Extent (E), Duration (D), Magnitude (M), and reversibility (R) applicable to the specific impact.

For the purpose of this methodology the consequence of the impact is represented by:

$$C = \frac{(E + D + M + R) * N}{4}$$

Each individual aspect in the determination of the consequence is represented by a rating scale as defined in Table.

Table1: Criteria for determination of impact consequence

Aspect	Score	Definition
Nature	-1	Likely to result in a negative/ detrimental impact
	+1	Likely to result in a positive/ beneficial impact
Extent	1	Activity (i.e. limited to the area applicable to the specific activity)
	2	Site (i.e. within the development property boundary),
	3	Local (i.e. the area within 5 km of the site),
	4	Regional (i.e. extends between 5 and 50 km from the site
	5	Provincial / National (i.e. extends beyond 50 km from the site)
Duration	1	Immediate (<1 year)
	2	Short term (1-5 years),
	3	Medium term (6-15 years),
	4	Long term (the impact will cease after the operational life span of the project),
	5	Permanent (no mitigation measure of natural process will reduce the impact after construction).

Aspect	Score	Definition
Magnitude/ Intensity	1	Minor (where the impact affects the environment in such a way that natural, cultural and social functions and processes are not affected),
	2	Low (where the impact affects the environment in such a way that natural, cultural and social functions and processes are slightly affected),
	3	Moderate (where the affected environment is altered but natural, cultural and social functions and processes continue albeit in a modified way),
	4	High (where natural, cultural or social functions or processes are altered to the extent that it will temporarily cease), or
	5	Very high / don't know (where natural, cultural or social functions or processes are altered to the extent that it will permanently cease).
Reversibility	1	Impact is reversible without any time and cost.
	2	Impact is reversible without incurring significant time and cost.
	3	Impact is reversible only by incurring significant time and cost.
	4	Impact is reversible only by incurring prohibitively high time and cost.
	5	Irreversible impact

Once the C has been determined the ER is determined in accordance with the standard risk assessment relationship by multiplying the C and the P. Probability is rated/scored as per Table.

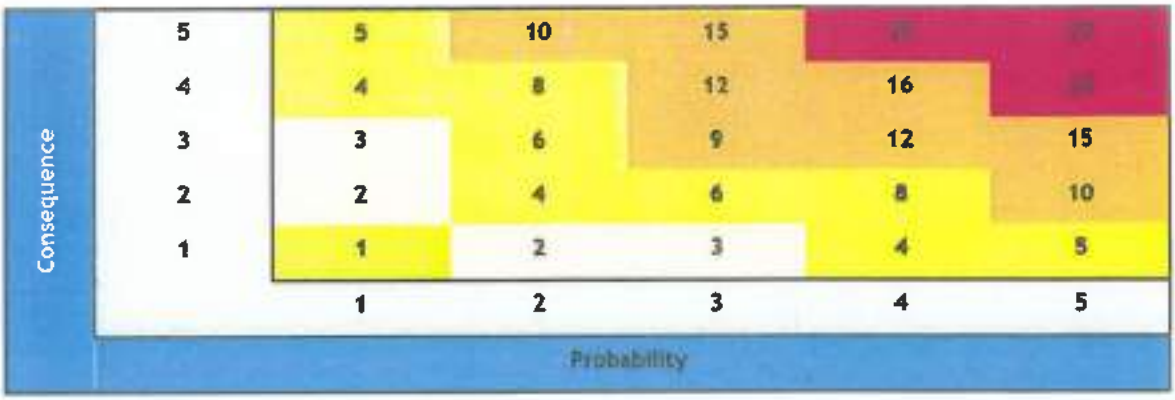
Table 2: Probability scoring

Probability	1	Unlikely/Improbable (the possibility of the impact materialising is very low as a result of design, historic experience, or implementation of adequate corrective actions; <25%),
	2	Possible/Low probability (there is a possibility that the impact will occur; >25% and <50%),
	3	Likely/Medium probability (the impact may occur; >50% and <75%),
	4	Highly Likely/High probability (it is most likely that the impact will occur - > 75% probability), or
	5	Definite (the impact will occur),

The result is a qualitative representation of relative ER associated with the impact. ER is therefore calculated as follows:

$$ER = C \times P$$

Table 3: Determination of environmental risk



The outcome of the environmental risk assessment will result in a range of scores, ranging from 1 through to 25. These ER scores are then grouped into respective classes as described in Table .

Table 4: Significance classes

Risk Score	Description
1	Negligible (i.e. where impact has an insignificant environmental risk)
>1; 3	Very Low (i.e. where the impact has a very low environmental risk)
>3; < 9	Low (i.e. where the impact is unlikely to be a significant environmental risk).
≥ 9; < 17	Medium (i.e. where the impact could have a significant environmental risk).
≥ 17	High (i.e. where the impact will have a significant environmental risk).

The impact ER will be determined for each impact without relevant management and mitigation measures (pre-mitigation), as well as post implementation of relevant management and mitigation measures (post-mitigation). This allows for a prediction in the degree to which the impact can be managed/ mitigated.

Further to the assessment criteria presented above it is necessary to assess each potentially significant impact in terms of:

- Cumulative impacts; and
- The degree to which the impact may cause irreplaceable loss of resources.

To ensure that these factors are considered, an impact prioritisation factor (PF) will be applied to each impact ER (post-mitigation). This prioritisation factor does not aim to detract from the risk ratings but rather to focus the attention of the decision-making authority on the higher priority / significance issues and impacts. The PF will be applied to the ER score based on the assumption that relevant suggested management/ mitigation impacts are implemented.

Table 5: Criteria for the determination of prioritisation

Cumulative Impact (CI)	Low (1)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is unlikely that the impact will result in spatial and temporal cumulative change.
	Medium (2)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is probable that the impact will result in spatial and temporal cumulative change.
	High (3)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/definite that the impact will result in spatial and temporal cumulative change.
Irreplaceable loss of resources (LR)	Low (1)	Where the impact is unlikely to result in irreplaceable loss of resources.
	Medium (2)	Where the impact may result in the irreplaceable loss (cannot be replaced or substituted) of resources but the value (services and/or functions) of these resources is limited.
	High (3)	Where the impact may result in the irreplaceable loss of resources of high value (services and/or functions).

The value for the final impact priority is represented as a single consolidated priority, determined as the sum of each individual criteria represented in Table. The impact priority is therefore determined as follows:

$$\text{Priority} = CI + LR$$

The result is a priority score which ranges from 3 to 9 and a consequent PF ranging from 1 to 1.5 (refer to Table).

Table 6: Determination of prioritisation factor

Priority	Ranking	Prioritisation Factor
2	Low	1
3	Medium	1.125
4	Medium	1.25
5	Medium	1.375
6	High	1.5

In order to determine the final impact significance the PF is multiplied by the ER of the post mitigation scoring. The ultimate aim of the PF is to be able to increase the post mitigation environmental risk rating by a factor of 0.5, if all the priority attributes are high (i.e. if an impact comes out with a medium environmental risk after the conventional impact rating, but there is significant cumulative impact potential and significant potential for irreplaceable loss of resources, then the net result would be to upscale the impact to a high significance).

5203

Table 7: Environmental Significance Rating

Value	Description
0	No impact
-1	Impact occurs but is negligible
> -1 ≤ 3	Very Low negative
< -10	Low negative (i.e. where this impact would not have a direct influence on the decision to develop in the area).
≥ -10 < -20	Medium negative (i.e. where the impact could influence the decision to develop in the area).
< -20	High negative (i.e. where the impact would influence on the decision to develop in the area).

Academic Qualifications

- BSc (Zoology and Botany), University of Natal, Pietermaritzburg, 1982
- BSc (Hons) (Zoology), University of Cape Town, 1983
- MSc (Zoology), University of Cape Town, 1987
- PhD, Department of Fisheries Biology of the Institute for Marine Science at the Christian-Albrechts University, Kiel, Germany, 1995

Membership in Professional Societies

- South African Council for Natural Scientific Professions (Pr.Sci.Nat. No: 400327/06)
- South African Institute of Ecologists and Environmental Scientists
- International Association of Impact Assessment (South Africa)

Employment History and Professional Experience

1998-present: Director: Pisces Environmental Services (Pty) Ltd. Specifically responsible for environmental impact assessments, baseline and monitoring studies, marine specialist studies, and environmental management plan reports.

1998: Senior researcher on contract to Namdeb Diamond Corporation and De Beers Marine South Africa, at the University of Cape Town; investigating and monitoring the impact of diamond mining on the marine environment and fisheries resources; experimental design and implementation of dive surveys; collaboration with fishermen and diamond divers; deep water benthic sampling, sample analysis and macrobenthos identification.

1996-1998: Senior researcher at the University of Cape Town, on contract to the Chief Director: Marine and Coastal Management (South African Department of Environment Affairs and Tourism); investigating and monitoring the experimental fishery for perlemoen on the Cape south coast; experimental design and implementation of dive surveys for stock assessments; collaboration with fishermen, supervision of Honours and Masters students.

1989-1994: Institute for Marine Science at the Christian-Albrechts University of Kiel, Germany; research assistant in a 5 year project to investigate the population dynamics of mussels and cockles in the Schleswig-Holstein Wadden Sea National Park (employment for Doctoral degree); extensive and intensive dredge sampling for stock assessments, collaboration with and mediation between, commercial fishermen and National Park authorities, co-operative interaction with colleagues working in the Dutch and Danish Wadden Sea.

supervision of Honours and Masters projects and student assistants, diving and underwater scientific photography. Scope of doctoral study: experimental design and implementation of a regular sampling program including: (i) plankton sampling and identification of lamellibranch larvae, (ii) reproductive biology and condition indices of mussel populations, (iii) collection of mussel spat on artificial collectors and natural substrates, (iv) sampling of recruits to the established populations, (v) determination of small-scale recruitment patterns, and (vi) data analysis and modelling. Courses and practicals attended as partial fulfilment of the degree: Aquaculture, Stock Assessment and Fisheries Biology, Marine Chemistry, and Physical and Regional Oceanography.

1988-1989: Australian Institute of Marine Science; volunteer research assistant and diver; implementation and maintenance of field experiments, underwater scientific photography, digitizing and analysis of stereo-photoquadrats, larval culture, analysis of gut contents of fishes and invertebrates, carbon analysis

1985-1987: Sea Fisheries Research Institute of the South African Department of Environment Affairs and Tourism: scientific diver on deep diving surveys off Cape Agulhas: censusing fish populations, collection of benthic species for reef characterization.

South African National Research Institute of Oceanography and Port Elizabeth Museum: technical assistant and research diver; quantitative sampling of benthos in Mossel Bay, and census of fish populations in the Tsitsikamma National Park.

University of Cape Town, Department of Zoology and Percy Fitzpatrick Institute of African Ornithology: research assistant; supervisor of diving survey and collection of marine invertebrates, Prince Edward Islands.

1984-1984: University of Cape Town, Department of Zoology: research assistant (employment for M\Sc Degree) and demonstrator of first year Biological Science courses. Scope of MSc study: the biology, ecology and fishery of the western Cape linefish species *Pachymetopon blochii*, including (i) socio-economic survey of the fishery and relevant fishing communities, (ii) collection and analysis of data on stomach contents, reproductive biology, age and growth, (iii) analysis of size-frequency and catch statistics, (iv) underwater census, (v) determination of hook size selectivity, (vi) review of historical literature and (vii) recommendations to the Sea Fisheries Research Institute of the South African Department of Environment Affairs and Tourism for the modification of existing management policies for the hottentot fishery.

DECLARATION OF THE ENVIRONMENTAL SPECIALIST

I, ...Dr Andrea Pulrich... (Full Name and Surname) declare that –

General declaration:

- I act as an independent specialist in this application.
- I will perform the work relating to the application in an objective manner, even if this results in views and findings that are not favorable to the applicant.
- I declare that there are no circumstances that may compromise my objectivity in performing such work.
- I have expertise in conducting undertaking the specialist work as required, including knowledge of the Act, Regulations and any guidelines that have relevance to the proposed activity.
- I will comply with the Act, Regulations, and all other applicable legislation.
- I have not, and will not engage in, conflicting interest in the undertaking of the activity.
- I understand to disclose to the applicant and competent authority all material information in my possession that reasonably has or may have the potential of influencing- any decision to be taken with respect to the application by the competent authority; and the objectivity of any report, plan or document to be prepared by myself for submission to the competent authority.
- I have taken into account, to the extent possible, the matters referred to in Regulation 18 when preparing the report, plan or document.
- I will provide the competent authority with access to all information at my disposal regarding the application, whether such information is favourable to the applicant or not
- All the particulars furnished by me this form are true and correct.
- I will perform all other obligations as expected from an environmental assessment practitioner in terms of the Regulations.
- I am aware of what constitutes an offence in terms of Regulation 48 and that a person convicted of an offence in terms of Regulation 48(1) is liable to the penalties as contemplated in Section 49B of the Act.

Disclosure of Vested Interest

I do not have and will not have any vested interest (either business, financial, personal or other) in the proposed activity proceeding other than remunerative for work performed in terms of the Regulations.

Signature of the Specialist: Andrea Pulrich

Name of Company: Pisces Environmental Services (Pty) Ltd

Date: 2 December 2022

UNDERTAKING UNDER OATH/AFFIRMATION

I, ...Andrea Pulfrich...swear under oath/affirm that all the information submitted or to be submitted for the purposes of this application is true and correct.

CAPRICORN MARINE ENVIRONMENTAL PTY LTD

PROPOSED 3D SEISMIC SURVEY WITHIN THE ORANGE BASIN

WEST COAST, SOUTH AFRICA

Fisheries Specialist Study

---

20 September 2022

EXPERTISE AND DECLARATION OF INDEPENDENCE

This report was prepared by David Japp and Sarah Wilkinson of Capricorn Marine Environmental (Pty) Ltd. Dave Japp has a BSc degree in Zoology from the University of Cape Town (UCT) and a MSc degree in Fisheries Science from Rhodes University. Sarah Wilkinson has a BSc (Hons) degree in Botany from UCT. Both have considerable experience in undertaking specialist environmental impact assessments relating to South African commercial fisheries and fish stocks. David Japp has worked in the field of fisheries science and resource assessment since 1987. His work has included environmental economic assessments and the evaluation of environmental impacts on commercial fisheries. Sarah Wilkinson has worked on marine resource assessments, specialising in spatial and temporal analysis (GIS) of fisheries.

This specialist report was compiled for EIMS on behalf of TGS Geophysical Company (UK) Ltd, for their use during an Environmental Management Plan (EMP) Process associated with a Reconnaissance Permit Application for an area situated within the Orange Basin off the West Coast of South Africa. This specialist study will form an integral component of the EMP and will help to ensure that the approach meets the current environmental management best practice in terms of sustainable development. We do hereby declare that Capricorn Marine Environmental (Pty) Ltd is financially and otherwise independent of EIMS and the Applicant.

Dave Japp

Sarah Wilkinson

EXECUTIVE SUMMARY

TGS Geophysical Company (UK) Limited ("TGS") is applying for a Reconnaissance Permit to undertake prospective three-dimensional (3D) seismic survey acquisition off the West Coast of South Africa in order to investigate for oil and gas reserves. The reconnaissance application area of 57 400 km^2 is situated 120 km from the coastline at its closest approach and covers a water depth range of approximately 500 m to 4000 m. TGS is applying for authorisation to survey the full block area, although the acquisition area would likely be planned across a smaller area within the Reconnaissance Permit area. The survey would be undertaken by a dedicated vessel towing a short array of airguns (sound source) and a long array of up to 10 streamer cables (passive receivers). The streamer array would be towed at a depth of approximately 8 m below the sea surface and would extend up to 12 km or 8 km astern of vessel, respectively. It is anticipated that the total survey duration would be approximately 70 days.

Environmental Impact Management Services Pty Ltd (EIMS) has been appointed as the Independent Environmental Practitioner (EAP) to undertake an Environmental Management Plan (EMP) process for the proposed exploration activities. Capricorn Marine Environmental (Pty) Ltd has been contracted to provide a specialist assessment of the impact of the proposed activities on the fishing industry. Several aspects of the proposed activities were identified as posing a potential risk to the fishing industry and these risks were assessed with respect to each commercial fishing sector operational off the West Coast of South Africa. The aspects of the planned operations that were identified as posing a risk to fisheries include 1) noise emitted by the seismic survey operation; 2) safety zone around the survey vessel; and 3) accidental events such as hydrocarbon spill and loss of survey equipment to sea. The potential impacts arising from these aspects were assessed under the following categories: 1) the effects of increased ambient sound on fish behaviour and associated effects on recruitment and catch rates; 2) temporary exclusion of vessels from accessing fishing grounds; 3) water contamination due to accidental release of marine diesel and 4) obstruction to fishing operations as a result of lost equipment.

The impact of temporary exclusion from fishing ground was assessed on each fishing sector based on the type of gear used and the proximity of fishing areas in relation to the proposed survey area (inclusive of vessel manoeuvring areas beyond the boundary of the seismic acquisition area). The impact on catch rates due to sound elevation levels was assessed using the results of a Sound Transmissions Modelling Loss (STML) report and sensitivity / vulnerability differences amongst the targeted fish species identified for each sector. The impact significance was assessed based on a combination of the magnitude, duration and extent as well as the probability of it occurring. Significance was assigned to the pre-mitigation impact (i.e. before additional mitigation measures are applied, but taking into account embedded controls specified as part of the project description) and residual impacts after additional mitigation is applied. The table below provides a summary of the impacts on fisheries of each of the identified project activities, where the impact significance range across fishing sectors is presented before and after the implementation of recommended mitigation measures.

Sound generated during the seismic surveys is expected to be in the order of 255-256 dB re 1 µPa at 1 m (Peak sound pressure level) at an operating frequency range of 5 – 300 Hz. The zone of potential injury for fish eggs and larvae, as well as fish species with a swim bladder, is predicted to be within 160 m from the array source. Fish species without swim bladders have higher injury impact thresholds, and therefore a smaller zone of potential injury within 80 m from the array source. Impact of mortal injury to fish eggs and larvae and fish with a swim bladder as a result of cumulative exposure to multiple airgun array pulses was assessed to be 50 m from the adjacent survey lines for a 24-hour survey operation. The zones of potential recoverable injury (TTS effect) for fish species with and without swim bladders are predicted to be up to 3.5 km from the survey lines for the 24-hour operation scenarios considered. Existing experimental data regarding recoverable injury and TTS impacts for fish eggs and larvae is sparse and no guideline recommendations have been provided.

However, based on a subjective approach, noise impacts related to recoverable injury and TTS on fish eggs and larvae are expected to be moderate in the near field (tens of meters). Impact is expected to be low at intermediate field (hundreds of meters) and far field (thousands of meters) from the source location. Generation of noise during the seismic survey has the potential to affect catch due to behavioural responses of fish to increased noise levels. For the current project, the potential impact of elevated sound levels (produced by seismic airguns) on behavioural disturbance to fish (and associated effects on commercial catch rates) may extend to a distance of ~4 km from the sound source. With the implementation of the project controls and mitigation measures, the residual impact due to seismic noise is considered to be of LOW NEGATIVE significance for the large pelagic longline and tuna pole-line sectors. Due to the remote location of the Reconnaissance Permit area, noise would be expected to attenuate to below threshold levels before reaching fishing grounds of all other sectors viz. the demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, traditional linefish, west coast rock lobster and small-scale fisheries sectors. The Reconnaissance Permit area does not coincide with spawning areas of key commercial species and noise generated by the seismic source would be expected to attenuate to below threshold levels for behavioural disturbance before reaching inshore recruitment and/or nursery areas. The Reconnaissance Permit area is situated well offshore of distributional area of snoek during its spawning and migration periods (an important species for the linefish and small-scale fisheries sectors).

During the seismic survey, fishing vessels would be required to maintain a safe operational distance from the vessel which may extend up to 6 nautical miles. The impact of potential exclusion was assessed for each commercial sector based on the affected area of fishing ground and the amount of catch reported within the Reconnaissance Permit area. The impact of potential exclusion resulting from the proposed seismic survey is the same as for the noise described above. With the implementation of the project controls and mitigation measures, the residual impact due to fisheries exclusion is considered to be of LOW NEGATIVE significance for large pelagic longline and tuna pole-line sectors. There is no impact expected on the demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, traditional linefish, west coast rock lobster and small-scale fisheries sectors.

It is recommended that the survey avoid taking place during June and July during the peak period of fishing activity for the large pelagic longline sector within the area. Prior to the commencement of survey activities, affected parties should be informed of the navigational co-ordinates of the proposed survey acquisition area, timing and duration of proposed activities and any implications relating to the exclusion zone that would be requested, as well as the movements of support vessels related to the project. The relevant fishing associations include FishSA, incorporating the main commercial fishery sectors, as well as the SA Tuna Association, SA Tuna Longline Association, Fresh Tuna Exporters Association and small-scale fishery groups including the South African United Fishers Front (SAUFF). Other key stakeholders should be notified prior to commencement and on completion of the project. These include; the South African Navy Hydrographic Office (SANHO), South African Maritime Safety Association (SAMSA), Ports Authority and DFFE Vessel Monitoring, Control and Surveillance Unit in Cape Town (Vessel Monitoring System Unit).

For the duration of the survey, a navigational warning should be broadcast to all vessels via Navigational Telex (Navtex) and Cape Town radio. In addition, it is recommended that updates of the scheduled weekly survey plan should be circulated to the operators of affected fishing vessels on a daily basis. A Fisheries Liaison Officer (FLO) should be present on board the survey vessel or escort vessel for the duration of the survey in order to facilitate communications between the survey and fishing vessels in the Reconnaissance Permit area.

1 INTRODUCTION

1.1 BACKGROUND

TGS Geophysical Company (UK) Limited ("TGS") is applying for a Reconnaissance Permit to undertake a speculative three-dimensional (3D) seismic survey to investigate for offshore oil and gas reserves within the Orange Basin, off the West Coast of South Africa. Although the Reconnaissance Permit application area extends over a number of licence blocks between the South African – Namibian border and Cape Columbine, the proposed 3D acquisition area is confined to the Deep Water Orange Basin Block. The Reconnaissance Permit application area is approximately 57 400 km² in extent and is situated at least 120 km from the coastline at its shoreward extent, off St Helena Bay, extending northwards along the western coastline to approximately 230 km offshore Hondeklip Bay (see Figure 1.1). The corner co-ordinates of the area are provided in Table 1.1. The Reconnaissance Permit application area extends across a seafloor depth range of 500 m to 4 000 m. The proposed 3D seismic acquisition would cover a smaller area within the application area although the location has not yet been decided.

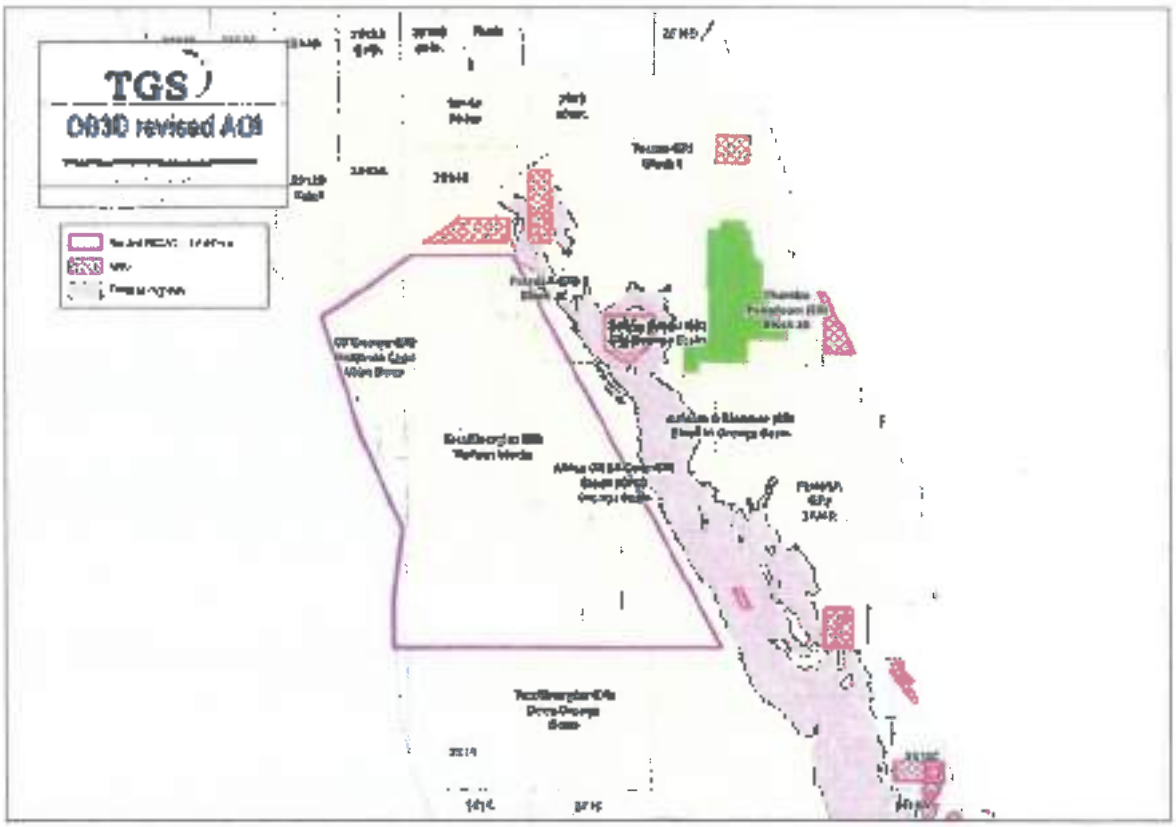

Figure 1.1: Location of the Reconnaissance Permit application area for 3D seismic acquisition.

The survey would be undertaken by a dedicated vessel towing a short array of airguns as well as an array of up to 10 receiving cables up to 8 km in length. It is proposed that the seismic survey would be undertaken during the 2023 / 2024 Austral Summer, subject to granting of the Reconnaissance Permit and vessel availability, over a period of approximately 70 days (excluding weather downtime).

As part of the Environmental Management Plan (EMP) process, Capricorn Marine Environmental (Pty) Ltd (CapMarine) has been appointed by EIMS to undertake an assessment of the impact of the proposed activity on commercial and small-scale fishing operations.

1.2 TERMS OF REFERENCE

The information from this study is intended to inform the EMP process through providing fisheries baseline data for the licence area and surrounds, an expert opinion on the relevant fisheries sectors including proposed mitigation measures to be implemented to manage/mitigate potential impacts of the proposed exploration activities. The specific Terms of Reference (ToR) for the Fisheries Specialist Study are as follows:

- A description of the existing baseline fisheries characteristics within the Reconnaissance Permit area (distribution of fish stocks and commercial, subsistence and recreational fishing activities).
- An introduction presenting a brief background to the study and an appreciation of the requirements stated in the specific terms of reference for the study.
- Details of the approach to the study where activities performed and methods used are presented.
- The specific identified sensitivity of fishing sectors related to the proposed activity.
- Map/s superimposing the proposed survey areas on the spatial distribution of effort expended by each fishing sector.
- Calculation of proportion of fishing ground that coincides with the proposed affected area.
- Assessment of potential impacts on fisheries using prescribed impact rating methodology.
- A description of any assumptions made and any uncertainties or gaps in knowledge.
- Recommendation of mitigation measures, where appropriate.

1.3 PROJECT DESCRIPTION

Seismic surveys are carried out during oil and gas exploration activities in order to investigate subsea geological formations. Seismic surveys are undertaken to collect either 2D or 3D data. 2D surveys are typically applied to obtain regional data from widely spaced survey grids (tens of kilometres) and infill surveys on closer grids (down to a 1 km spacing) are applied to provide more detail over specific areas of interest. 3D surveys are typically applied to promising petroleum prospects to assist in fault interpretation, distribution of sand bodies, estimates of oil and gas in place and the location of exploration wells.

During seismic surveys high-intensity, low frequency sound pulses are generated by an acoustic instrument towed behind a survey vessel, just below the sea surface. The sounds are directed towards the seabed and the seismic signal is reflected by the geological interfaces below the seafloor. The reflected signals are received by an array of receivers or sets of hydrophones towed behind the vessel.

During 3D seismic acquisition, the hydrophones are embedded in multiple streamers. Analyses of the returned signals allow for interpretation of subsea geological formations. The hydrophone streamers must be towed at constant depth, with flotation usually achieved by filling the cables with gel or flexible polymer foam, so that they are neutrally buoyant. To compensate for minor adjustments, Automatic Cable Levellers, or "birds" are used. For the 3D survey, an array of up to 10 hydrophone cables, spaced 150 m apart, will be towed astern of the vessel at a depth of 15 m below the sea surface. The extent of

the towed array would therefore be approximately 1 km wide and 8 km long. The end of each hydrophone streamer will be marked with a tail buoy, to warn shipping about the presence of the cable in the water. The tail buoy also acts as a platform for surface positioning systems so that the cable location can be accurately monitored. Refer to Figure 4.1 for a schematic overview of the seismic vessel towed gear configuration.

During seismic acquisition, the survey vessel would travel along a series of predefined transects of a prescribed survey grid which has been chosen to cross any known or suspected geological structure in the area. The headings of transects would be fixed and reciprocal. During surveying the seismic vessel would travel at a speed of between four and six knots (i.e. 2 to 3 metres per second). As the survey vessel would be restricted in manoeuvrability (a turn radius of 4.5 km is expected), other vessels should remain clear of it. A supply/chase vessel usually assists in the operation of keeping other vessels at a safe distance.

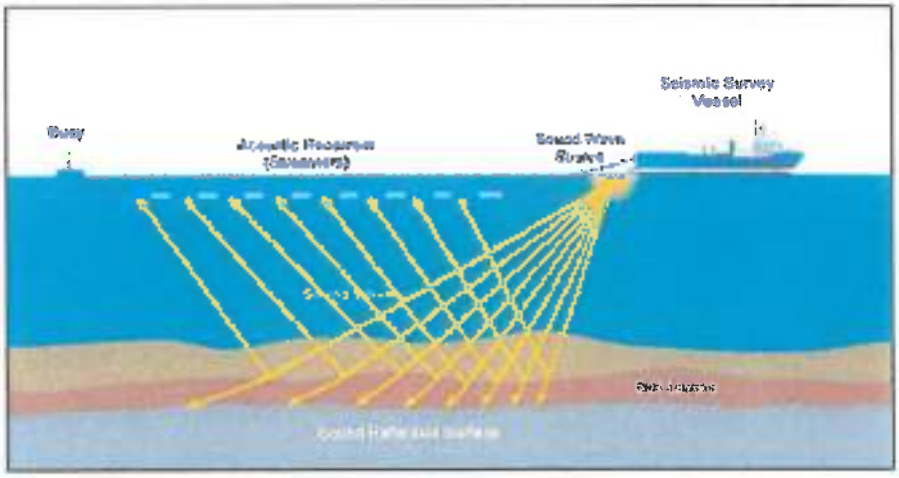

Figure 1.2: Principles of offshore seismic acquisition surveys (from fishsafe.eu).

The anticipated airgun array for the proposed survey would be Sercel G-GUN II 2 820 CUI consisting of 30 active airguns with operating pressures of 2 000 pound-force per square inch. The airgun array would be situated some 50 m behind the vessel at a depth of 8 m below the surface.

During surveying the seismic vessel "fires" the airgun array at regular intervals. Each triggering of a sound pulse is termed a seismic shot, and these are fired at intervals of 6 – 20 seconds (depending on water depth and other environmental characteristics) (Barger & Hamblen 1980). Each seismic shot is usually only between 5 and 30 milliseconds in duration, and despite peak levels within each shot being high, the total energy delivered into the water is low.

Airguns have most of their energy in the 5-300 Hz frequency range, with the optimal frequency required for deep penetration seismic work being 50-60 Hz. The maximum sound pressure levels at the source of airgun arrays in use today in the seismic industry are in the range 230-255 dB re 1 µPa at 1 m, with the majority of their produced energy being low frequency of 10-100 Hz (McCauley 1994; NRC 2003). The location where this level of sound is attained is directly beneath the airgun array, generally near its centre, but the exact location and depth beneath the array are dependent on the detailed makeup of the array, the water depth, and the physical properties of the seafloor (Dragoset 2000).

2 APPROACH AND METHODOLOGY

2.1 DATA SOURCES

The description of the baseline environment in the study area is based on a review and collation of existing information. Catch and effort data were sourced from the Department of Forestry, Fisheries and Environment (Branch: Fisheries) (DFFE) record for the years 2000 to 2019. All data were referenced to a latitude and longitude position and were redisplayed on a 60x60, 10x10 or 5x5 minute grid. Additional information was obtained from the Marine Administration System from DFFE and from the *South Africa, Namibia and Mozambique Fishing Industry Handbook 2019 (47th Edition)*

2.2 ASSESSMENT METHODOLOGY

The proposed Project's potential significant impacts on commercial and small-scale fishing are evaluated in this study. The assessment was focused on the effects caused by 1) exclusion of fishing in the area during the survey operations and 2) effects on catch rates due to noise disturbance in the wider vicinity of the survey area.

The spatial distribution of fishing effort and catch was mapped at an appropriate resolution for each fishing sector (based on the fishing method and resulting area covered by fishing gear). Fishing catch and effort within the vessel survey area (includes proposed seismic acquisition area and extended vessel manoeuvring area) was expressed as a percentage of the total effort and catch figures for each sector. This provided an indication of the proportion of fishing ground that could be affected by the presence of the survey vessel in relation to each fishing sector.

The potential reduction in catch was estimated as:

$$Ct = CT \times \left(\frac{Df}{Dt}\right)$$

where

Ct = catch potentially lost as a result of exclusion from fishing grounds (tons)

CT = total catch recorded as taken in the impact area (in this case the entire survey area) during fishing period (tons)

Df = duration of impact (days)

Dt = total days fished in the survey area during fishing period (dependant on the seasonality of each fishery)

The convention used to evaluate the significance of the impacts is presented in Appendix 1. The sensitivity of the receptor was derived from the baseline information. The impact magnitude, duration and extent was assigned to the pre-mitigation impact (i.e. before additional mitigation measures are applied, but taking into account embedded controls specified as part of the project description) and residual impacts after additional mitigation is applied. Thereafter the impact significance rating was determined as a function of the intensity and the sensitivity of the impact. Significance was assigned to the predicted impact pre-mitigation and post-mitigation (residual) after considering all possible feasible mitigation measures in accordance with the mitigation hierarchy.

2.3 ASSUMPTIONS, LIMITATIONS AND INFORMATION GAPS

The study is based on a number of assumptions and is subject to certain limitations, which should be noted when considering information presented in this report. The validity of the findings of the study is not expected to be affected by these assumptions and limitations:

- The official governmental record of fisheries data was used to display fishing catch and effort relative to the proposed project area. These data are derived from logbooks that are completed by skippers, and it is assumed that there will be a proportion of erroneous data due to mistakes in the capturing of these data into electronic format. The proportion of erroneous data is estimated to be up to 10% of the total dataset and would be primarily related to the accurate recording or transcription of the fishing position (latitude and longitude). Where obvious errors in the reporting of fishing positions were identified these were excluded from the analysis.
- In assessing the impact of the proposed exclusion zone on fishing operations, catch and effort figures are quoted across the entire extent of the proposed survey areas. In practice, the exclusion area would be a moving exclusion zone of approximately 165 km^2 extending around the vessel (based on the required safety clearances shown in Figure 2.1). The approach adopted for this report is likely to be an overestimate of the potential impact on fishing operations which in reality could continue within certain portions of the proposed survey area.
- The acoustic impact is transitory i.e. the sound source moves in space and time as the survey progresses within the target area.
- The effects of seismic sound on the CPUE of fish and invertebrates have been drawn from the findings of international studies. To date there have been no studies focused directly on the species found locally. Although the results from international studies are likely also to be representative for local species, current gaps in knowledge on the topic lead to uncertainty when attempting to accurately quantify the potential loss of catch for each type of fishery. Research into the effects of seismic sound on marine fauna is ongoing.

3 DESCRIPTION OF RECEIVING ENVIRONMENT: FISHERIES BASELINE

3.1 OVERVIEW OF FISHERIES SECTORS

South Africa has a coastline that spans two ecosystems over a distance of 3623 km, extending from the Orange River in the west on the border with Namibia, to Ponta do Ouro in the east on the Mozambique border. The western coastal shelf has highly productive commercial fisheries similar to other upwelling ecosystems around the world, while the East Coast is considerably less productive but has high species diversity, including both endemic and Indo-Pacific species. South Africa's fisheries are regulated and monitored by the DFFE. All fisheries in South Africa, as well as the processing, sale in and trade of almost all marine resources, are regulated under the Marine Living Resources Act, 1998 (No. 18 of 1998) (MLRA).

Approximately 22 different fisheries sectors currently operate within South African waters. Table 3.1 lists these along with ports and regions of operation, catch landings and the number of active vessels and rights holders (2017). The proportional volume of catch and economic value of each of these sectors for 2017 is indicated in Figure 3.1. The primary fisheries in terms of economic value and overall tonnage of landings are the demersal (bottom) trawl and long-line fisheries targeting the Cape hakes (*Merluccius paradoxus* and *M. capensis*) and the pelagic-directed purse-seine fishery targeting pilchard (*Sardinops sagax*), anchovy (*Engraulis encrasicolus*) and red-eye round herring (*Etrumeus whiteheadi*). Highly migratory tuna and tuna-like species are caught on the high seas and seasonally within the South

828

African waters by the pelagic long-line and pole fisheries. Targeted species include albacore (*Thunnus alalunga*), bigeye tuna (*T. obesus*), yellowfin tuna (*T. albacares*) and swordfish (*Xiphias gladius*). The traditional line fishery targets a large assemblage of species close to shore including snoek (*Thyrsites atun*), Cape bream (*Pachymetopon blochii*), geelbek (*Atractoscion aequidens*), kob (*Argyrosomus japonicus*), yellowtail (*Seriola lalandi*) and other reef fish. Crustacean fisheries comprise a trap and hoop net fishery targeting West Coast rock lobster (*Jasus lalandii*), a line trap fishery targeting the South Coast rock lobster (*Palinurus gilchristi*) and a trawl fishery based solely on the East Coast targeting penaeid prawns, langoustines (*Metanephrops andamanicus* and *Nephropsis stewarti*), deep-water rock lobster (*Palinurus delagoae*) and red crab (*Chaceon macphersoni*). Other fisheries include a mid-water trawl fishery targeting horse mackerel (*Trachurus trachurus capensis*) predominantly on the Agulhas Bank (South Coast) and a hand-jig fishery targeting chokka squid (*Loligo vulgaris reynaudi*) exclusively on the South Coast. In addition to commercial sectors, recreational fishing occurs along the coastline comprising shore angling and small, open boats generally less than 10 m in length. The commercial and recreational fisheries are reported to catch over 250 marine species, although fewer than 5% of these are actively targeted by commercial fisheries, which comprise 90% of the landed catch.

Most commercial fish landings must take place at designated fishing harbours. For the larger industrial vessels targeting hake, only the major ports of Saldanha Bay, Cape Town, Mossel Bay and Port Elizabeth are used. On the West Coast, St. Helena Bay and Saldanha Bay are the main landing sites for the small pelagic fleets. These ports also have significant infrastructure for the processing of anchovy into fishmeal as well as the canning of sardine. Smaller fishing harbours on the West / South-West Coast include Port Nolloth, Hondeklip, Doringbaai, Lamberts Bay, Hout Bay and Gansbaai harbours. On the East Coast, Durban and Richards Bay are deployment ports for the crustacean trawl and large pelagic longline sectors. There are more than 230 small-scale fishing communities on the South African coastline (DAFF, 2016). Small-scale fisheries operate in the nearshore environment. Recreational fisheries comprise shore-based, estuarine and boat-based line fisheries as well as spearfishing and net fisheries, including cast, drag and hoop net techniques.

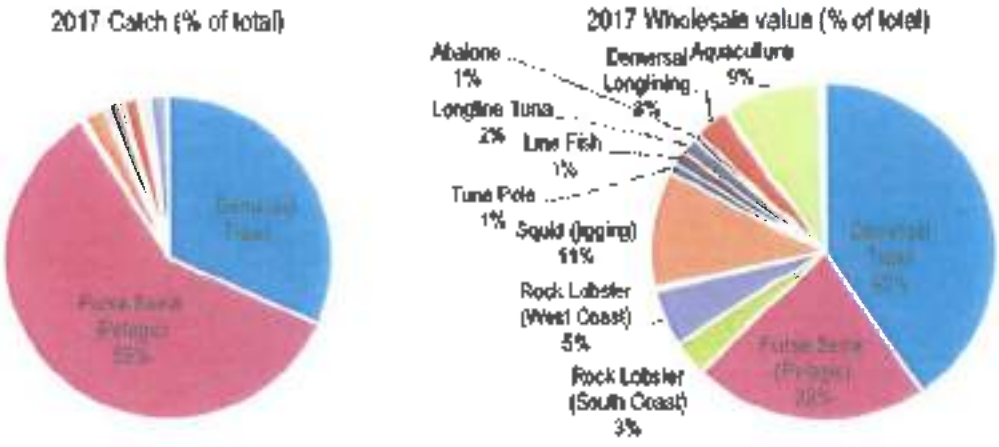

Figure 3.1: Pie chart showing percentage of landings by weight (left) and wholesale value (right) of each commercial fishery sector as a contribution to the total landings and value for all commercial fisheries sectors combined (2017). Source: DEFF, 2019.

Table 3.1: South African offshore commercial fishing sectors: wholesale value of production in 2017 (adapted from DEFF, 2019).

Sector	No. of Rights Holders (Vessels)	Catch (tons)	Landed Catch /Sales (tons)	Wholesale Value of Production (rm) 2017 (R 000)	% of Total Value

3.2 SPAWNING AND RECRUITMENT OF FISH STOCKS

The South African coastline is dominated by seasonally variable and sometimes strong currents, and most species have evolved selective reproductive patterns to ensure that eggs and larvae can enter suitable nursery grounds situated along the coastline. Three nursery grounds can be identified in South African waters, viz the Natal Bight, the Agulhas Bank and the inshore Western Cape coasts. Each is linked to a spawning area, a transport and/or recirculation mechanism, a potential for deleterious offshore or alongshore transport and an enriched productive area of coastal or shelf-edge upwelling (Hutchings et al., 2002).

Hake, sardines, anchovy and horse mackerel are mostly serial, broadcast spawners, producing large numbers of eggs sporadically that are widely dispersed in ocean currents (Hutchings et al., 2002). The principal commercial fish species undergo a critical migration pattern in the Agulhas and Benguela ecosystems. Adults spawn on the Agulhas Bank between the shelf-edge upwelling and the cold-water ridge, where copepod availability is highest (Crawford 1980; Hutchings 1994; Roel & Armstrong 1991; Hutchings et al. 2002). The spawn products are thought to move southwards from the central Agulhas Bank and then may drift northwards in the Benguela current across the shelf and up the west coast, or inshore and eastwards towards the south coast. As the eggs drift, hatching takes place followed by larval development. Settlement of larvae occurs in the inshore areas, in particular the bays that are used as nurseries, from October to March. In the southern Benguela system, juveniles shoal and then begin a southward migration down the west coast – it is at this stage that anchovy and sardine are targeted by the small pelagic purse seine fishery. Juveniles of demersal species such as hake are thought to move from a pelagic phase and to systematically migrate to the seafloor (a vertical migration) and then as they mature and grow in size, move offshore into deeper water where they are targeted by commercial fisheries (in hake this occurs in their third year of growth and is referred to as "recruiting" to the fishery).

Spawning of key species exploited by commercial fishery sectors off the West Coast are presented below (Hutchings et al. 2002):

- Hake, snoek and round herring move to the western Agulhas Bank and southern west coast to spawn during key periods (late winter to early spring), when losses due to offshore drift are at a minimum and eggs and larvae drift northwards and inshore to the west coast nursery grounds.
- Hake are serial spawners and are reported to spawn throughout the year with peaks in October/November and March/April (Johann Augustyn, SADSTIA and Dave Japp, CapMarine pers com.). During these periods there is a greater concentration of drifting eggs and larvae compared to other months. Spawning of the shallow-water hake occurs primarily over the shelf (<200 m) whereas that by the deep-water hake occurs off the shelf.
- Horse mackerel spawn over the east/central Agulhas Bank during winter months but are also concentrated on the eastern part of the bank most months in feeding aggregations. Juveniles occur close inshore off the southern Cape coastline and west coast nursery habitats.
- Anchovies are known to spawn on the western, central and eastern Agulhas Bank, from October to March with spawning peaking during October to January (van der Lingen and Huggett, 2003) and some shifts to the west coast in years when Agulhas Bank water intrudes strongly north of Cape Point (van der Lingen *et al.*, 2001 in Hutchings *et al.*, 2002)
- Genomic and transcriptomic analyses have shown that there are two stocks of sardine off South Africa; the Cool Temperate Sardine (CTS) off the west coast and Warm Temperate Sardine (WTS) off the south coast, with some mixing (in both directions) between the two (Teske *et al.* 2021). Sardines spawn on the western, central and eastern Agulhas Bank, and also off the west coast

5628

north of Cape Point. Sardine eggs are found throughout the year, but spawning occurs from August to February (spring-summer) for the CTS off the west coast, and from June to November (winter-spring) for WTS off the south coast. There is an intense seasonal movement of sardine eastwards (the "sardine run") that occurs in mid-winter and which is associated with westerly frontal systems driving fish inshore in counter currents. And whilst sardine eggs are found off the east coast from June to December (see Connell 2010 AJMS 32(2)), the KwaZulu-Natal sardine run is not the spawning migration of a third stock but a navigation error by CTS.

- Squid (*Loligo* spp.) spawn in the nearshore zone on the eastern Agulhas Bank, principally in shallow waters (<50 m) between Knysna and Gqeberha. Their distribution and abundance are erratic and linked to temperature, turbidity, and currents (Augustyn et al. 1994; Schön et al. 2002). This niche area on the eastern Agulhas Bank optimises their spawning and early life stage as nowhere else on the shelf are both bottom temperature and bottom dissolved oxygen simultaneously at optimal levels for egg development (Roberts 2005; Oosthuizen & Roberts 2009). The greatest concentration of their food (copepods) tends to be found further west in the cold-water ridge on the central Agulhas Bank (Roberts & van den Berg 2002). Squid are not broadcast spawners but instead they lay benthic egg sacs. The paralarvae that hatch from the sacs are distributed close inshore and juveniles are dispersed over the entire shelf region of the Agulhas Bank. Larvae and juveniles are carried offshore and westwards (via the Benguela jet) to feed and mature, before returning to the spawning grounds to complete their lifecycle (Olyott et al. 2007).
- Snoek spawning occurs offshore during winter-spring (June to October), along the shelf break (150-400 m) of the western Agulhas Bank and the South African west coast. Prevailing currents transport eggs and larvae to a primary nursery ground north of Cape Columbine and to a secondary nursery area to the east of Danger Point; both shallower than 150 m. Juveniles remain on the nursery grounds until maturity, growing to between 33 and 44 cm in the first year (3.25 cm/month). Onshore-offshore distribution (between 5- and 150-m isobaths) of juveniles is determined largely by prey availability and includes a seasonal inshore migration in autumn in response to clupeoid recruitment. Adults are found throughout the distribution range of the species, and although they move offshore to spawn - there is some southward dispersion as the spawning season progresses - longshore movement is apparently random and without a seasonal basis (Griffiths, 2002; refer to Figure 3.3).
- The inshore area of the Agulhas Bank, especially between the cool water ridge and the shore, serves as an important nursery area for numerous linefish species (e.g. elf *Pomatomus saltatrix*, leervis *Lichia amia*, geelbek *Atractoscion aequidens*, carpenter *Argyrozona argyrozona*) (Wallace et al. 1984; Smale et al. 1994). A significant proportion of these eggs and larvae originate from spawning grounds along the east coast, as adults undertake spawning migrations along the South Coast into KwaZulu-Natal waters (van der Elst 1976, 1981; Griffiths 1997; Garratt 1988; Beckley & van Ballegooyen 1992). The eggs and larvae are subsequently dispersed southwards by the Agulhas Current, with juveniles occurring on the inshore Agulhas Bank, using the area between the cold-water ridge and the shore as nursery grounds (van der Elst 1976, 1981; Garratt 1988). In the case of the carpenter, a high proportion of the reproductive output comes from the central Agulhas Bank and the Tsitsikamma Marine Protected Area (MPA), and two separate nursery grounds appear to exist, one near Gqeberha and a second off the deep reefs off Cape Agulhas, with older fish spreading eastwards and westwards (van der Lingen et al. 2006).

Table 3.3 shows known spawning periods of key commercial species off the West Coast of South Africa.

Table 3.3: Table showing known spawning periods of key commercial species off the West Coast of South Africa.

3.3 COMMERCIAL FISHING SECTORS

3.3.1 DEMERSAL TRAWL

The primary fisheries in terms of highest economic value are the demersal (bottom) trawl and longline fisheries targeting the Cape hakes (*Merluccius paradoxus* and *M. capensis*). Secondary species include a large assemblage of demersal fish of which monkfish (*Lophius vomerinus*), kingklip (*Genypterus capensis*) and snoek (*Thyrsites atun*) are the most commercially important. The demersal trawl fishery comprises an offshore (deep-sea) and inshore fleet, which differ primarily in terms of vessel capacity and the areas in which they operate. The wholesale value of catch landed by the inshore and offshore demersal trawl sectors, combined, during 2017 was R3.982 Billion, or 40.5% of the total value of all fisheries combined. The 2022 TAC for hake is set at 132 154 tons, of which 84% and 6% is allocated to the offshore and inshore trawl sectors, respectively. (The remaining 10% is allocated to the hake demersal longline sector – refer to section 3.3.3).

The annual TAC limits and landings of hake (both species) by the trawl and longline sectors is listed in Table 3.3. A time-series of total hake catch as well as hake catch by sector is shown in Figure 3.6.

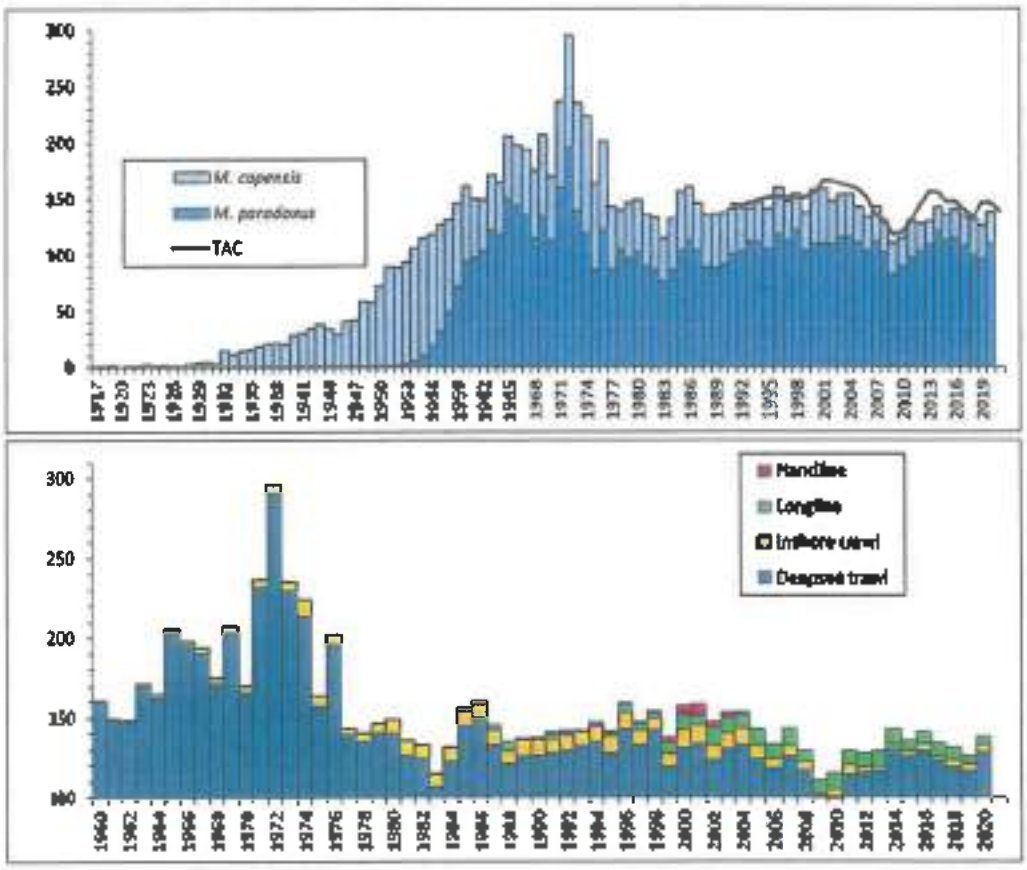

Figure 3.6: (top) Total catches ('000 tonnes) of Cape hakes split by species over the period 1917–2020 and the TAC set each year since the 1991. (bottom) Catches of Cape hakes per fishing sector for the period 1960–2020. Prior to 1960, all catches are attributed to the deep-sea trawl sector. Note that the vertical axis commences at 100 000 tonnes to better clarify the contributions by each sector. (Source DEFF, 2022)

Table 3.4: Annual total allowable catch (TAC) limits and catches (tons) of the two species of hake by the hake-directed fisheries on the West (WC) and South (SC) coasts (Adapted from DEFF, 2020[1]).

[1] FISHERIES/2021/OCT/SWG-DEM/21rev

2021	139109
2022	132184

The offshore fishery is comprised of 45 vessels operating from most major harbours on both the West and South Coasts. On the West and South-West Coasts, these grounds extend in a continuous band along the shelf edge approximately between the 200 m and 1 000 m bathymetric contours although most effort is in the >300 m to 600 m depth range. Monkfish-directed trawlers tend to fish shallower waters than hake-directed vessels on mostly muddy substrates. Trawl nets are generally towed parallel to the depth contours (thereby maintaining a relatively constant depth) in a north-westerly or south-easterly direction. Trawlers also target fish aggregations around bathymetric features, in particular seamounts and canyons, where there is an increase in seafloor slope and in these cases the direction of trawls follow the depth contours. The deep-sea sector is prohibited from operating in waters shallower than 110 m or within five nautical miles of the coastline. Fishing activity occurs year-round.

The inshore fishery consists of 31 vessels, which operate on the South Coast mainly from the harbours of Mossel Bay and Port Elizabeth. Inshore grounds are located on the Agulhas Bank and extend towards the Great Kei River in the east. Vessels also target sole close inshore between Struisbaai and Mossel Bay, between the 50 m and 80 m isobaths. Hake is targeted further offshore in traditional grounds between 100 m and 200 m depth in fishing grounds known as *the Blues* located on the Agulhas Bank.

Otter trawling is the main trawling method used in the South African hake fishery. This method of trawling makes use of trawl doors (also known as otter boards) that are dragged along the seafloor ahead of the net maintaining the horizontal net opening. Bottom contact is made by the footrope and by long cables and bridles between the doors and the footrope. Behind the trawl doors are bridles connecting the doors to the wings of the net (to the ends of the footrope and headrope). A headline, bearing floats and the weighted footrope (that may include rope, steel wire, chains, rubber discs, spacers, bobbins or weights) maintain the vertical net opening. The "belly", "wings" and the "cod-end" (the part of the net that retains the catch) may contact the seabed (see Figure 3.8). The configuration of trawling gear is similar for both offshore and inshore vessels however inshore vessels are smaller and less powerful than those operating within the offshore sector. The offshore fleet is segregated into wetfish and freezer vessels which differ in terms of the capacity for the processing of fish at sea and in terms of vessel size and capacity. While freezer vessels may work in an area for up to a month at a time, wetfish vessels may only remain in an area for about a week before returning to port. Wetfish vessels range between 24 m and 56 m in length while freezer vessels are usually larger, ranging up to 90 m in length. Inshore vessels range in length from 15 m to 40 m. Trips average three to five days in length and all catch is stored on ice.

Figure 3.7: Photograph of MFV *Harvest Mzansi*, a wetfish vessel operating in the South African offshore demersal trawl sector (source: www.sadatsa.co.za).

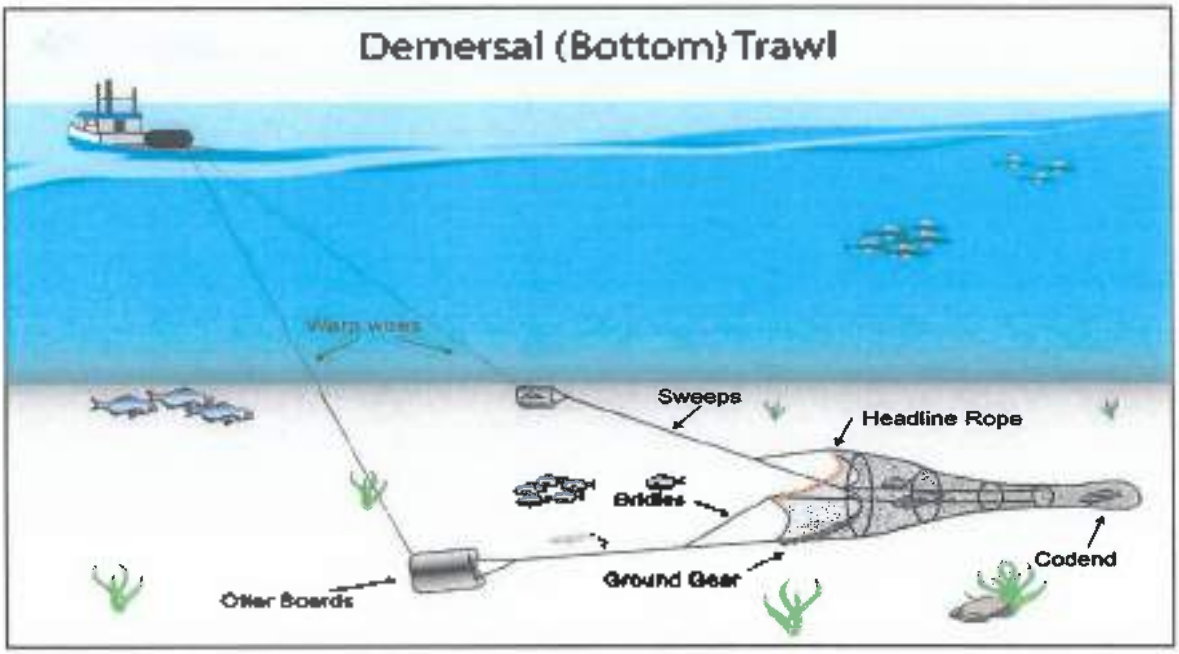

Figure 3.8: Typical gear configuration used by offshore demersal trawlers targeting hake (Source: www.afma.gov.au/fisheries-management/methods-and-gear/trawling).

The activity of the fishery is restricted by permit condition to operating within the confines of a historical "footprint" – an area of approximately 57 300 km^2 and 17 000 km^2 for the offshore and inshore fleets, respectively. Offshore trawlers operate along the west coast along the shelf break between approximately Hondeklipbaai and the southern tip of the Agulhas Bank between the 200 m and 750 m bathymetric contours, with sporadic trawls to a maximum depth of 900 m. The Reconnaissance Permit extends offshore of fishing grounds referred to as the "North Grounds" (Sink et. al, 2012). These grounds are characterised by sandy and muddy sand, with isolated patches of hard ground. The area has been trawled since the 1960's commencing on shallower grounds and with effort extending into deeper waters with the advancement of fishing technologies over time.

At it's closest point the demersal trawl footprint is situated approximately 5 km offshore of the area fished around the slopes of the submarine feature Childs Bank (referred to by the fishing industry as the "karbonkel") off Hondeklipbaai. The demersal trawl footprint is situated at least 10 km inshore of the eastern extent of the Reconnaissance Permit area towards the productive fishing grounds between Lamberts Bay and Saldanha Bay. Figure 3.9 shows the demersal trawling footprint and recent effort off the west coast of South Africa and in relation to the Reconnaissance Permit application area.

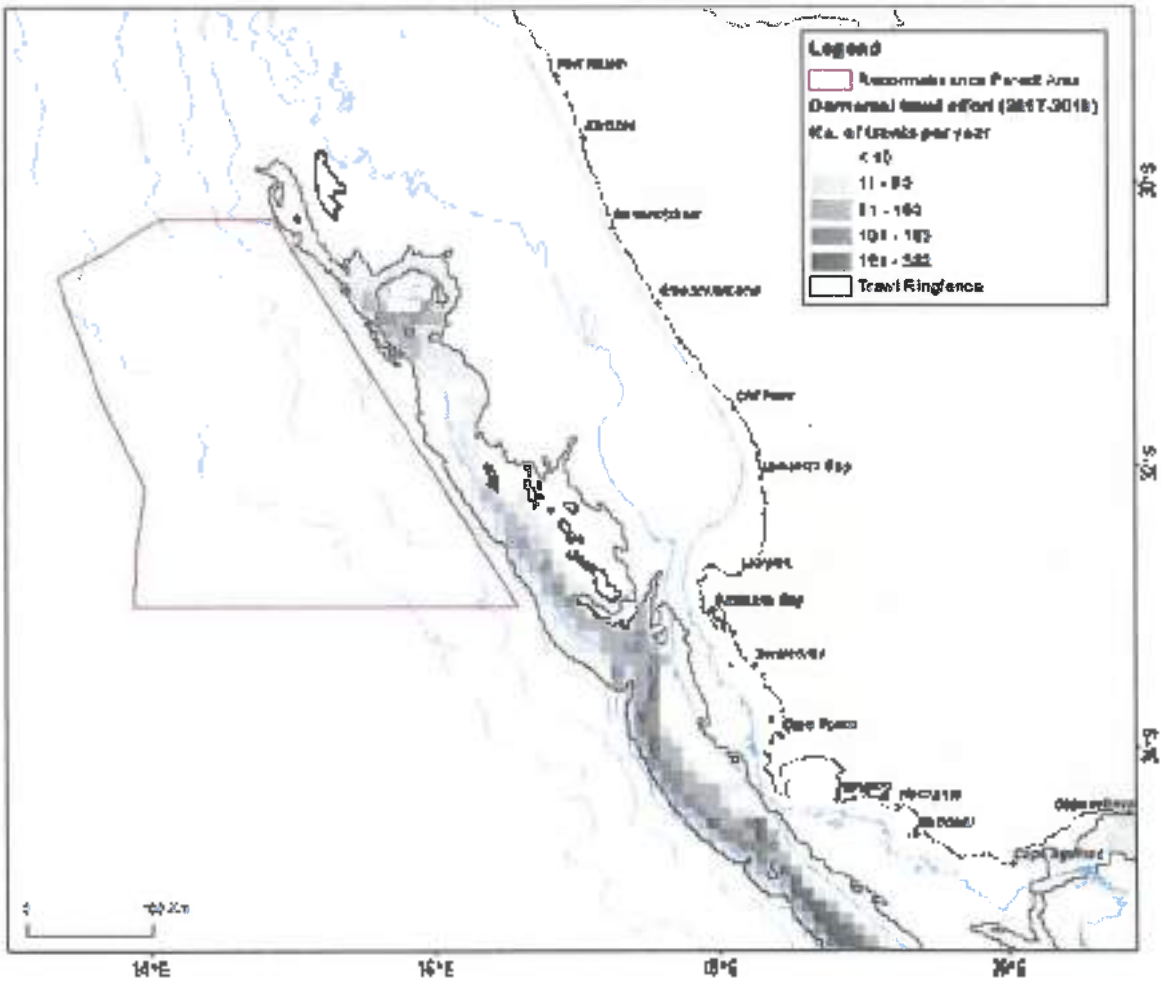

Figure 3.9: Overview of the trawl ringfence and the spatial distribution of fishing effort expended by the demersal trawl sector in relation the Reconnaissance Permit application area.

3.3.2 MIDWATER TRAWL

The midwater trawl fishery targets adult Cape horse mackerel (*Trachurus capensis*), which aggregate in highest concentration on the Agulhas Bank. Cape horse mackerel are semi-pelagic shoaling fish that occur on the continental shelf off southern Africa from southern Angola to the Wild Coast. Off South Africa, adult horse mackerel are currently more abundant off the South Coast than the West Coast. Horse mackerel yield a low-value product and are a source of cheap protein (DEFF, 2020).

This sector comprises six vessels and 34 rights holders which landed a total catch of 19 555 in 2019. Refer to Figure 3.10 for the catches and TACs for the midwater trawl fishery between 1996 and 2018. The fleet is split between dual rights holders who fish horse mackerel on hake-directed trawlers and

FZ28

others that combine their allocation on a single large midwater trawl vessel (the MFV *Desert Diamond* – refer to Figure 3.11). Dual rights holders fishing only occurs if horse mackerel availability is high when fishing for hake at which point that may switch from bottom trawl to midwater trawl. The amounts of horse mackerel caught by these vessels is a relatively small component of the horse mackerel TAC. Those horse mackerel rights holders that do not have hake rights or who do not have a suitable vessel to catch horse mackerel allow their share of the horse mackerel to be caught on a single large midwater trawler. This facilitates the economic use of a single large vessel that can more efficiently catch their horse mackerel allowing the vessels to fish year round. The area fished by this vessel is restricted largely (but not exclusively) to water deeper than 110 m or more than 20 nm from the coast and in an area east of Cape Point. The dual vessels may fish in a broader area, mostly on or near the hake fishing grounds.

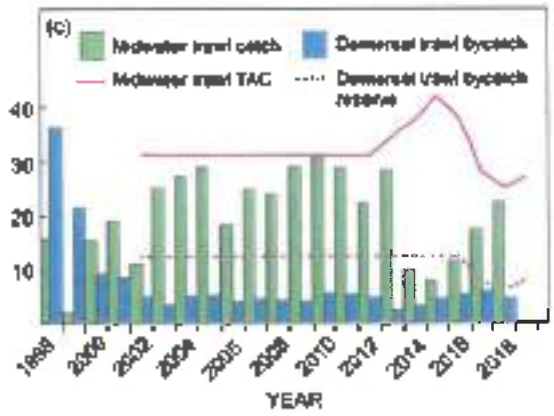

Figure 3.10: Trawl catches (tons, 1998 – 2018) split into the demersal and midwater trawl components. The midwater trawl TAC (solid line) and demersal trawl bycatch reserve (dashed line) are also shown (Source: DEFF, 2020).

Figure 3.11: Photograph of MFV Desert *Diamond* (midwater trawler).

Midwater trawl is defined in the Marine Living Resources Act (No. 18 of 1998) (MLRA) as any net which can be dragged by a fishing vessel along any depth between the seabed and the surface of the sea without continuously touching the bottom. In practice, midwater trawl gear does occasionally come into contact with the seafloor. Midwater trawling gear configuration is similar to that of demersal trawlers, except that the net is manoeuvred vertically through the water column (refer to Figure 3.12 for a schematic diagram of gear configuration). The towed gear may extend up to 1 km astern of the vessel and comprises trawl warps, net and cod end. Trawl warps are between 32 mm and 38 mm in diameter. The trawl doors (3.5 t each) maintain the net opening which ranges from 120 to 130 m in width and from 40 m to 80 m in height. Weights in front of, and along the ground-rope provide for vertical opening of the trawl. The cable transmitting acoustic signal from the net sounder might also provide a lifting force that maximizes the vertical trawl opening. To reduce the resistance of the gear and achieve a large opening, the front part of the trawls are usually made from very large rhombic or hexagonal meshes. The use of nearly parallel ropes instead of meshes in the front part is also a common design. Once the gear is deployed, the net is towed for several hours at a speed of 4.6 to 6.8 knots predominantly parallel with the shelf break.

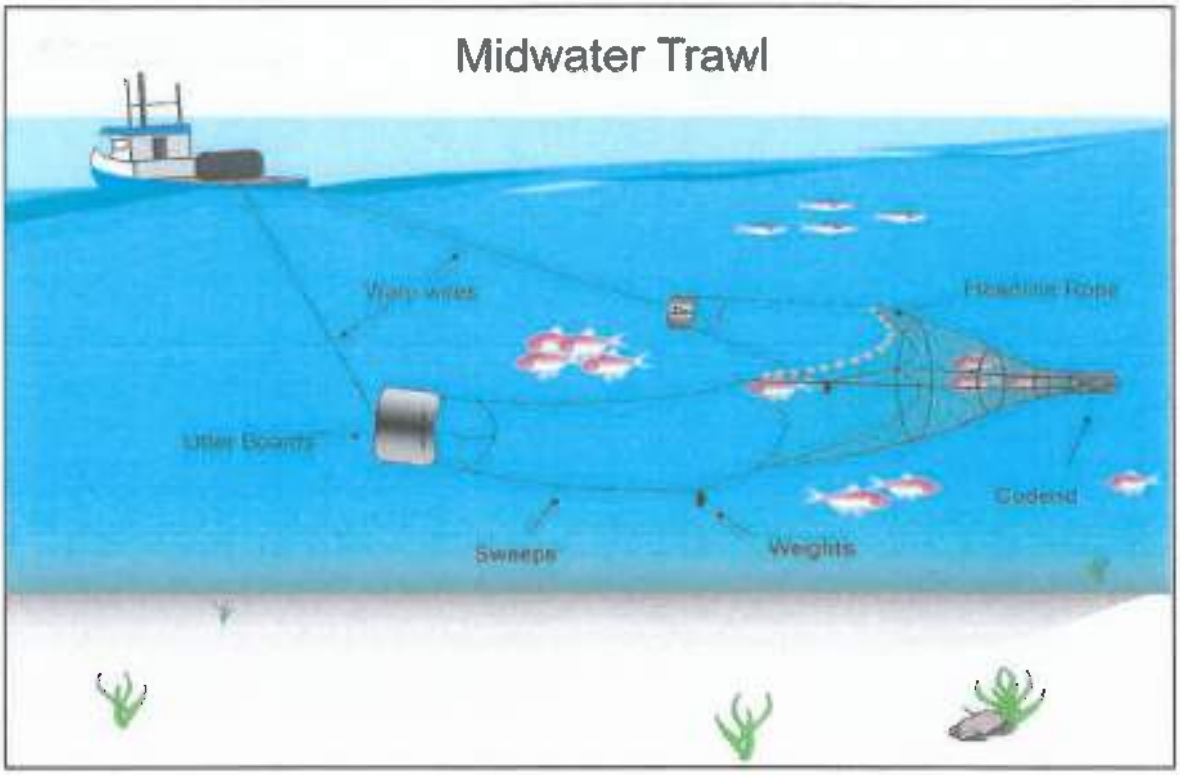

Figure 3.12: Schematic diagram showing the typical gear configuration of a midwater trawler
Source: www.afma.gov.au/fisheries-management/methods-and-gear/trawling

The fishery operates predominantly on the edge of the Agulhas Bank, where shoals are found in commercial abundance. Fishing grounds off the South Coast are situated along the shelf break and three dominant areas can be defined. The first lies between 22 °E and 23 °E at a distance of approximately 70 nm offshore from Mossel Bay and the second extends from 24 °E to 27 °E at a distance of approximately 30 nm offshore. The third area lies to the south of the Agulhas Bank 21 °E and 22 °E. These grounds range in depth from 100 m to 400 m and isolated trawls are occasionally recorded up to 650 m. Since 2017, DFFE has permitted experimental fishing to take place westward of 20°E.

Figure 3.13 shows the spatial extent of midwater trawls undertaken between 2017 and 2019 in relation to the Reconnaissance Permit application area. Sector activity off the West Coast takes place predominantly south of Cape Town at a depth range of between 120 m and 560 m. There is no overlap between midwater trawl grounds and the Reconnaissance Permit application area which is situated at least 30 km from the closest fishing location and 150 km from the main fishing areas.

F.28

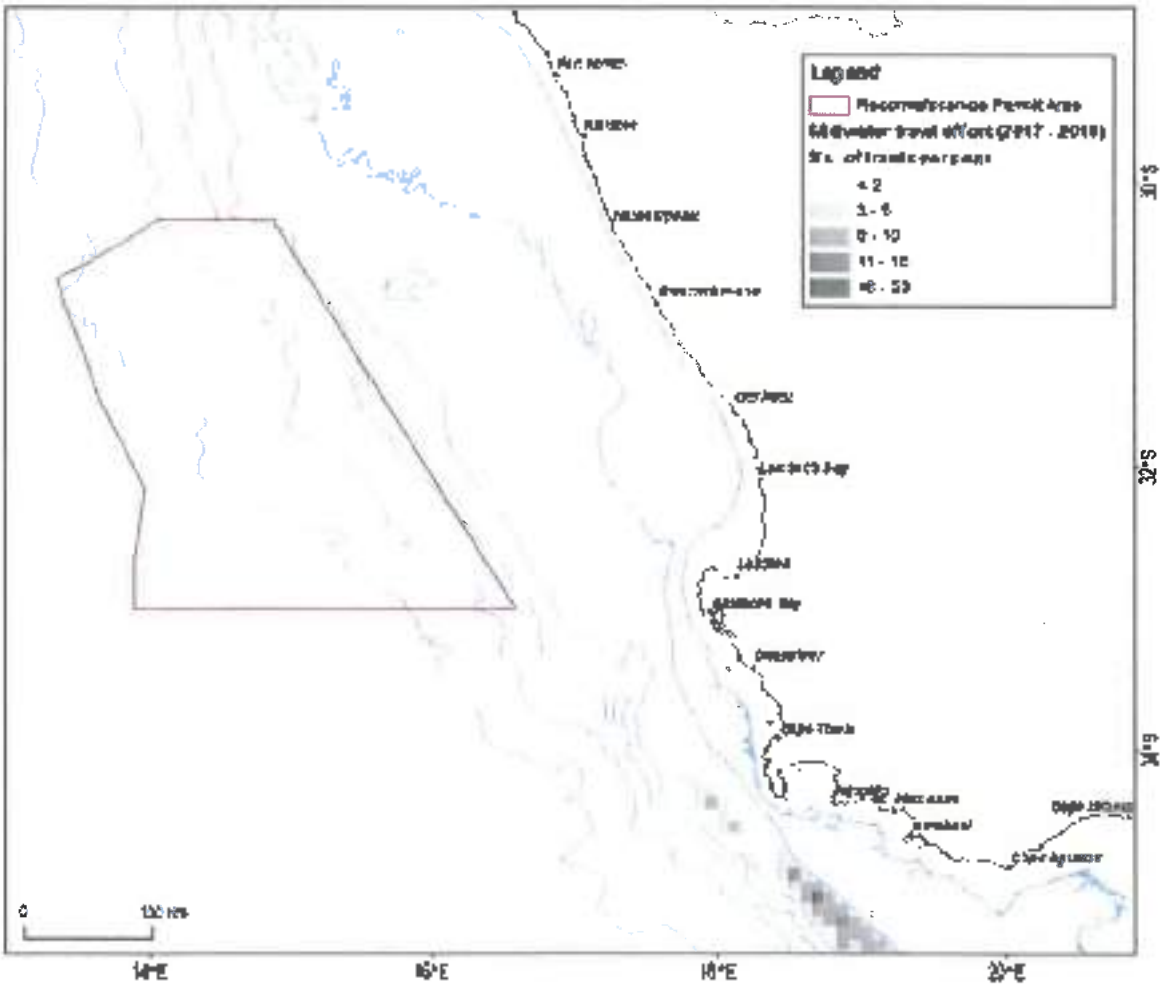

Figure 3.13: DFFE's catch reporting grid system and the spatial distribution of fishing effort expended by the midwater trawl sector in relation to the Reconnaissance Permit application area.

3.3.3 DEMERSAL HAKE LONGLINE

Like the demersal trawl fishery, the target species of the longline fishery is the Cape hakes, with a small non-targeted commercial by-catch that includes kingklip. In 2017, 8113 tons of catch was landed with a wholesale value of R319.2 Million, or 3.2% of the total value of all fisheries combined. Landings of 8 230 tons were reported in 2016. Refer to Table 3.3 for the landings of hake by the demersal longline fishery over the period 2010 to 2020.

A demersal longline vessel may deploy either a double or single line which is weighted along its length to keep it close to the seafloor. Steel anchors, of 40 kg to 60 kg, are placed at the ends of each line to anchor it, and are marked with an array of floats. If a double line system is used, top and bottom lines are connected by means of dropper lines. Since the top-line (polyethylene, 10 – 16 mm diameter) is more buoyant than the bottom line, it is raised off the seafloor and minimizes the risk of snagging or fouling. The purpose of the top-line is to aid in gear retrieval if the bottom line breaks at any point along the length of the line. Lines are typically between 10 km and 20 km in length, carrying between 6 900 and 15 600 hooks each. Baited hooks are attached to the bottom line at regular intervals (1 to 1.5 m) by means of a snood. Gear is usually set at night at a speed of between five and nine knots. Once

deployed the line is left to soak for up to eight hours before it is retrieved. A line hauler is used to retrieve gear (at a speed of approximately one knot) and can take six to ten hours to complete. A schematic representation of the gear configuration used by the demersal longline fleet is shown in Figure 3.14.

Currently 64 hake-directed vessels are active within the fishery, most of which operate from the harbours of Cape Town and Hout Bay. Fishing grounds are similar to those targeted by the hake-directed trawl fleet. The hake longline footprint extends down the west coast from approximately 150 km offshore of Port Nolloth (15°E, 29°S). It lies inshore to the south of St Helena Bay moving offshore once again as it skirts the Agulhas Bank to the south of the country (21°E, 37°S). Along the South Coast the footprint moves inshore again towards Mossel Bay. The eastern extent of the footprint lies at approximately (26°E, 34.5°S). Lines are set parallel to bathymetric contours, along the shelf edge up to the 1 000 m depth contour in places. The more patchy nature of effort in the north western extents of the footprint and the eastern edge of the Agulhas Bank may be attributed to proximity to fishing harbours. Fishing activity within the area occurs year-round with slightly lower levels during winter.

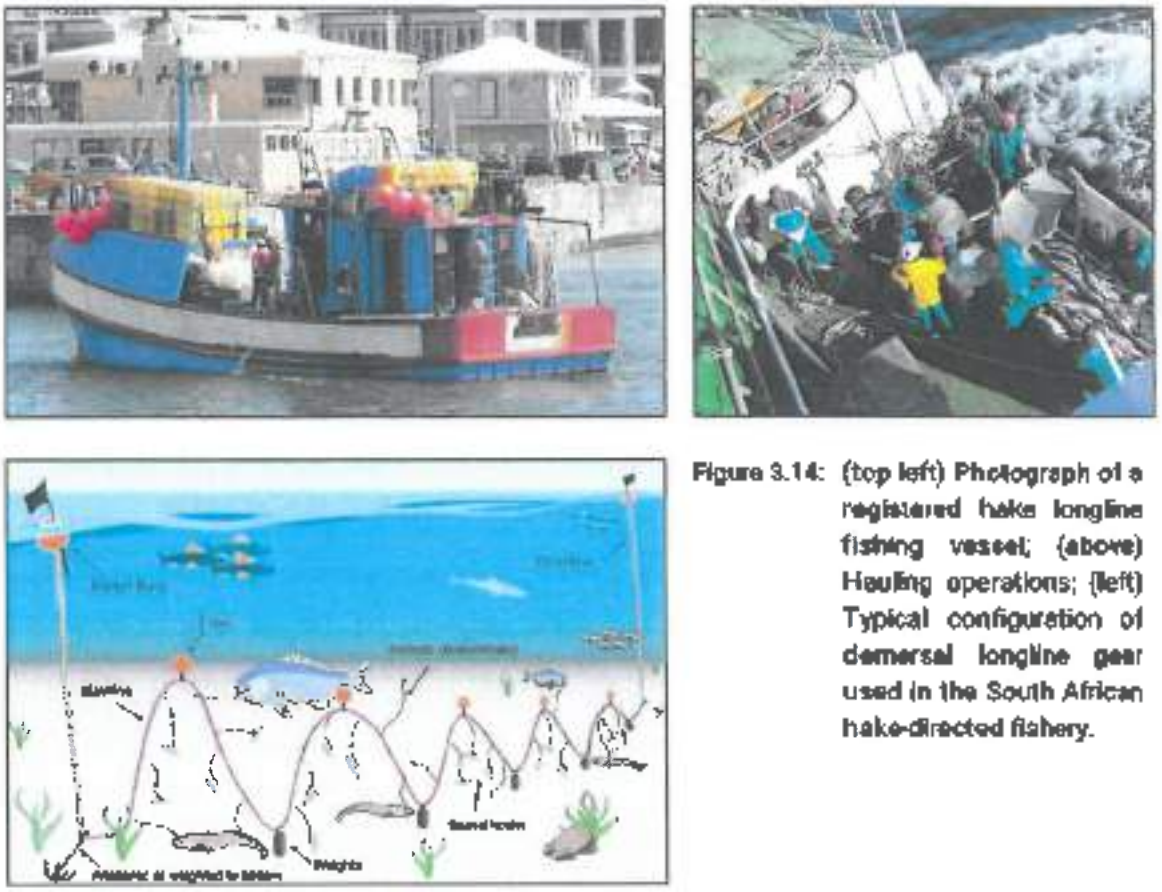

Figure 3.14: (top left) Photograph of a registered hake longline fishing vessel; (above) Hauling operations; (left) Typical configuration of demersal longline gear used in the South African hake-directed fishery.

Figure 3.15 shows the spatial distribution of demersal longline fishing areas in relation to the Reconnaissance Permit application area. Fishing effort takes place between the 100 m and 750 m bathymetric contours but the majority of effort takes place within the depth range 200 m to 650 m. There is no overlap between demersal hake-directed longline grounds and the Reconnaissance Permit application area, which is situated approximately 12 km offshore of the closest fishing locations.

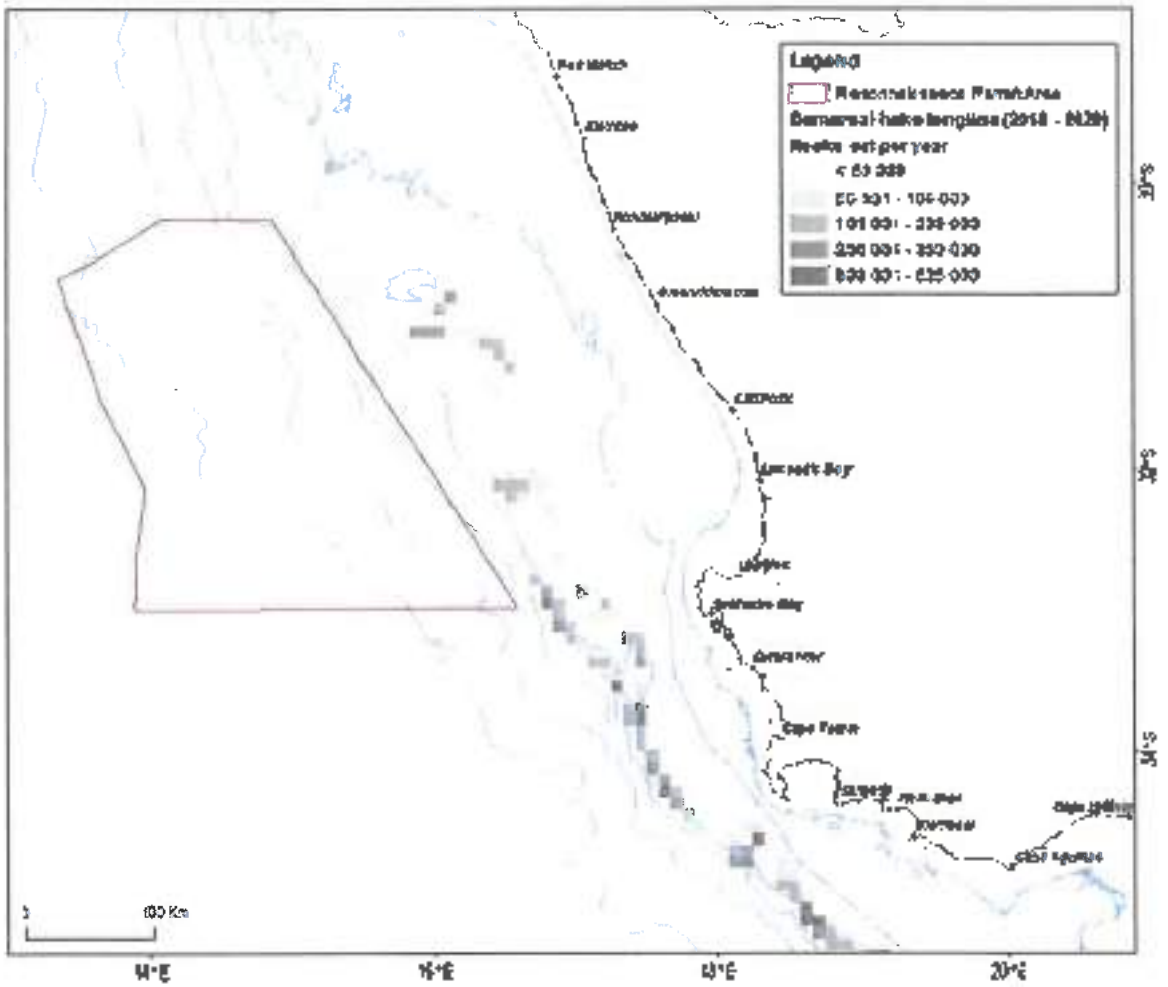

Figure 3.16: Spatial distribution of fishing effort expended by the hake-directed demersal longline sector in relation to the Reconnaissance Permit application area.

3.3.4 DEMERSAL SHARK LONGLINE

The shark longline sector formally commenced in 1991 when 30 permits were issued initially to target both demersal and pelagic sharks (pelagic sharks are those living in the water column, often occurring further offshore). In 2005 the dual targeting of demersal and pelagic sharks under the same permit was discontinued and the sector became an exclusive demersal shark longline fishery reduced to eleven Right Holders in 2004 and just six in 2006. The demersal shark longline fishery is permitted to operate in coastal waters from the Orange River on the West Coast to the Kei River on the East Coast, but fishing rarely takes place north of Table Bay. Vessels are typically <30 m in length and use nylon monofilament Lindgren Pitman spool systems to set weighted longlines baited with up to 2 000 hooks (average = 917 hooks). The fishery operates in waters generally shallower than 100 m, and uses bottom-set gear to target predominantly soupfin sharks and smoothhound sharks. Following an initial period of adjustment to catching and marketing demersal sharks, catches of soupfin and smoothhound sharks started increasing in 2006, and reporting became more reliable. As the majority of Right Holders own additional Rights in other fisheries, the number of active vessels fluctuates over the year but rarely exceeds four vessels operating at the same time. Annual landings have fluctuated widely due to variation in demand and price. Rights are due to be re-allocated during the fishing Rights allocation process in 2021/2022.

The commercial-scale exploitation of sharks began in the 1930s around traditional fishing villages in the Western Cape. This fishery used handlines and targeted inshore demersal sharks for their livers to be used in the production of Vitamin A oil. By the 1940s, catches of soupfin sharks had declined (Davies 1964) as targeting shifted. To date, this Western Cape soupfin fishery has not recovered to historical catch levels. To compensate for declining catch rates of high-value line fish species, a rapid increase was seen in shark catches between 1990 and 1993. After 2000, species-specific reporting came into effect and sharks continued to constitute a large proportion of the livelihood of these fishers around South Africa, with the establishment of a number of dedicated shark processing facilities. Shark catches by the line fishery since the 1990s have typically fluctuated in response to the availability of higher priced line fish species and market influences. Species targeted include soupfin sharks, smoothhound sharks, dusky sharks *Carcharhinus obscurus*, bronze whaler sharks *C. brachyurus*, and various skate species. Table 3.4 lists 2018 landings of the main demersal shark and skate species caught by line.

Table 3.5: Total catches per FAO area of demersal shark (2018).

Species	Catch by FAO Area (kg)			Total
	1.6	2.1	2.2	
Soupfin shark	7	2017	365	2389
Smoothhound shark	6	4244	5340	9591
Bronze shark	6	384	0	390
St. Joseph shark	0	112	33	144
Skate	0	145	444	589
Total	19	6902	6183	13103

Figure 3.16 shows the spatial distribution of shark-directed demersal longline catch between 2017 and 2019 in relation to the Reconnaissance Permit application area. Recent fishing activity shows effort occurs East of Cape Point, inshore of the 100 m depth contour and at least 230 km SE of the Reconnaissance Permit area at closest point. There is no overlap of the demersal longline sector with the Reconnaissance Permit area.

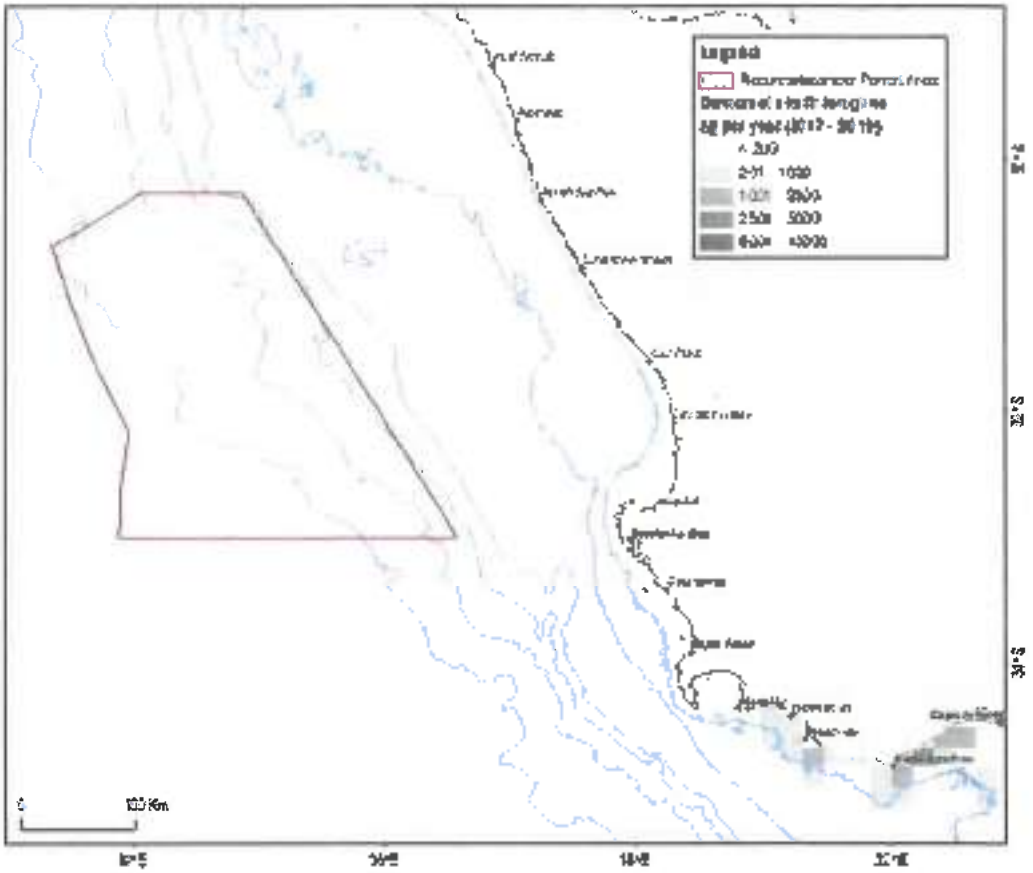

Figure 3.16: An overview of the spatial distribution of fishing effort expended by the shark-directed demersal longline sector in relation to the Reconnaissance Permit application area.

3.3.5 SMALL PELAGIC PURSE-SEINE

The pelagic-directed purse-seine fishery targets anchovy (*Engraulis encrasicolus*) and adult sardine (*Sardinops sagax*). Right Holders may also target round herring (*Etrumeus whiteheadi*) and meso pelagic species (Lantern and Lightfish combined) which have industry precautionary upper catch limits (PUCLs) – currently set at 100 000 t for round herring and 50 000 t for Lantern and Lightfish (combined). Bycatch species are mainly juvenile sardine, horse mackerel and chub mackerel. It is the largest South African fishery by volume (tons landed) and the second most important in terms of economic value. The wholesale value of catch landed by the sector during 2017 was R2.164 Billion, or 22% of the total value of all fisheries combined.

The total combined catch of anchovy, sardine and round herring landed by the pelagic fishery has decreased by 38% from 395 000 t in 2016 to just 243 000 t in 2021 (Figure 3.17). This is below both long-term (338 000 t) and short-term (294 000 t) averages.

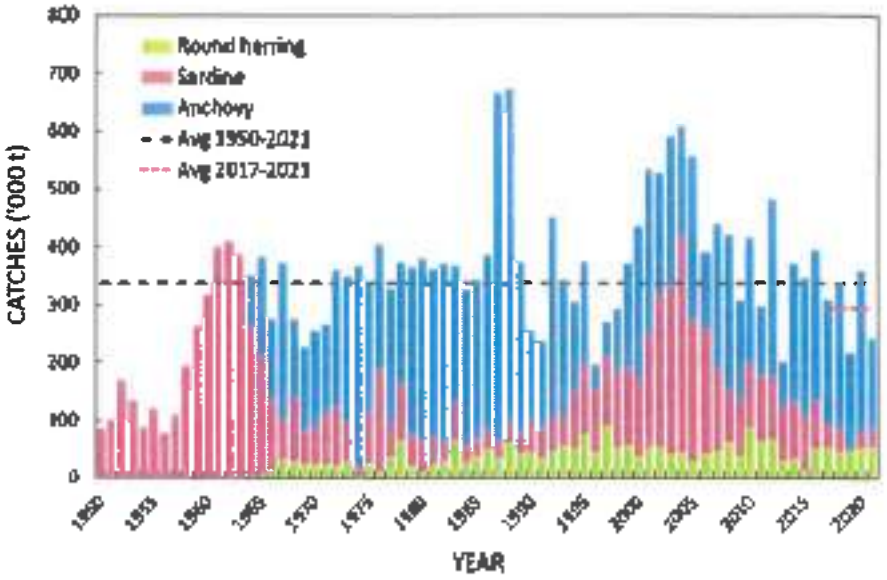

Figure 3.17: The annual combined catch of anchovy, sardine and round herring. Also shown is the average combined catch since the start of the fishery (1950-2021: black dashed line) and for the past five years (red solid line). Source DFFE, 2022.

The abundance and distribution of small pelagic species fluctuates considerably in accordance with the upwelling ecosystem in which they exist. Fish are targeted in inshore waters, primarily along the West and South Coasts of the Western Cape and the Eastern Cape coast, up to a maximum offshore distance of about 100 km.

The fleet consists of approximately 100 wooden, glass-reinforced plastic and steel-hulled vessels ranging in length from 11m to 48 m. The targeted species are surface-shoaling and once a shoal has been located the vessel will steam around it and encircle it with a large net, extending to a depth of 60 m to 90 m (Figure 3.18). Netting walls surround aggregated fish, preventing them from diving downwards. These are surface nets framed by lines: a float line on top and lead line at the bottom. Once the shoal has been encircled the net is pursed, hauled in and the fish pumped on board into the hold of the vessel. It is important to note that after the net is deployed, the vessel has no ability to manoeuvre until the net has been fully recovered on board and this may take up to 1.5 hours. Vessels usually operate overnight and return to offload their catch the following day.

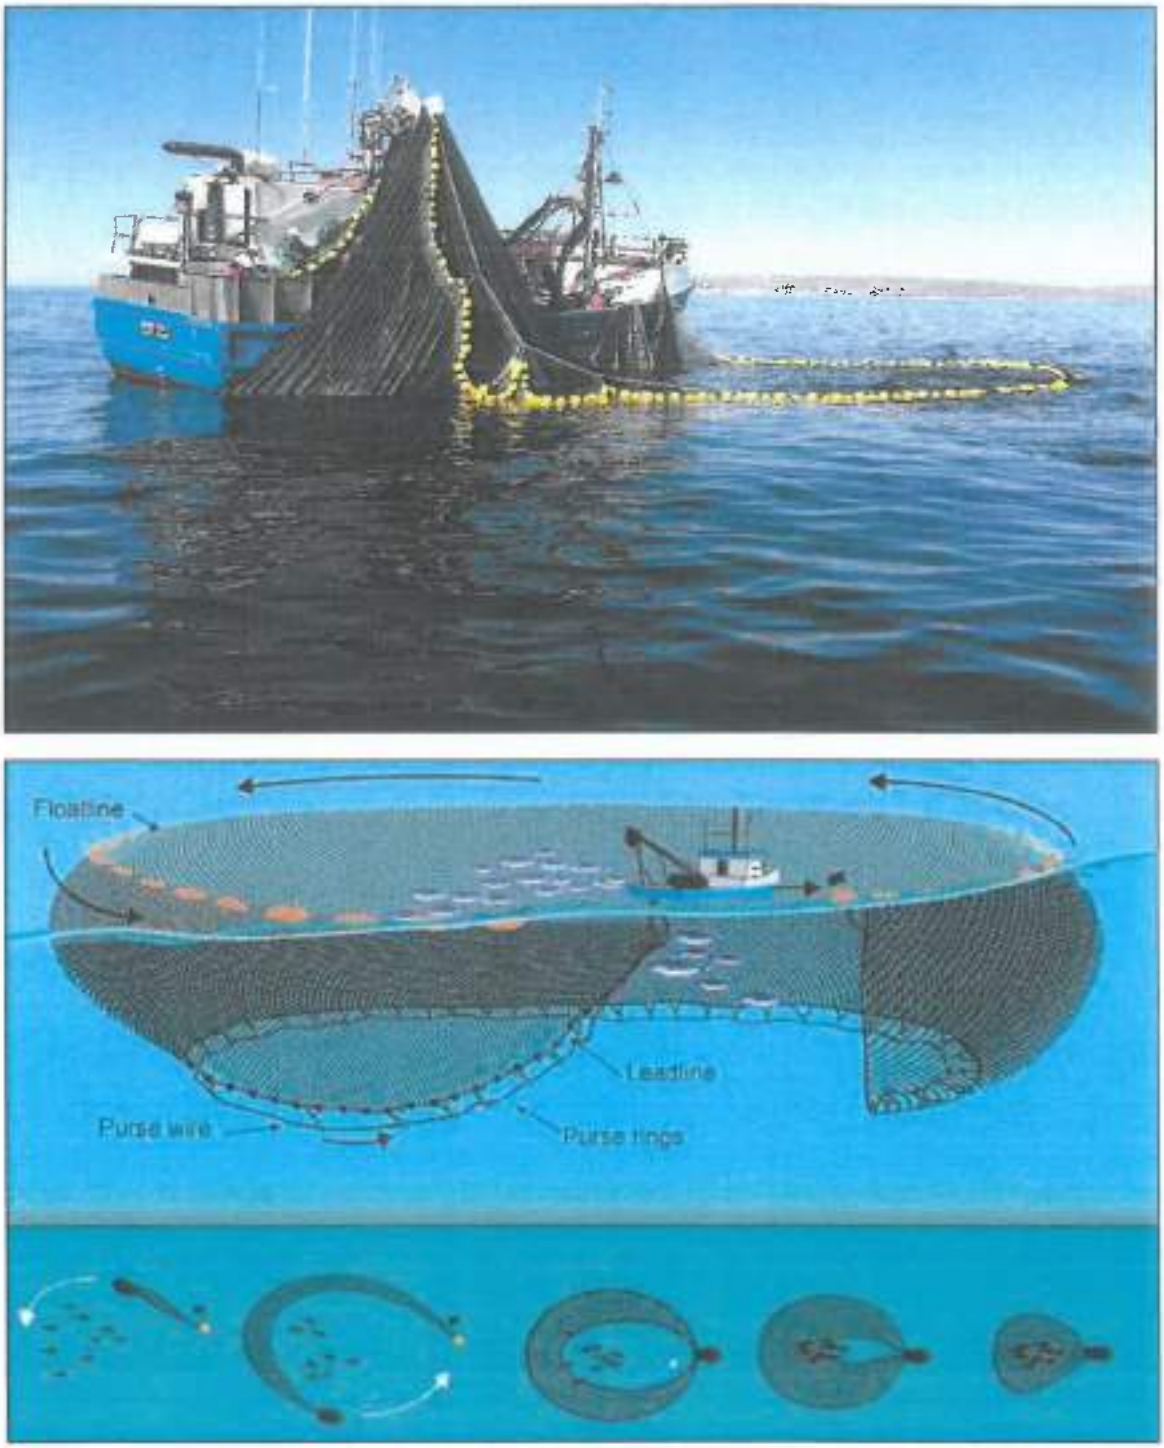

Figure 3.18: (Above) Photograph of a purse-seine vessel registered to fish for small pelagic species. (Below) Typical configuration and deployment of a small pelagic purse seine for targeting anchovy, sardine and round herring as used in South African waters. Source: http://www.afma.gov.au/portfolio-item/purse-seine

The majority of the fleet operate from St Helena Bay, Lasiplek, Saldanha Bay and Hout Bay with fewer vessels operating on the South Coast from the harbours of Gansbaai, Mossel Bay and Port Elizabeth. Ports of deployment correspond to the location of canning factories and fish reduction plants along the coast. The geographical distribution and intensity of the fishery is largely dependent on the seasonal

fluctuation and distribution of the targeted species. The sardine-directed fleet concentrates effort in a broad area extending from Lambert's Bay, southwards past Saldanha and Cape Town towards Cape Point and then eastwards along the coast to Mossel Bay and Port Elizabeth. The anchovy-directed fishery takes place predominantly on the South-West Coast from Lambert's Bay to Kleinbasi (19.5°E) and similarly the intensity of this fishery is dependent on fish availability and is most active in the period from March to September. Round herring (non-quota species) is targeted when available and specifically in the early part of the year (January to March) and is distributed from Lambert's Bay to south of Cape Point. This fishery may extend further offshore than the sardine and anchovy-directed fisheries. The catch and effort statistics for this sector are recorded by skippers on a grid block basis therefore the resolution of 10 by 10 nautical minutes.

The fishery operates throughout the year with a short seasonal break from mid-December to mid-January. Seasonality of catches is shown in Figure 3.19 with an increase in fishing effort and landings evident during the winter months.

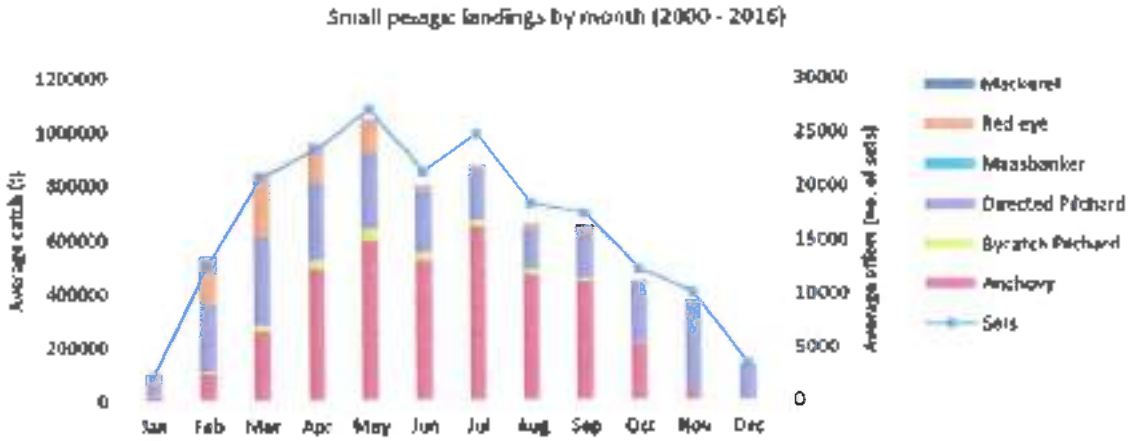

Figure 3.19: Graph showing monthly catch (tons) and effort (number of sets) reported for the small pelagic purse-seine fleet over the period 2000 to 2016 (cumulative).

Figure 3.20 shows the spatial extent of fishing grounds used by the sector over the period 2000 to 2016 in relation to the Reconnaissance Permit application area. The majority of fishing effort takes place in waters shallower than 200 m along the coastline of the Western Cape. Fishing grounds lie at least 60 km inshore of the Reconnaissance Permit application area and there is no overlap.

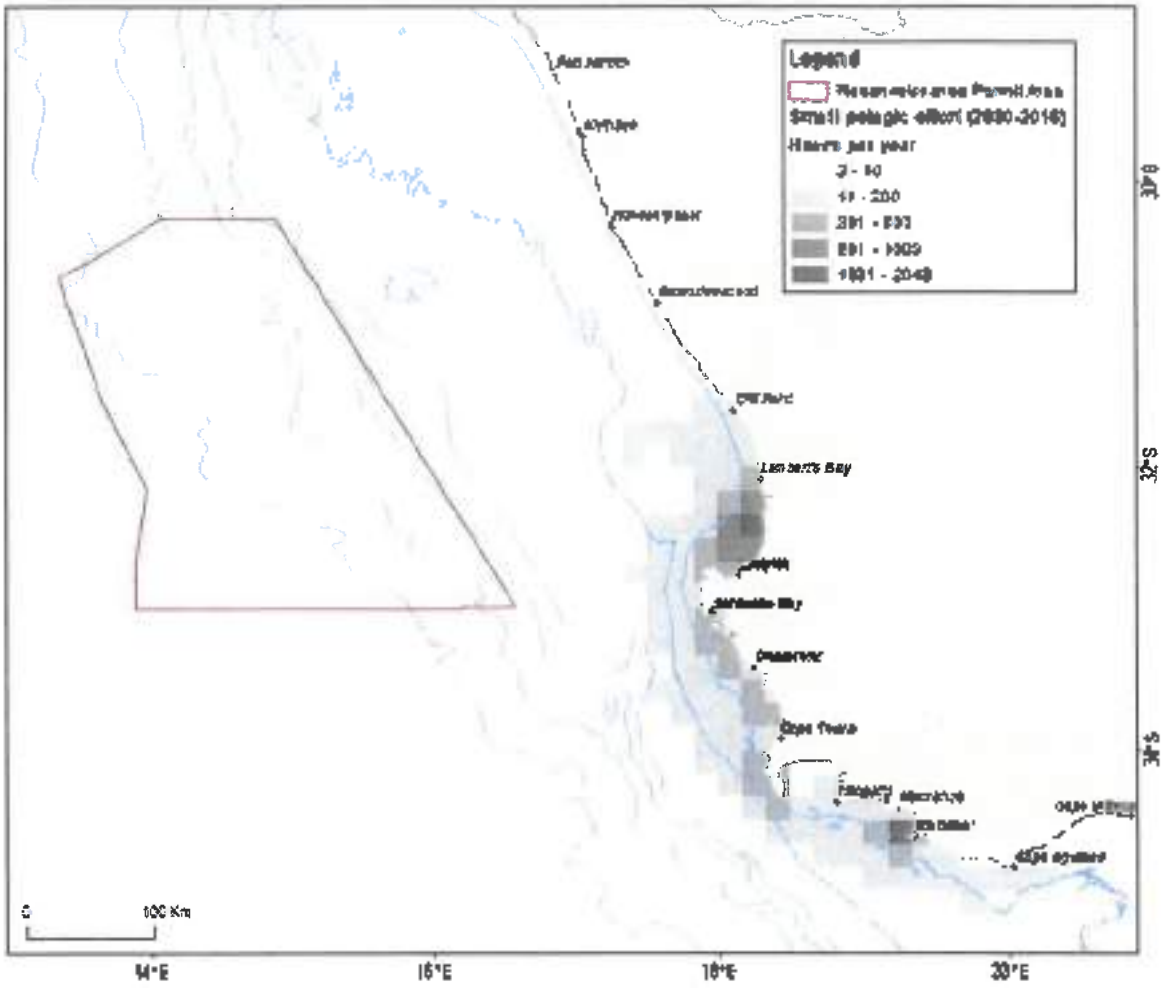

Figure 3.20: An overview of the spatial distribution of fishing effort recorded by the purse-seine sector targeting small pelagic species in in relation to the Reconnaissance Permit application area.

3.3.6 LARGE PELAGIC LONGLINE

Highly migratory tuna and tuna-like species are caught on the high seas and seasonally within the South African Exclusive Economic Zone (EEZ) by the pelagic longline and pole fisheries. Targeted species include albacore (*Thunnus alalunga*), bigeye tuna (*T. obesus*), yellowfin tuna (*T. albacares*) and swordfish (*Xiphias gladius*). The wholesale value of catch landed by the sector during 2017 was R154.2 Million, or 1.6% of the total value of all fisheries combined, with landings of 2541 tons (2017) and 2815 tons (2018). During the period 2000 to 2016, the sector landed an average catch of 4527 tons and set 3.55 million hooks per year. Catch and effort figures reported by the South African large pelagic longline fishery for the years 2000 to 2018 are shown in Figure 3.21. Catch by species and number of active vessels for each year from 2005 to 2018 are given in Table 3.5.

Catches landed by the South African fleet operating in the ICCAT region (i.e. off the West Coast) from 1998 – 2020 are shown in Figure 3.22.

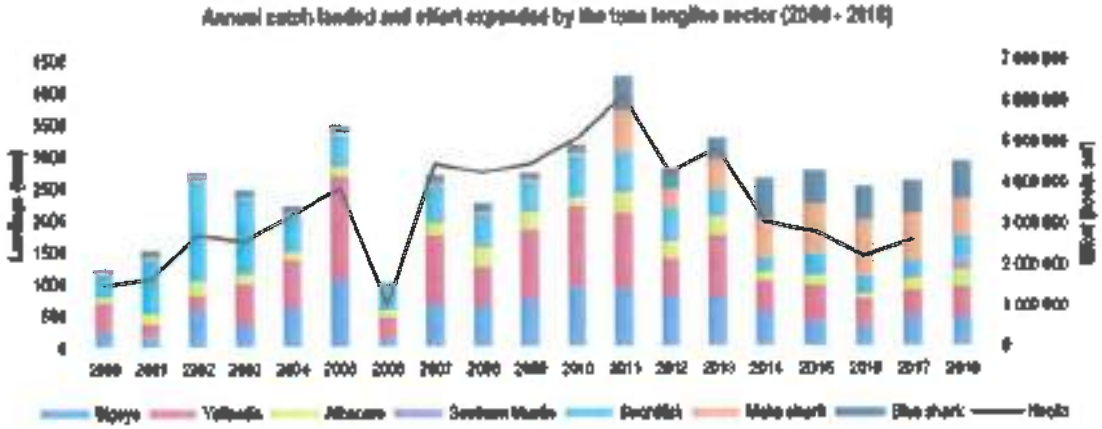

Figure 3.21: Inter-annual variation of catch landed and effort expended by the large pelagic longline sector in South African waters as reported to the two regional management organisations, ICCAT and IOTC (2000 - 2018).

Table 3.6: Total catch (t) and number of active domestic and foreign-flagged vessels targeting large pelagic species for the period 2005-2018 (Source: DEFF, 2019).

Year	Bigeye tuna	Yellowfin tuna	Albacore	Southern bluefin tuna	Swordfish	Shortfin mako shark	Blue shark	Number of active vessels

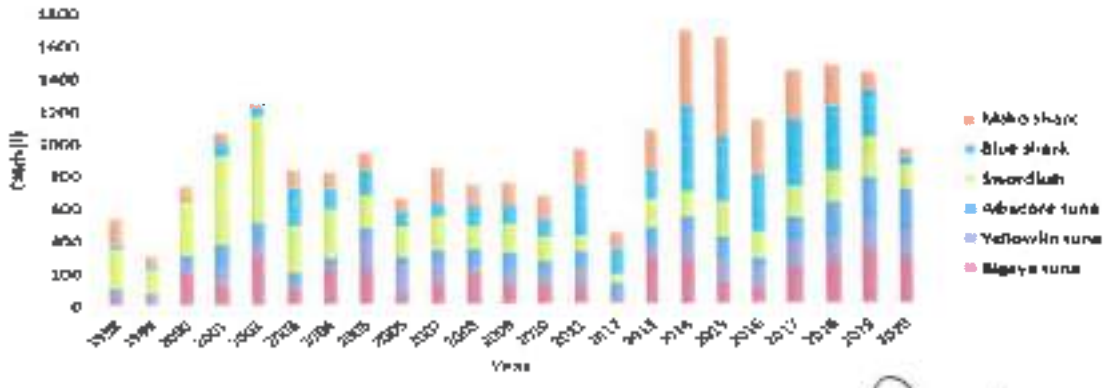

Figure 3.22: Inter-annual variation of catch landed by the large pelagic longline sector operating in the ICCAT region of South African waters (i.e. West of 20°E) (1998 – 2020).

Tuna, tuna-like species and billfishes are migratory stocks and are therefore managed as a "shared resource" amongst various countries under the jurisdiction of the International Commission for the Conservation of Atlantic Tunas (ICCAT) and the Indian Ocean Tuna Commission (IOTC). In the 1970s to mid-1990s the fishery was exclusively operated by Asian fleets (up to 130 vessels) under bilateral agreements with South Africa. From the early 1990s these vessels were banned from South African waters and South Africa went through a period of low fishing activity as fishing rights issues were resolved. Thereafter a domestic fishery developed and 50 fishing rights were allocated to South Africans only. These rights holders now include a fleet of local longliners and several Japanese vessels fishing in joint ventures with South African companies. In 2017, 60 fishing rights were allocated for a period of 15 years. The total number of active longline vessels within South African waters is 22, 18 of which fished in the Atlantic (West of 20°E) during 2017. These were exclusively domestic vessels, with three Japanese vessels fishing exclusively in the Indian Ocean (East of 20°E) during 2017 (DAFF, 2018).

Gear consists of monofilament mainlines of between 25 km and 100 km in length which are suspended from surface buoys and marked at each end. As gear floats close to the water surface it would present a potential obstruction to surface navigation as well as a snagging risk to the gear array towed by the seismic survey vessel. The main fishing line is suspended about 20 m below the water surface via dropper lines connecting it to surface buoys at regular intervals. Up to 3500 baited hooks are attached to the mainline via 20 m long trace lines, targeting fish at a depth of 40 m below the surface. Various types of buoys are used in combinations to keep the mainline near the surface and locate it should the line be cut or break for any reason. Each end of the line is marked by a Dahn Buoy and radar reflector, which marks the line position for later retrieval. Typical configuration of set gear is shown in Figure 3.23 and Figure 3.24.

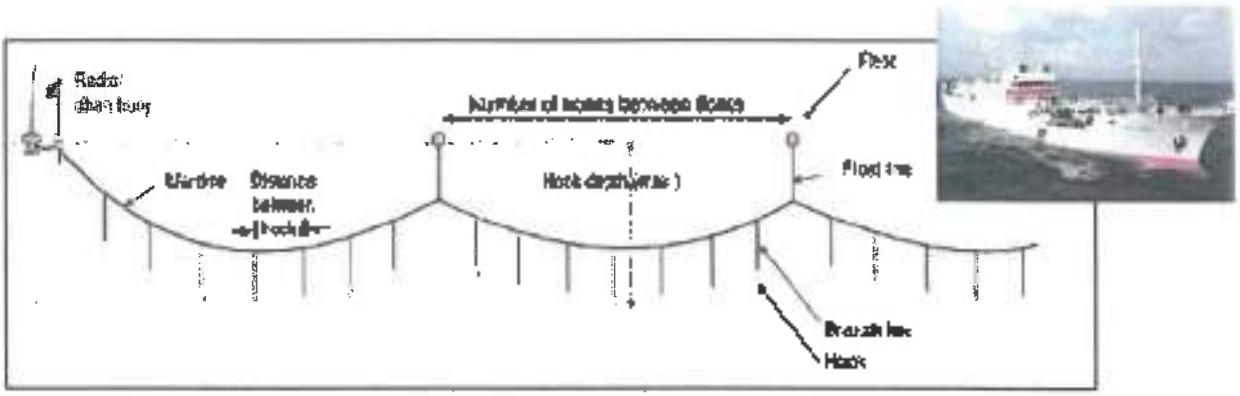

Figure 3.23: Schematic diagram showing typical configuration of longline gear targeting pelagic species (left), and photograph of typical high seas longline vessel (upper right).

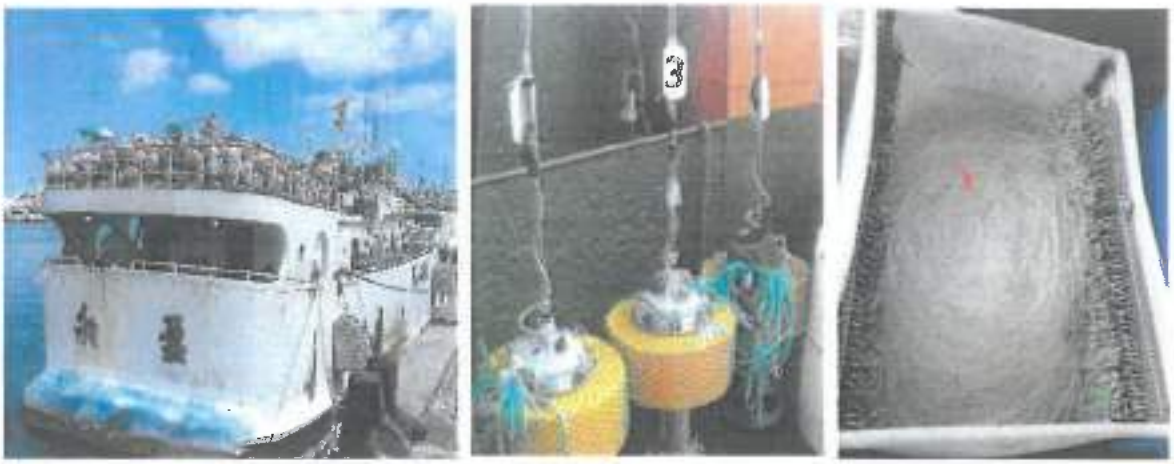

Figure 3.24: Photographs showing marker buoys (left), radio buoys (centre) and monofilament branch lines (right) (Source: CapMarine, 2015).

Lines are usually set at night, and may be left drifting for a considerable length of time before retrieval, which is done by means of a powered hauler at a speed of approximately one knot. During hauling, vessel manoeuvrability is severely restricted. In the event of an emergency, the line may be dropped and hauled in at a later stage.

The fishery operates year-round with a relative increase in effort during winter and spring. Catch per unit effort (CPUE) variations are driven both by the spatial and temporal distribution of the target species and by fishing gear specifications. Variability in environmental factors such as oceanic thermal structure and dissolved oxygen can lead to behavioural changes in the target species, which may in turn influence CPUE (Punsly and Nakano, 1992).

Fishing areas are subdivided into the SE Atlantic (reporting to ICCAT) and the SW Indian Ocean (reporting to IOTC) along 20°E, and the West, Southwest, South and East sampling areas are shown. Bubble size is proportional to the numbers of hooks set per line. CT, Cape Town; PE, Port Elizabeth; EL, East London; DBN, Durban; RB, Richards Bay.

The numbers of hooks set by foreign vessels peaked between May and October each year, whereas local vessels fished throughout the year, with marginally fewer hooks set in January and February than other months (Figure 3.25b). Foreign vessels ventured further southwards than local vessels, which tended to remain within the EEZ (Figure 3.26; Jordaan *et al.*, 2016).

Local vessels fish in all four areas, but in the East their range is limited to the northern half of the area, near a landing site at Richards Bay. Foreign vessels fished mainly in the SW Indian Ocean, with the bulk of all hooks set in the South (58%) and East (33%) areas, and the remaining 9% in the SE Atlantic (Figure 3.25b). Foreign vessels set an average of 2 493 ± 597 (SD) hooks per line, compared to only 1 282 ± 250 hooks per line used by local vessels.

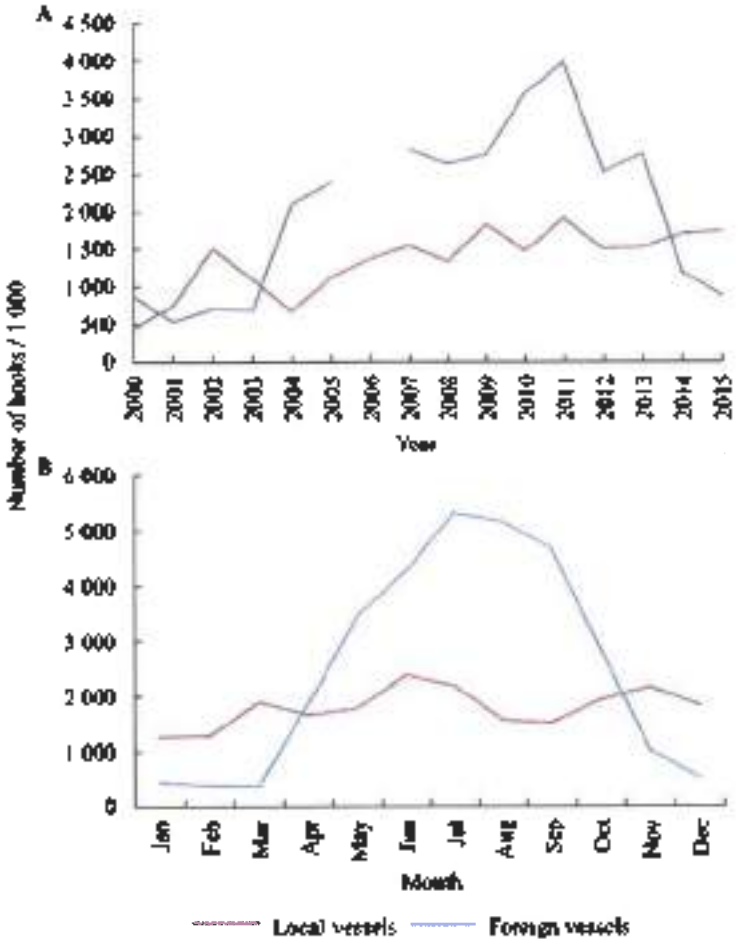

Figure 3.25: Numbers of hooks set per (A) year (2000–2015) and (B) per calendar month, as reported by local and foreign pelagic longliners fishing in the study area (Jordaan et al., 2018).

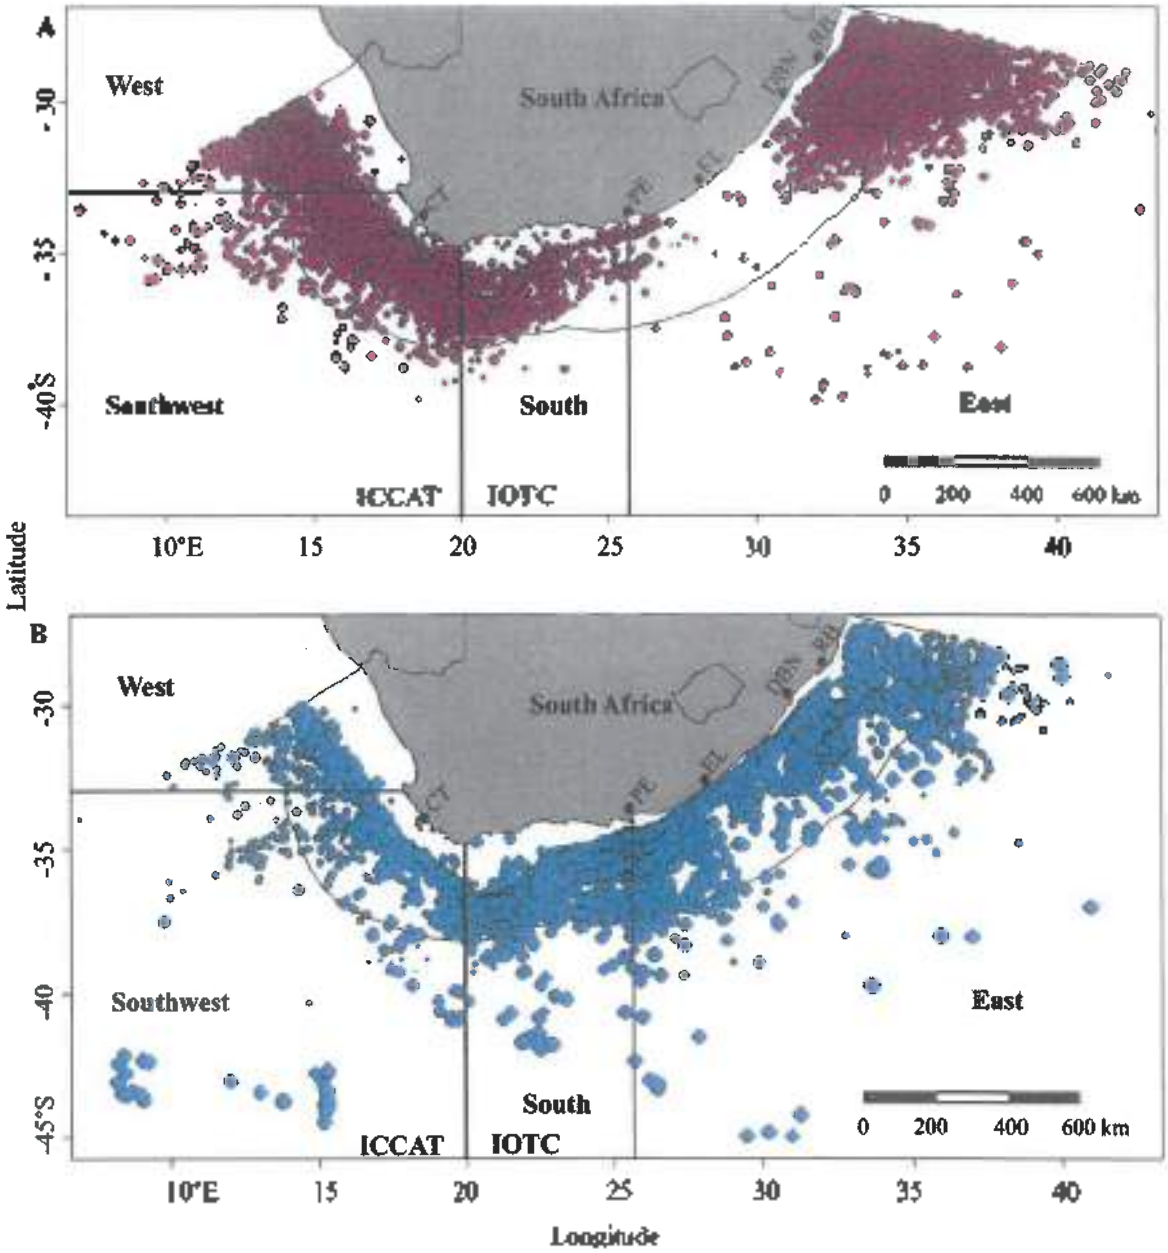

Figure 3.26: Geographical distribution of fishing effort by (A) local and (B) foreign pelagic longliners from 2000 to 2015, based on logbook data provided by vessel skippers (Jordaan *et al.*, 2018).

Rights Holders in the large pelagic longline fishery are required to complete daily logs of catches, specifying catch locations, number of hooks, time of setting and hauling, bait used, number and estimated weight of retained species, and data on bycatch. The fishery operates extensively within the South African EEZ, primarily along the continental shelf break and into deeper waters. The recent spatial distribution of catch (2017 to 2019) in relation to the Reconnaissance Permit area is shown in Figure 3.27. Over this period, an average of 423 lines per year were set within the area yielding 579 tons of catch. This is equivalent to 10.29% of the overall effort and 8.1% of the total catch reported by the sector at a national scale.

Pelagic longline fishing activity can be expected along the inshore extent of the Reconnaissance Permit area especially in the northern extent of the area. Lines of up to 100 km in length are set along the

continental shelf break, and are left to drift in surface currents for several hours before retrieval. They therefore cover a large area whilst they drift and pose a significant risk of entanglement with a towed seismic array.

Average monthly catch and effort within the Reconnaissance Permit area is shown in Figure 3.28. This shows that catch is highest during the months of Jun and July, associated with an increase in fishing effort by the sector.

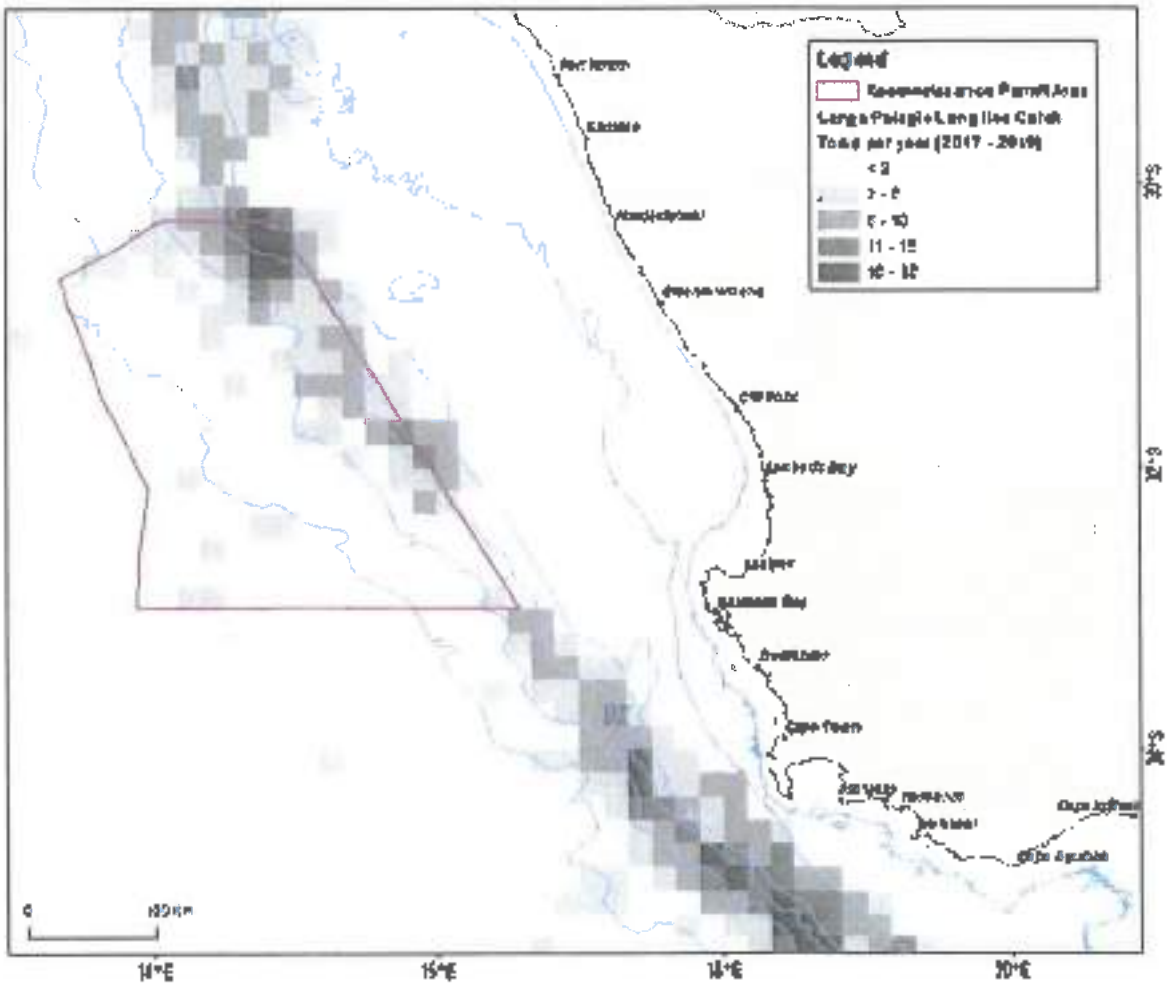

Figure 3.27: An overview of the spatial distribution of fishing effort expended by the longline sector targeting large pelagic fish species in relation to the Reconnaissance Permit application area.

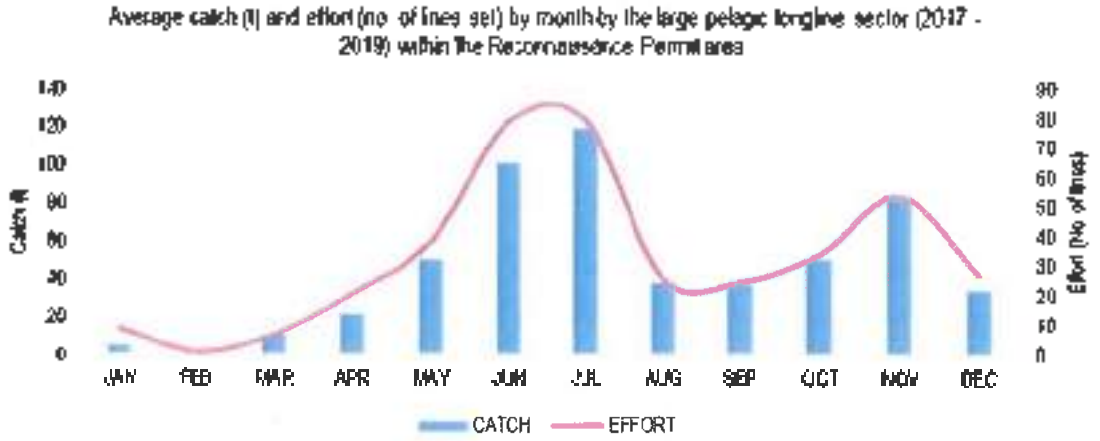

Figure 3.28: Average catch (t) and effort (no. of lines set) by month reported by the large pelagic longline sector in the vicinity of the Reconnaissance Licence area (2017-2019).

3.3.7 TUNA POLE-LINE

Poling for tuna is predominantly based on the southern Atlantic longfin tuna stock also referred to as albacore (*T. alalunga*). Other catch species include yellowfin tuna, bigeye tuna, skipjack tuna (*Katsuwonus pelamis*). The fishery is seasonal with vessels active predominantly between November and June and peak catches recorded from November to January. Due to the seasonality of tuna in South Africa's waters the tuna pole fishery is also allowed access to snoek (*Thyrsites atun*) and yellowtail (*Seriola lalandi*). Snoek-directed fishing activity is seasonal, taking place in coastal areas during the period March to July, with a peak in activity during the months of April and May. Access to these additional species has caused conflict with the traditional linefish sector.

The reported wholesale value of the fishery in 2018 was R124 Million in 2018, or 1.2% of the total value of all fisheries combined. In 2020, landings of albacore amounted to 3941 tons. A historical time series of catch and effort reported by the South African sector operating within the Atlantic region is shown in Table 3.6. The total effort of 4131 catch days within the ICCAT convention area in 2019 represents an increase in effort of 9% compared to 2018. The total reported annual pole fleet catch of the main target species albacore and yellowfin tuna showed for the first time relative increases since 2015 and 2014, respectively.

Table 3.7: Total number of fishing days (effort), active vessels and total catch (t) of the main species caught by South African-flagged tuna pole-line vessels in the ICCAT region (West of 20E), 2008 – 2020 (ICCAT, 2022).

	Total Effort		Catch (t)			
Year	Fishing days	Active vessels	Albacore	Yellowfin tuna	Bigeye tuna	Skipjack tuna
2008	3052	115	2083	347	8	4
2009	4431	123	4586	223	17	4
2010	4408	116	4087	177	8	1
2011	5001	118	3166	629	15	5
2012	5157	123	3483	162	12	8
2013	4114	107	3492	374	142	3
2014	4416	95	3620	1351	50	5
2015	4738	91	3898	885	57	2

2016	4908	98	2001	599	10	2
2017	3062	92	1640	235	22	7
2018	3751	92	2353	242	14	2
2019	4131	93	2190	378	91	2
2020	3975	97	3941	534	71	1

The active fleet consists of approximately 92 pole-and-line vessels (also referred to as "baitboat"), which are based at the ports of Cape Town, Hout Bay and Saldanha Bay. Vessels normally operate within a 100 nm radius of these locations with effort concentrated in the Cape Canyon area (South-West of Cape Point), and up the West Coast to the Namibian border with South Africa.

Vessels are typically small (an average length of 16 m but ranging up to 25 m). Catch is stored on ice, refrigerated sea water or frozen at sea and the storage method often determines the range of the vessel. Trip durations average between four and five days, depending on catch rates and the distance of the fishing grounds from port. Vessels drift whilst attracting and catching shoals of pelagic tunas. Sonars and echo sounders are used to locate schools of tuna. Once a school is located, water is sprayed outwards from high-pressure nozzles to simulate small baitfish aggregating near the water surface. Live bait is then used to entice the tuna to the surface (chumming). Tuna swimming near the surface are caught with hand-held fishing poles. The ends of the poles are fitted with a short length of fishing line leading to a hook. In order to land heavier fish, lines may be strung from the ends of the poles to overhead blocks to increase lifting power (see Figure 3.30).

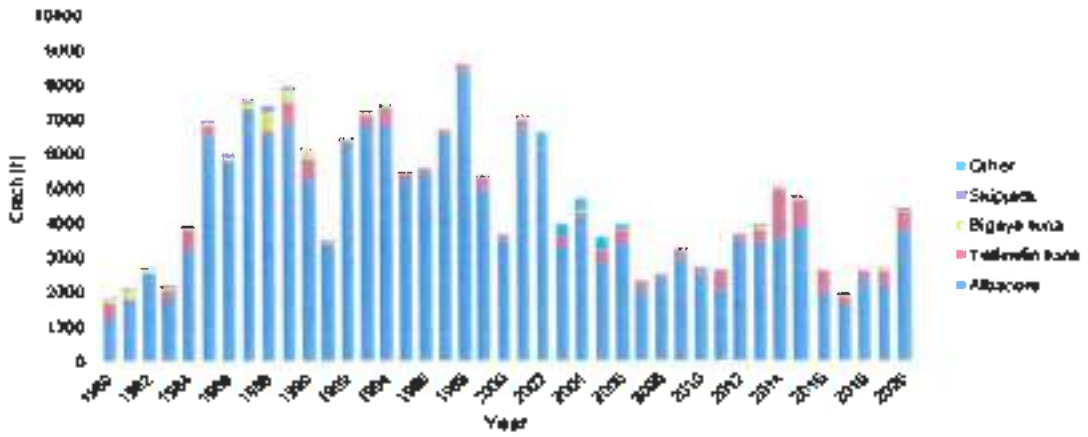

Figure 3.29: Catches (tons) of pelagic species by the South Africa pole-line ("Baitboat") fleet between 1980 and 2020 (ICCAT, 2022).

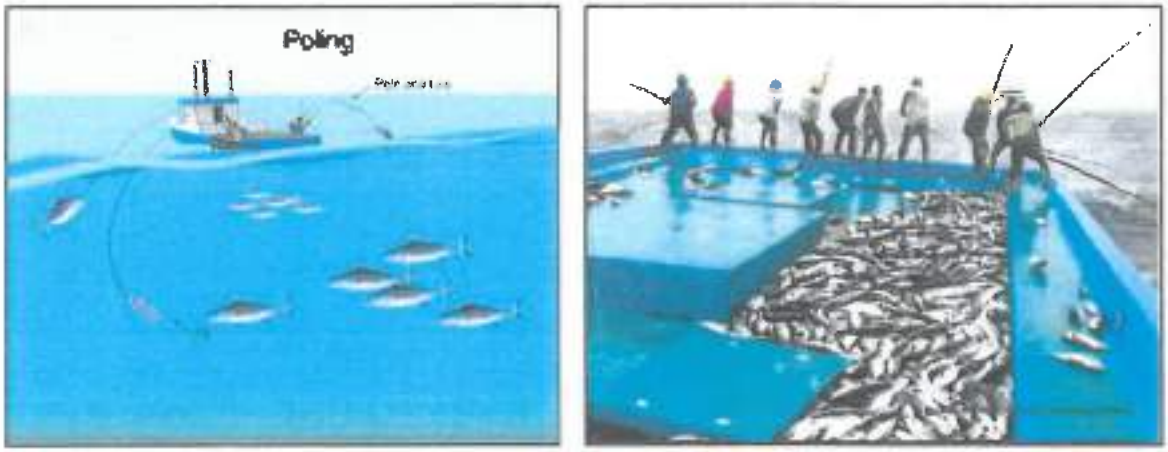

Figure 3.30: Schematic diagram of pole and line operation (Source: http://www.afma.gov.au/portfolio-item/minor-lines).

The nature of the fishery and communication between vessels often results in a large number of vessels operating in close proximity to each other at a time. The vessels fish predominantly during daylight hours and are highly manoeuvrable. However, at night in fair weather conditions the fleet of vessels may drift or deploy drogues to remain within an area and would be less responsive during these periods.

Figure 3.31 shows the location of fishing activity in relation to Reconnaissance Permit application area. Fishing activity for tuna occurs along the entire West Coast beyond the 200 m bathymetric contour, along the shelf break with favoured fishing grounds including areas north of Cape Columbine and between 60 km and 120 km offshore of Saldanha Bay. Fishing records received from DFFE for the reporting period 2017 to 2019 show that tuna-directed fishing takes place inshore of the Reconnaissance Permit application area within minimal activity within the area itself. An average of 24 fishing events per year were set within the area yielding 25 tons of albacore (although it is likely that some of this activity may be errors in the reporting of fishing positions and the likelihood of fishing activity within the area is considered to be low). The catch and effort within the area is equivalent to 0.87% and 0.95%, respectively, of the overall catch and effort reported by the sector at a national scale.

Albacore-directed fishing activity within deeper waters adjacent to the Reconnaissance Permit area shows a peak during February and March (see Figure 3.32). Snoek-directed fishing activity is coastal and seasonal in nature – taking place inshore of the 100 m depth contour during the period March to July, with a peak in activity during the months of April and May. Snoek-directed fishing activity is situated at least 140 km inshore of the application area and there is therefore no overlap of the survey expected with snoek-directed fishing activity.

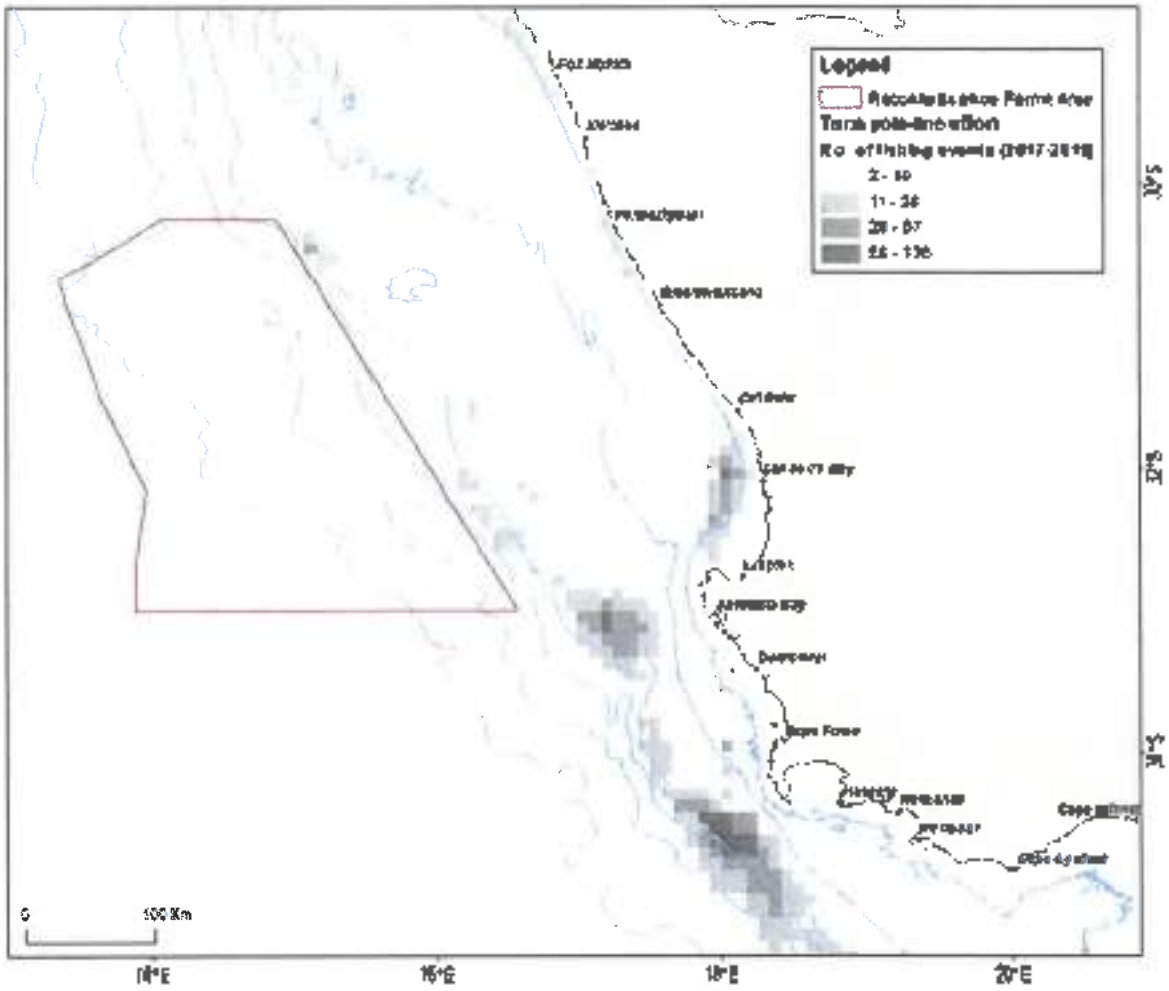

Figure 3.31: An overview of the spatial distribution of fishing effort expended by the pole- line sector targeting pelagic tuna (offshore areas) and snoek (inshore areas) in relation to the Reconnaissance Permit application area.

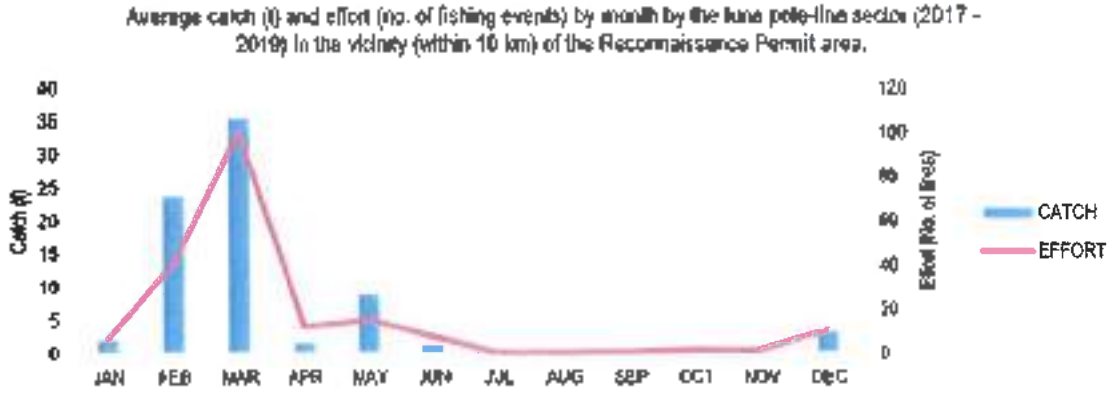

Figure 3.32: Average catch (t) and effort (no. of fishing events) by month reported by the tuna pole-line sector in the vicinity (within 10 km) of the Reconnaissance Licence area (2017-2019).

3.3.8 TRADITIONAL LINEFISH

The commercial linefish sector has its origins from the recreational sector. Essentially recreational linefishers commercialised resulting in a systematic decline in the "linefish" stocks. The Minister of Fisheries in the 1980's reformed the sector. This was done by creating a small commercial linefish sector, as well as introducing a moratorium on exploiting many species that were collapsed or near collapse. The commercial linefish sector now only allows a limited number of key species to be exploited.

Of all South African marine fisheries, the linefishery is the most vulnerable to external impacts. Linefish recources are at risk of overcapacity as they area directly or indirectly exploited by other sectors, including the recreational, small-scale linefishery, inshore and offshore trawl fisheries, tuna pole-line fishery, the inshore netfishery and the demersal shark longline fishery (DEFF, 2020). The increased expectation of commercial access to linefish resources combined with the localised anticipation of community ownership by small-scale fishers may impact linefish stocks.

The traditional linefishery is the country's third most important fishery in terms of tonnage landed and economic value. It is a long-standing, nearshore fishery based on a large assemblage of different species using hook and line, but excludes the use of longlines. Within the Western Cape the predominant catch species is snoek (*Thyrsites atun*) while other species such as Cape bream (hottentot) (*Pachymetopon blochii*), geelbek (*Atractoscion aequidens*), kob (*Argyrosomus japonicus*) and yellowtail (*Seriola lalandi*) are also important. Towards the East Coast the number of catch species increases and includes resident reef fish (Sparidae and Serranidae), pelagic migrants (Carangidae and Scombridae) and demersal migrants (Sciaenidae and Sparidae). Table 3.7 lists the catch of important linefish species for the years 2010 to 2022.

Figure 3.33 shows the variability in catches of the eight most importance species by the linefishery over the period 1985 to 2021.

Table 3.7: Annual catch (t) of the eight most important linefish species for the period 2010 to 2021 (DEFF, 2022).

Year	Snoek	Yellowtail	Kob	Carpenter	Slinger	Hottentot seabream	Geelbek	Santer	Total catch

*total catches unavailable at date of this report

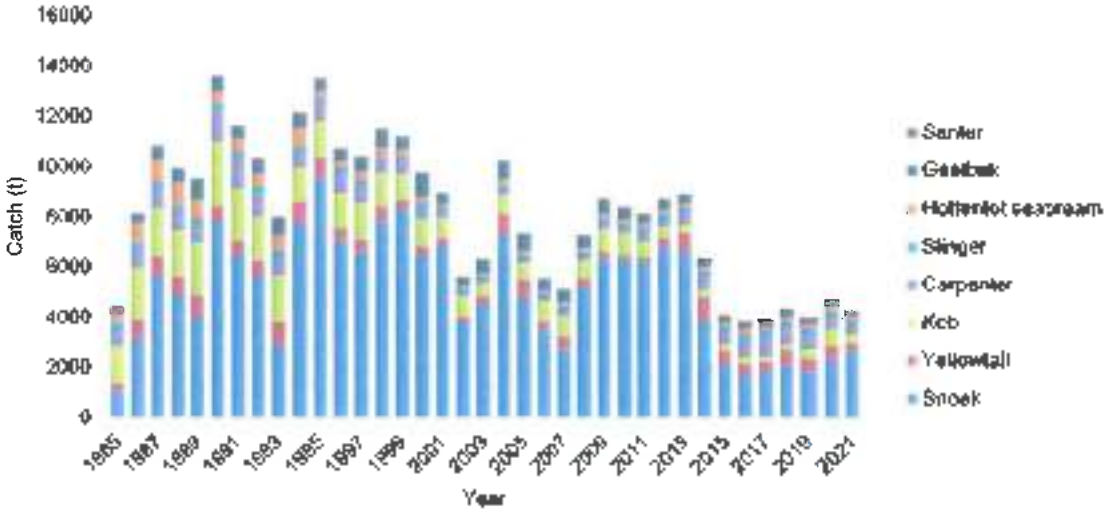

Figure 3.33: Annual catch (t) of the eight most important linefish species for the period 1985-2021 (DFFE, 2022).

The traditional commercial line fishery is a relatively low-cost and labour-intensive industry, therefore important from an employment and human livelihood point of view. Although the commercial linefishery has the largest fleet, it contributes only 6% of the total estimated value of all South African marine fisheries (DFFE, 2020). In 2017, the wholesale value of catch was reported as R122.1 million.

The commercial line fishery is a nearshore boat-based activity which is currently managed through a total allowable effort (TAE) allocation, based on boat and crew numbers. Since December 2000 it has consisted of 3450 crew operating from 455 commercial vessels. The number of rights holders is 425 (valid rights until 31 December 2020 and subsequently extended until 31 December 2021[2]). For the 2019/2020 fishing season, 395 vessels and 3007 crew was apportioned to commercial fishing, whilst 60 vessels and 443 crew was apportioned to small-scale fishing (refer to Section 3.3.10). DFFE proposed an increase in the apportionment of TAE to small-scale fishing from 13% to 50% commencing in 2021 in order to boost economic possibilities for coastal communities.

Annual catches prior to the reduction of the commercial effort were estimated at 16 000 tons for the traditional commercial line fishery. Almost all of the traditional line fish catch is consumed locally. The fishery is widespread along the country's shoreline from Port Nolloth on the West Coast to Cape Vidal on the East Coast. Effort is managed geographically with the spatial effort of the fishery divided into three zones. Zone A extends from Port Nolloth to Cape Infanta, Zone B extends from Cape Infanta to Port St Johns and Zone C covers the KwaZulu-Natal region.

Table 3.8 lists the annual Total Allowable Effort (TAE) and activated effort per line fish management zone from 2007 to 2019. Most of the catch (up to 95%) is landed by the Cape commercial fishery, which operates on the continental shelf from the Namibian border on the West Coast to the Kei River in the Eastern Cape.

[2] Extension to existing rights until DFFE has concluded a Fishing Rights Allocations Process ('FRAP') which, at the time of this report, is still underway.

Table 3.8: Annual total allowable effort (TAE) and activated commercial line fish effort per management zone from 2008 to 2019 (DEFF, 2020).

Total TAE boats (fishers). Upper limit: 455 boats or 3450 crew			Zone A: Port Nolloth to Cape Infanta		Zone B: Cape Infanta to Port St Johns		Zone C: KwaZulu-Natal

** In the finalisation of the 2013 commercial Traditional Linefish appeals, the effort apportioned for the small-scale fisheries sector was allocated to the commercial sector. All the small-scale rights were considered to be activated on allocation

Crew use hand line or rod-and-reel to target approximately 200 species of marine fish along the full 3 000 km coastline, of which 50 species may be regarded as economically important. To distinguish between line fishing and long lining, line fishers are restricted to a maximum of 10 hooks per line. Target species include resident reef-fish, coastal migrants and nomadic species. Many species allocated to the small-scale fisheries "baskets" are primary targets of the commercial and recreational linefish sectors, and these shared resources must be carefully monitored given the increased fishing pressure expected. A revision of the linefish management protocol (LMP) is also underway to ensure the future sustainability of linefish stocks.

Vessels range in length between 4.5 m and 11 m and the offshore operational range is restricted by vessel category to 40 nautical miles (75 km). Fishing effort at this outer limit is sporadic. Operating ranges vary greatly but most of the activity is conducted within 15 km of a launch site. Fishing takes place throughout the year but there is some seasonality in catches.

Snoek is an important linefish species as it makes up the largest annual catch in terms of biomass, contributing more than 80% to the total catch west of Cape Infanta. Snoek spawning occurs offshore during winter-spring, along the shelf break (150-400 m) of the western Agulhas Bank and the South African west coast. Prevailing currents transport eggs and larvae to a primary nursery ground north of Cape Columbine and to a secondary nursery area to the east of Danger Point; both shallower than 150 m. Juveniles remain on the nursery grounds until maturity, growing to between 33 and 44 cm in the first year (3.25 cm/month). Onshore-offshore distribution (between 5- and 150-m isobaths) of juveniles is determined largely by prey availability and includes a seasonal inshore migration in autumn in response to clupeoid recruitment. Adults are found throughout the distribution range of the species, and although they move offshore to spawn - there is some southward dispersion as the spawning season progresses - longshore movement is apparently random and without a seasonal basis (Griffiths, 2002). Snoek are caught within the inshore zone along most of the South African coastline with the majority of catches being made along the West and South-West Coast of South Africa. Although snoek can be caught year-round, during the snoek seasonal migration (between April and July) when they shoal nearshore, they are caught more frequently using handlines by the linefishery. Snoek are not distributed offshore of the 1000 m depth contour and therefore not targeted or caught by the commercial linefishery in the Reconnaissance Permit area.

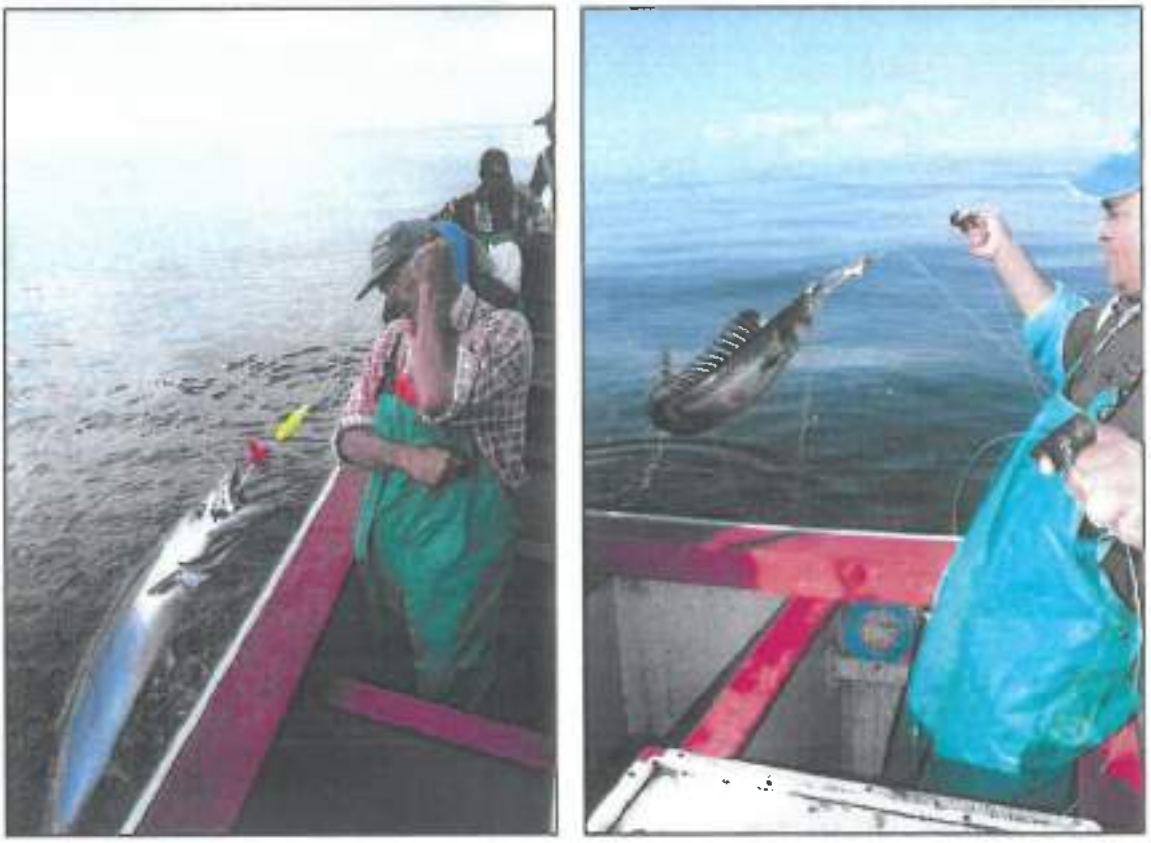

Figure 3.34: Fishermen landing snoek on board a vessel operating in the traditional linefishery (photo credit Jaco Barendse).

Spatial mapping of effort and catches in the line fishery is less accurate than in other sectors because of the reporting structure implemented by DFFE. Fishing locations are described by skippers in relation to numbered sections along the coast and estimated distance offshore. No bearings are given, and no GPS data are recorded. Furthermore, due to the large number of vessels, associated reporting complexities and also the unwillingness of local fisherman to share fishing locations, inaccuracies in the spatial representation are to be expected[3]. This fishery's operational footprint may at times be limited by operating costs and is sensitive to local reports of fish availability. Further, in regard to migratory species, such as longfin tuna and snoek, economic and regulatory aspects relating to distances fished offshore is pertinent (i.e. such as the requirements of the South African Maritime Safety Authority (SAMSA)) in particular that "B" class certified vessels can operate up to 40 nm offshore.

Figure 3.35 shows the spatial extent of traditional linefish grounds in relation to the Reconnaissance Permit application area. Snoek-directed fishing effort is coastal, with vessels operating in waters shallower than 100 m. However, there are records of fishing up to an offshore distance of 55 km off Saldanha Bay where tuna are targeted in the vicinity of Cape Canyon. Note that small-scale fishers are not permitted to target tuna (i.e. the species is not part of the basket allocation), thus would not be

[3] Inaccuracies in reported fishing positions are unlikely to impact on the validity of the current assessment as a precautionary approach has already been adopted in assessing the maximum range of fishing grounds offshore with respect to the Reconnaissance Permit application area.

expected to operate at the Cape Canyon. There is no overlap of fishing grounds with the Reconnaissance Permit application area, which is situated at least 120 km offshore and at least 100 km from fishing grounds targeted by the linefish sector.

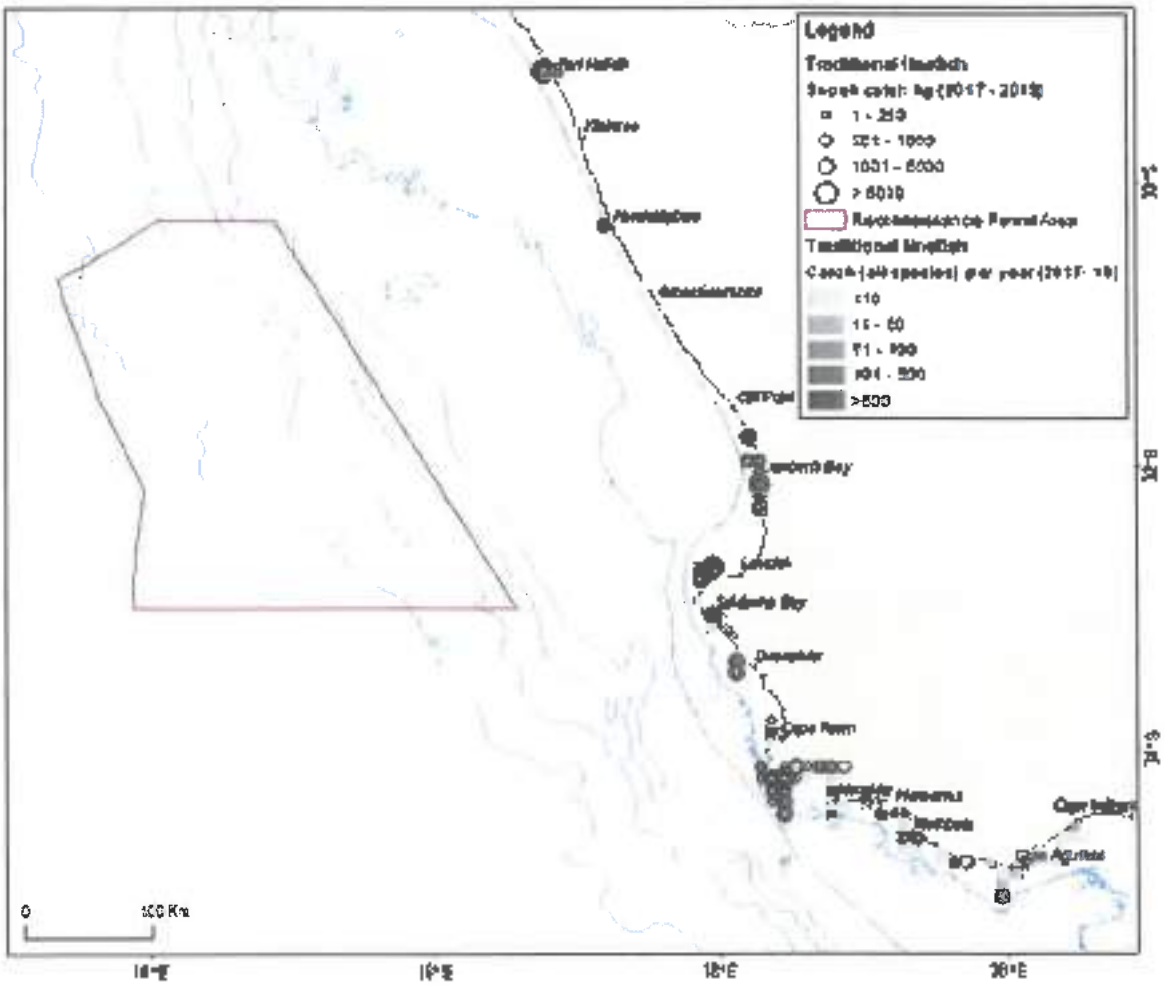

Figure 3.35: An overview of the spatial distribution of catch taken by the linefish sector in relation to the Reconnaissance Permit application area. The snoek component of catch is shown as well as total catch of all species.

3.3.9 WEST COAST ROCK LOBSTER

The West Coast rock lobster (*Jasus lalandii*) is a valuable resource found off the South African West Coast and consequently an important income source for West Coast fishermen providing employment for about 4200 people. The resource occurs inside the 200 m depth contour along the West Coast from Namibia to East London on the East Coast of South Africa. Fishing grounds stretch from the Orange River mouth to east of Cape Hangklip in the South-Eastern Cape although the commercial viability is focused mainly southwards from Management Zone B (see Figure 3.38).

The fishery is comprised of four sub-sectors – commercial offshore, commercial nearshore, small-scale and recreational, all of which have to share from the same national TAC. The 2021/22 TAC was set at 600 tonnes and apportionment of TAC by sub-sector is listed in Table 3.9. The TAC for the 2021/2022 fishing season was reduced by 29% from the previous fishing season (2020/2021). The updated stock assessment for the resource has indicated that it is further depleted than was thought to be the case

two years ago, and poaching[4] is one of the major contributors to the recently exacerbated depleted status of the resource. The resource has over recent decades been at about 2.5% of the pristine level, but that over the last few years this had dropped to about 1.5%.

Annual TAC and average monthly landings over the period 2006 to 2020 are shown in Figures 3.36 and Figure 3.37, respectively. A historical time-series of TACs and landings is listed in Table 3.10.

Table 3.9: Apportionment of TAC of rock lobster by sub-sector (modified DFFE, 2021).

Description	2019/2020 TAC (t)	2020/2021 TAC (t)	2021/2022 (t)

[1] No Interim Relief allocated
[2] Interim Relief accommodated under Recreational allocation

[4] In 2017, the poached rock lobster was estimated at 2 747 tonnes.

* Total catch by all sectors

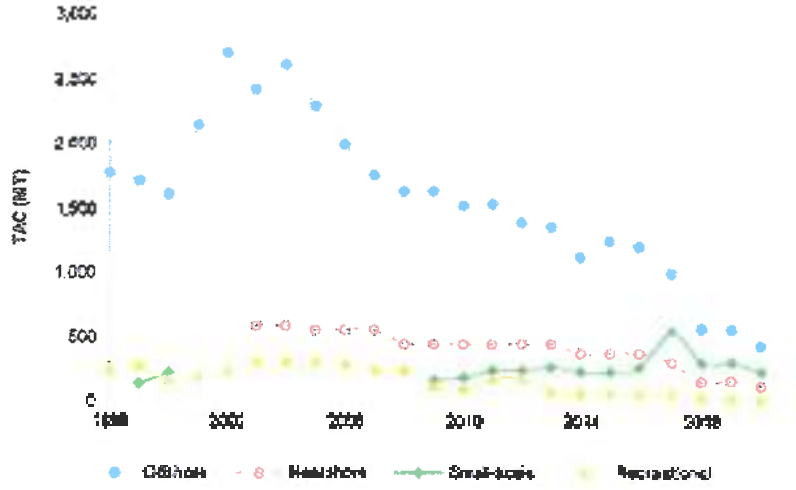

Figure 3.36: Graph showing the total allowable catch (TAC) of west coast rock lobster.

Figure 3.37: Graph showing the average monthly catch (tonnes) and effort (number of traps hauled) reported by the offshore (trapboat) and inshore (bakkie) rock lobster sectors over the period 2006 to 2020.

The resource is managed geographically, with TACs set annually for different management areas. The commercial and small-scale fishing sectors are authorised to undertake fishing for four months in each management zone therefore closed seasons are applicable to different management zones. The start and end dates for the 2021/22 fishing season per sector and zone are shown in Table 3.11.

Table 3.11: Start and end dates for the fishing season 2021/22 by management zone. Special Project Report on the review of the TAC for West Coast Rock Lobster for the 2021/22 fishing season by the Consultative Advisory Forum for Marine Living Resources.

Area	Catch period	
	Commercial nearshore, interim relief, small-scale: nearshore	Commercial offshore, small-scale: offshore
Area 1 + 2	15 Oct, Nov, Dec, Jan, 15 Feb	
Area 3 + 4	15 Nov, Dec, Jan, Feb, 15 Mar	15 Nov, Dec, Jan, Feb, 15 Mar
Area 5 + 6	15 Nov, Dec, Jan, Feb, 15 Mar	
Area 7		Dec, Jan, Feb, Mar

Areas 8 and 11	15 Nov, Dec, Jan, Feb, 15 Mar	Jan, Mar, Apr, May
Area 8 (deep water)		Jun, Jul
Areas 12, 13 and 14	15 Nov, Dec, Jan, Feb, 15 Mar	

The commercial offshore sector operates at a depth range of approximately 30 m to 100 m, making use of traps consisting of rectangular metal frames covered by netting. These traps are set at dusk and retrieved during the early morning. Approximately 138 vessels participate in the offshore sector.

The commercial nearshore sector makes use of hoop nets to target lobster at discrete suitable reef areas along the shore at a water depth of up to 15 - 30 m. These are deployed from a fleet of small dinghies/bakkies which operate from the shore and coastal harbours. Approximately 653 boats participate in the sector.

The delineation of management zones is shown in Figure 3.38. The five super-areas are: areas 1-2, corresponding to zone A; areas 3-4, to zone B; areas 5-6, to zone C; area 7, being the northernmost area within zone D; and area 8+, comprising area 8 of zone D as well as zones E and F.

Figure 3.39 shows rock lobster catch by management zone for the commercial offshore and nearshore sub-sectors. The Reconnaissance Permit area is situated at least 115 km from the closest rock lobster fishing grounds and there is no spatial overlap (see Figure 3.40).

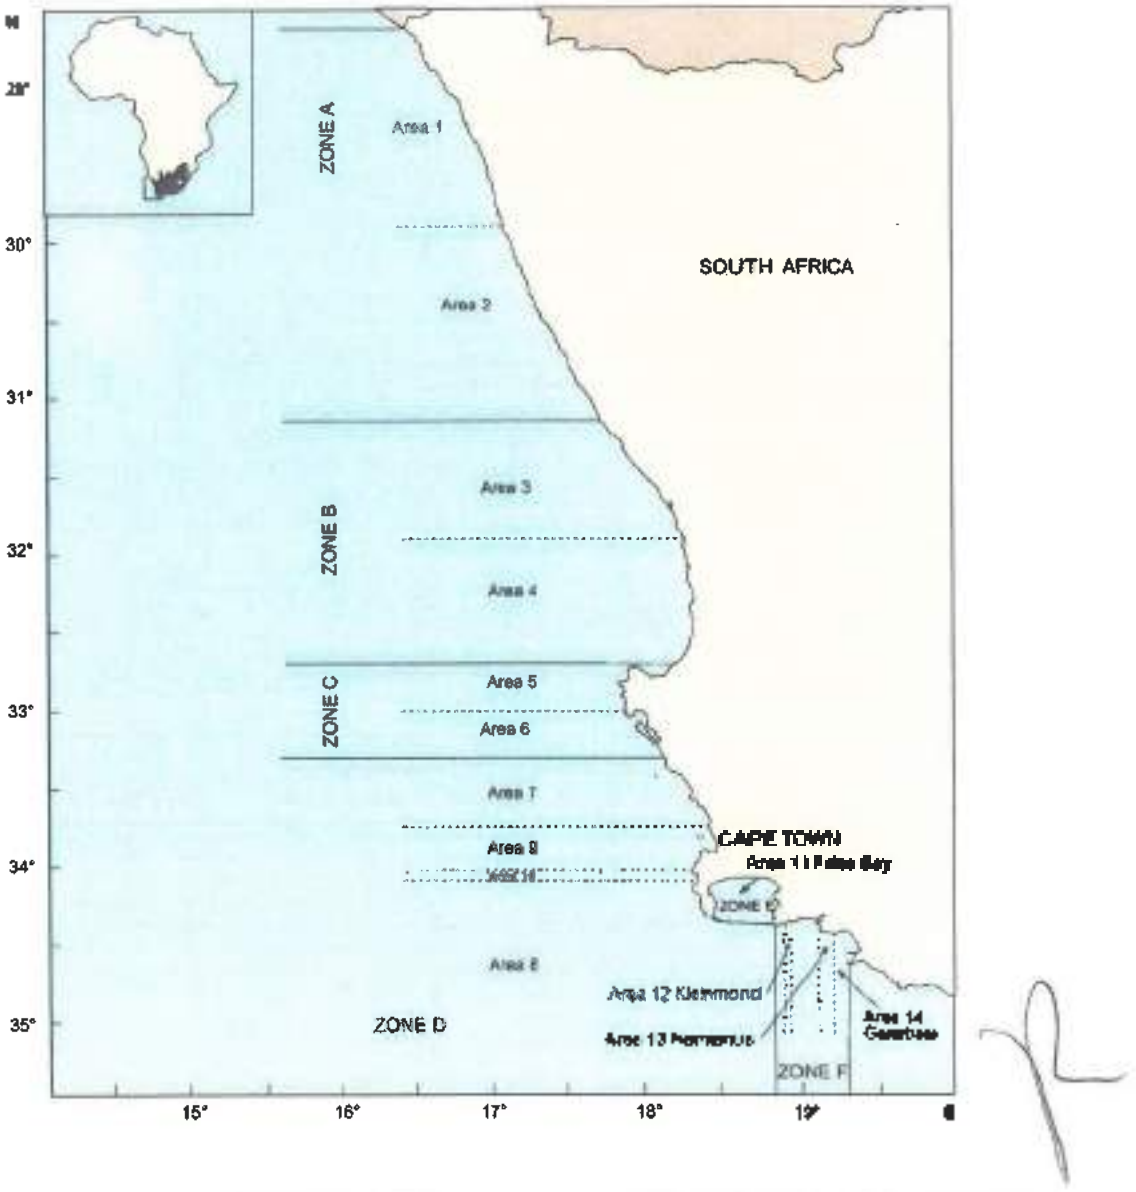

Figure 3.36: West Coast rock lobster fishing zones and areas. The five super-areas are: areas1–2, corresponding to zone A; areas 3–4, to zone B; areas 5–6, to zone C; area 7, being the northernmost area within zone D; and area 8+, comprising area 8 of zone D as well as zones E and F.

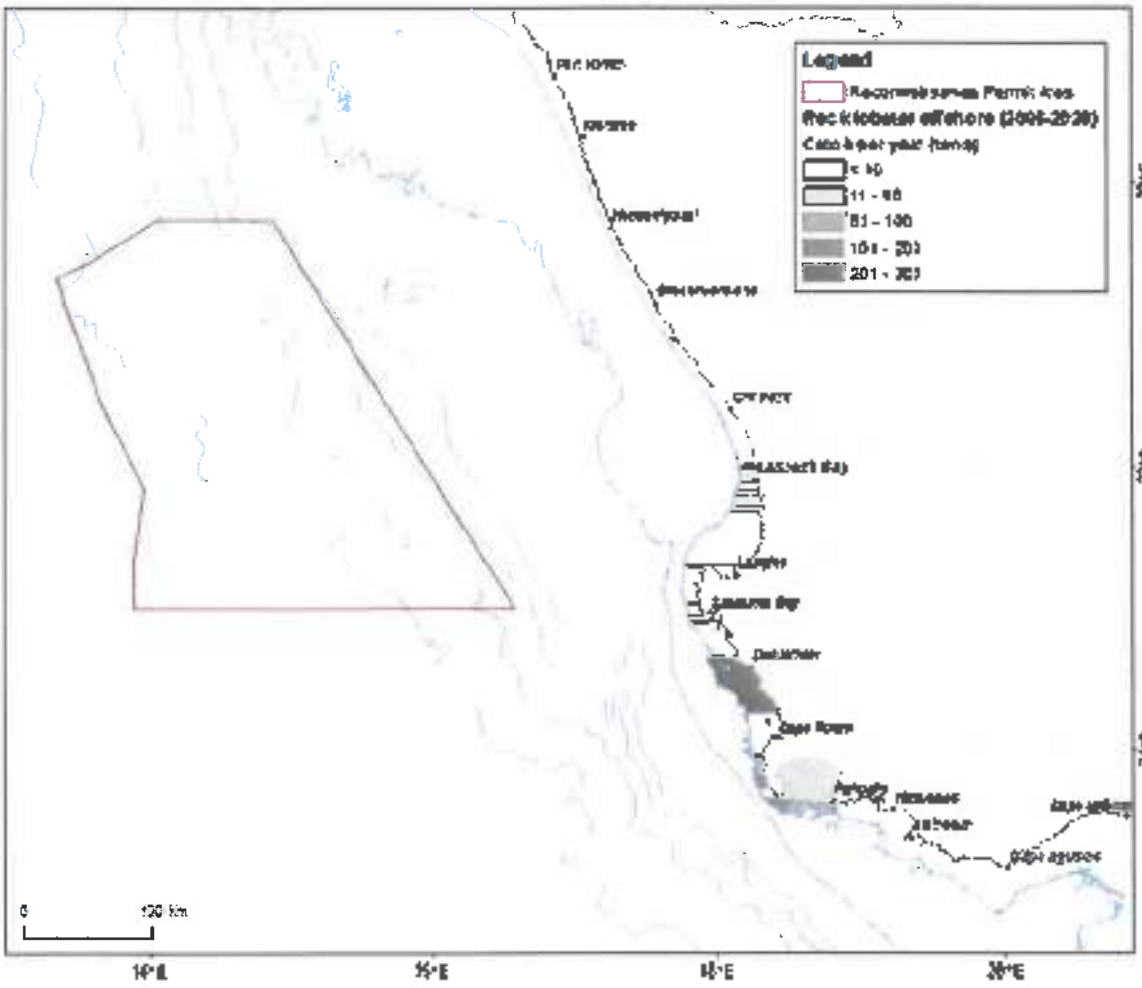

Figure 3.40: Spatial distribution of fishing effort expended by the west coast rock lobster offshore (trapboat) sector in relation to the Reconnaissance Permit application area.

3.3.10 SMALL-SCALE FISHERIES[5]

The concept of Small-Scale Fisheries (SSF) is a relatively new addition to the fisheries complexity in South Africa. The concept has its origin in a global initiative supported by the Food and Agricultural Organisation of the United Nations (FAO). In South Africa, there is a long history of coastal communities utilizing marine resources for various purposes. Many of these communities have been marginalized through apartheid practices and previous fisheries management systems. In 2007 government was compelled through an equality court order to redress the inequalities suffered by these traditional fishers[6]. The development of a SSF sector aims in part to compensate previously disadvantaged fishing communities that have been displaced either politically, economically or by the development of large-scale commercial fisheries. This led to the development of the Small-Scale Fisheries Policy (SSFP), the aim of which is to redress and provide recognition of the rights of small-scale fishers (DAFF, 2015). The

[5] In regard to SSF, this assessment is guided by several key documents, namely the Marine Living Resources Act of 1998 (as amended), the Small Scale Fisheries Policy (2016) and in particular the Small Scale Fisheries Regulations of 2016. See also : Small-Scale Policy implementation Plan available at http://www.smallscalefisheries.co.za/useful-resource

[6] See also the Thesis of Pretorius, G. (2022)

SSFP was gazetted in May 2019 under the Marine Living Resources Act, 1998 (Act No. 18 of 1998). It is only now (2021/2022) in an advanced process of implementation. It is a challenging process that has been exacerbated by the conflict and overlap with another fisheries-related process of fishing rights allocations (known as Fishery Rights Allocation Process or "FRAP"). As of February 2022, neither process has been concluded and the issues at stake are highly politicised. The SSF overlaps other historical fisheries in South Africa, leading to legal challenges where the SSF rights allocations are in conflict with other established commercial fishing sectors, most notably the commercial squid fishing sector. SSF is defined as a fishery although specific operations and dynamics are not yet fully defined as they are subject to an ongoing process by DFFE. The SSF regulations (DAFF, 2016) do however define the fishing area for SSF as "'near-shore', meaning "the region of sea (including seabed) within close proximity to the shoreline". The regulations further specify under Schedule 5 *Small-scale fishing areas and zones in which* "5. (1) In order to facilitate the establishment of areas where smallscale fishers may fish, the Department must set up a procedure to engage and consult with the small-scale fishing community in proposing demarcated areas that may be established as areas where small-scale fishers may fish" and which under section 5 (2)b. *"take into account the mobility of each species in the allocated basket of species with sessile species requiring smaller fishing areas while nomadic and migratory species requiring larger area.*

Small-scale fishers fish to meet food and basic livelihood needs, but may also directly be involved in fishing for commercial purposes[7]. These fishers traditionally operate on nearshore fishing grounds to harvest marine living resources on a full-time, part-time or seasonal basis. Fishing trips are usually of short-duration and fishing/harvesting techniques are labour intensive[8].

Small-scale fishers are an integral part of the rural and coastal communities in which they reside and this is reflected in the socio-economic profile of such communities. In the Eastern Cape, KwaZulu-Natal and the Northern Cape, small scale fishers live predominantly in rural areas while those in the Western Cape live mainly in urban areas (Harris et. al. 2002; Sunde & Pedersen C. 2007; Sunde 2016.).

Many communities living along the coast have, over time, developed local systems of rules to guide their use of coastal lands, forests and waters. These local rules are part of their systems of customary law. Rights to access, use, and own different natural resources arise from local customary systems of law. These systems of law are not written down as in Western law, but are passed down from generation to generation through practice (https://www.masifundise.org/wp-content/uploads/2011/06/vissernet-eng-news-3-final.pdf). South Africa's Constitution recognises customary law together with common law and state law. Section 39 (3) makes provision for a community that has a system of customary rights arising from customary law to be recognised as long as these rights comply with the Bill or Rights. In line with this, the SSFP also recognises rights arising in terms of customary law. Customary fishers are

[7] There is no formal designation of artisanal (or traditional/subsistence) fishing in South Africa, which is generally considered as fishing or resource extraction for own use. As fisheries have evolved and the commercial benefit realised, subsistence fishers have increasingly moved to commercialisation aimed at supporting their livelihoods. This group can now, therefore, also include shore and boat-based anglers and spear-fishers who target a wide range of fine fish species, some of which are also targeted by commercial operations, skin divers who collect rock lobsters and other subtidal invertebrates, bait collectors (mussels, limpets, red bait) and non-subsistence collectors of intertidal organisms. The high value of many intertidal and subtidal resources (e.g. rock lobster, abalone and mussels) has resulted in an increase in their production through aquaculture and small-scale harvesting in recent years (Clark et. al. 2010).

[8] The equipment used by small scale fishers includes rowing boats in some areas, motorized boats on the south and west coast and simple fishing gear including hands, feet, screw drivers, hand lines, prawn pumps, rods with reels, gaffs, hoop nets, gill nets, seine/trek nets and semi-permanently fixed kraal traps.

normally associated with discrete groups (tribes or communities with unique identities and associations with the sea) who may be defined by traditions and beliefs (see also Pretorius, 2022). These traditions are increasingly being challenged as stocks and marine resources have been depleted. This would include, for example, intertidal harvesting of seaweed, mussels, oysters, cephalopods and virtually any species available to these communities. These fishers are generally localised and do not range far beyond the areas in which they live[9].

SSF resources are managed in terms of a community-based co-management approach that aims to ensure that harvesting and utilisation of the resource occurs in a sustainable manner in line with the ecosystems approach. The SSF is to be implemented along the coast in series of community co-operatives. Only a co-operative is deemed to be a suitable legal entity for the allocation of small-scale fishing rights[10]. Applicants for small-scale fishing rights must have a historical involvement in traditional fishing operations, including the catching, processing or marketing of fish for a cumulative period of at least 10 years. They also need to show a historical dependence on deriving the major part of their livelihood from traditional fishing operations.

More than 270 communities have registered an Expressions of Interest (EOI) with the Department. DFFE has split SFF by communities into district municipalities and local municipalities. The location of these coastal communities and the number of fishers per community are shown in Figure 3.41.

- In the Northern Cape, there are 103 fishers registered in the Namakwa district, comprising the Richtersveld and Kamiesberg local municipalities.
- Western Cape districts include 1) West Coast (Berg River, Saldanha Bay, Cederberg, Matzikama and Swartland local municipalities; 2) Cape Metro; 3) Overberg (Overstrand and Cape Agulhas); and 4) Eden (Knysna, Bitou and Hessequa). In total there are 2748 fishers registered in the province.
- In the Eastern Cape, the communities are again split up, broadly as 1) Nelson Mandela Bay, 2) Sarah Baartman, 3) Buffalo City, 4) Amathole, 5) O.R. Tambo and 6) Alfred Nzo. There are 5154 fishers registered in the province.
- KwaZulu-Natal has 2008 registered small-scale fishers divided by district into 1) Ugu, 2) Ethekwini Metropolitan, 3) Ilembe, 4) King Shwetshayo/Uthungulu, and 5) Umkhanyakude.

Approximately 10 000 small-scale fishers have been identified around the coast. The licence block is situated offshore of the West Coast, City of Cape Town and Overberg municipal districts. Between Saldanha Bay and Cape Agulhas, 68 communities have been registered for small-scale fishing rights, these co-operatives comprise a total of 2031 fishers. At this point in time, no discreet co-operatives are active, except for on the West Coast in Port Nolloth.

The SSFP requires a multi-species approach to allocating rights, which entails the allocation of rights for a basket of species that may be harvested or caught within particular designated areas[11]. Section 6 of the regulations covers access *Management of the rights* of access and includes amongst other parts

Co-operatives can only request access to species found in their local vicinity. DFFE recommends five basket areas: 1. Basket Area A – The Namibian border to Cape of Good Hope – 57 different resources

[9] It can include foot-fishers, but also boat fishers who may have difficult or restricted options for launching sites. Note that in some areas fishers are increasingly using more sophisticated technology such as fish finders and larger motorised boats. This ability means their activities may be increasingly commercialised and may overlap with more established commercial fishery sectors.

[10] A co-operative is jointly owned and democratically controlled by small-scale fishers.

[11] Under the SSF regulations the species that may be included in the "basket" are provided in Annexures 2, 3 & 4 that includes fish species that are listed on the non-saleable list, and those that 2 shall only be caught for own consumption within the corresponding limits.

2. Basket Area B – Cape of Good Hope to Cape Infanta – 109 different resources 3. Basket Area C – Cape Infanta to Tsitsikamma – 107 different resources 4. Basket Area D – Tsitsikamma to the Pondoland MPA – 139 different resources 5. Basket Area E – Pondoland MPA to the Mozambican border – 127 different resources.

The mix of species to be utilised by small-scale fishers includes species that are exploited nearshore by existing commercial sectors viz; traditional linefish, west coast rock lobster, squid, hake handline[12], abalone, KZN beach seine, netfish (gillnet and beach-seine), seaweed and white mussel. An apportionment of TAE/TACs for these species will be transferred from existing commercial rights to SSF[13], whereas white mussels will become the exclusive domain of SSF. Species nominated for commercial use will be subject to TAE and/or TAC allocation. Species nominated for own use will be available to all members of a particular co-operative, but subject to output controls.

The small-scale fishery rights cover the nearshore area (defined in section 19 of the MLRA as being within close proximity of shoreline). Small-scale fishermen along the Northern Cape and Western Cape coastlines are typically involved in the traditional line, west coast rock lobster and abalone fisheries, whereas communities on the South Coast would be involved in traditional line, squid jig and oyster harvesting. The small-scale communities on the West Coast, with long family histories of subsistence fishing, prioritise the harvest of nearshore resources (using boats) over the intertidal and subtidal resources (Clark, Hauk et al. 2002, Harris, Salo, & Russell 2010).

Figure 3.41: Fishing boats outside the Hondeklipbaai small-scale community co-operative (photo credit Carika van Zyl).

[12] Hake handline is a small subsector of the hake fishery and requires a fishing right apportionment. The fishery has in recent years not been active because of resource availability. It is perceived as having potential for allocation as part of the SSF and as part of their "basket".

[13] DFFE proposes that, commencing January 2021, 50% of the overall TAE and TAC for the traditional linefish and abalone sectors, respectively, will be apportioned to small-scale fishing whereas 25% of the overall TAE for squid will be apportioned to small-scale fishing (DEFF 2020)

Snoek (*Thyrsites atun*), Cape bream / hottentot (*Pachymeropon blochii*) and yellowtail (*Seriola lalandi*) are important linefish species that are targeted by small-scale fishers operating nearshore along the West and South-West Coast of South Africa (refer to Section 3.3.8). Snoek are targeted by small-scale fishers during the snoek seasonal migration between April and June, during which time they shoal nearshore and are therefore available to handline fishermen[14]. Snoek availability coincides with peaks in the availability of other small pelagic species, notably anchovy and sardine (Nepgen, 1979). As shown by Crawford et al. (1987) [15][16] snoek stay inshore on their southward migration (see Figure 3.5) i.e. April through to June and then move offshore into deeper waters to spawn[17] in July and August (and are not available to linefishers).

Small-scale fishers also target west coast rock lobster (*Jasus lalandii*) using hoopnets set by small "bakkies" on suitable reefs at a water depth of less than 30 m. Fishing activity may range up to 100 m water depth by the larger vessels that participate in the offshore commercial rock lobster trap sector (refer to Section 3.3.9).

Small-scale fishermen along the Northern Cape and Western Cape coastlines are unlikely to range beyond 20 km from the coastline; thus, inshore of the Reconnaissance Permit area (refer to Figure 3.42). This assessment is however cognisant of the ongoing issues related to the perceived areas fished and species targeted by SSF off the West Coast of South Africa[18] e.g. that cultural practice of SSF may occur to 55 km offshore. While SSF regulations clearly specify that fishing is required to take place "nearshore" the actual differentiation between SSF and other fishing operations that might include SSF, such as the commercial "traditional linefish" and "pole and line" and the extent to which these commercial fisheries might include SSF, remains unclear. As such the offshore extent to which SSF may operate requires a precautionary approach in this assessment and consideration that the possibility exists (albeit a remote possibility that cannot be verified through the information made available on these fisheries), that SSF may have occurred historically and potentially in the future further offshore than suggested by the information made available for this assessment i.e. there is a remote possibility that some SSF may have targeted certain species (of which tuna and snoek are the main candidate

---

[14] Snoek are known to undertake migrations in a southward direction from the waters of the northern Benguela into the southern Benguela towards the cape west and southern coasts. These migrations have certainly been long taken advantage of by fishers, including traditional linefishers and communities along the west coast. Commercial fishers as well as the Small Scale Fishery (SSF) sector capitalise on the inshore availability, but this opportunity is lost once the snoek move offshore in mid-winter and start their northward migration. Snoek are primarily a "winter" fish, moving systematically southwards in autumn and commercial linefish, recreational and community-based boats exploit this shoaling species mostly in the nearshore. Snoek are also caught by the hake trawl fleets in significant numbers at times as snoek may undertake diurnal migrations feeding or spawning in deeper waters (and are not accessible to surface line fishers at these times). There is however no definitive description of snoek migrations with regard to their exact spatial and temporal movements.

[15] The Benguela ecosystem : Part IV. pgs 438

[16] See also Nepgen (1979) in Fish. Bull. S Afr, 12:35-43

[17] Snoek spawning occurs offshore during winter-spring, along the shelf break (150–400 m) of the western Agulhas Bank and the South African west coast. Prevailing currents transport eggs and larvae to a primary nursery ground north of Cape Columbine and to a secondary nursery area to the east of Danger Point; both shallower than 150 m. Juveniles remain on the nursery grounds until maturity, growing to between 33 and 44 cm in the first year (3.25 cm/month). Onshore-offshore distribution (between 5- and 150-m isobaths) of juveniles is determined largely by prey availability and includes a seasonal inshore migration in autumn in response to clupeoid recruitment. Adults are found throughout the distribution range of the species, and although they move offshore to spawn - there is some southward dispersion as the spawning season progresses - longshore movement is apparently random and without a seasonal basis (Griffiths, 2002). Refer to Figure 3.5.

[18] On 22/08/22 the Western Cape High Court ruled that the process of designating SSF in the Western Cape had been "unlawful" and had to be redone.

species) further offshore than 20 km. The distance fished offshore by SSF and the associated risks determined in this assessment further necessarily considers practical aspects, notably that bottom fishing is impractical in waters deeper than 100 m and as such any bottom fishing, whether SSF or commercial, is highly unlikely beyond a precautionary depth being the 100 m depth contour. Further, in regard to migratory species, such as longfin tuna and snoek, economic and regulatory aspects relating to distances fished offshore is pertinent [i.e. such as the requirements of the South African Maritime Safety Authority (SAMSA)] in particular that most SSF are not likely to be "B" class certified (i.e. can operate up to 40 nm offshore and are longer than 9m) are likely limited to "C" class being mainly vessels of <9 m[19] permitted to only operate < 15 nm offshore.

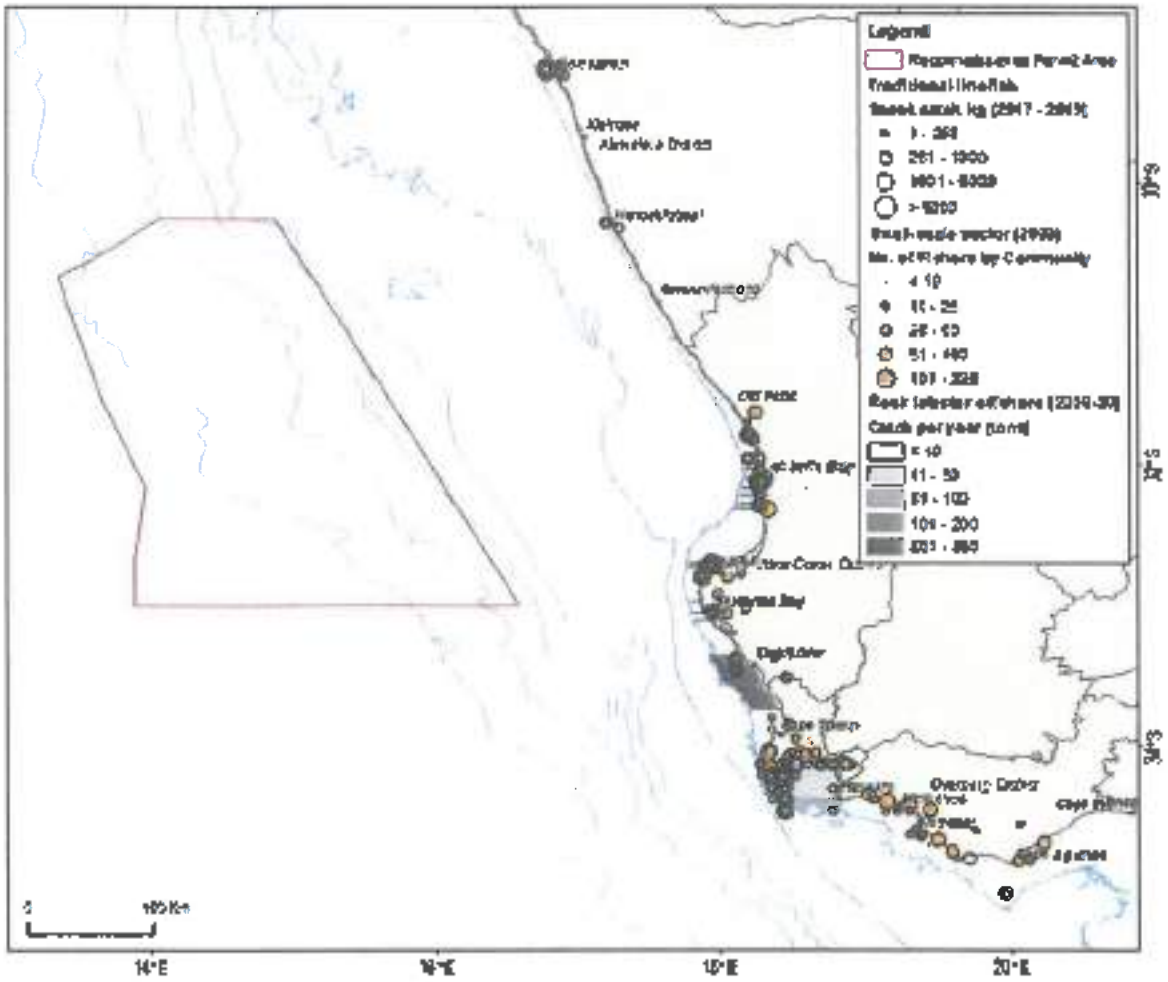

Figure 3.42: Overview of spatial distribution of small-scale fishing communities and number of participants per community along the South African west coast. The location of snoek catches reported by the linefish sector for the period 2017 to 2019 are shown.

3.3.11 BEACH-SEINE AND GILLNET FISHERIES (NETFISH)

There are a number of active beach-seine and gillnet operators throughout South Africa (collectively referred to as the "netfish" sector). Initial estimates indicate that there are at least 7 000 fishermen active in fisheries using beach-seine and gillnets, mostly (86%) along the West and South coasts. These fishermen utilize 1 373 registered and 458 illegal nets and report an average catch of about 1 600 tons annually, constituting 60% harders (also known as mullet, *Chelon richardsonii*), 10% St Joseph shark (*Callorhinchus capensis*) and 30% "bycatch" species such as galjoen (*Dichistius capensis*), yellowtail (*Seriola lalandii*) and white steenbras (*Lithognathus lithognathus*). Catch-per-unit-effort declines eastwards from 294 and 115 kg·net-day^{-1} for the beach-seine and gill-net fisheries respectively off the West Coast to 46 and 5 kg·net-day^{-1} off KwaZulu-Natal. Consequently, the fishery changes in nature from a largely commercial venture on the West Coast to an artisanal/subsistence fishery on the East Coast (Lamberth *et al.* 1997).

Figure 3.43: An example of a typical Sestern Cape "trek-net" (beach-seine) operation (Source: https://www.iol.co.za/capetimes/news/picture-essay-being-hooked-on-fishing-no-easy-way-of-life-14145539).

The fishery is managed on a Total Allowable Effort (TAE) basis with a fixed number of operators in each of 15 defined areas (see Table 3.12 for the number of rights issued and Figure 3.44 for the fishing areas). The number of Rights Holders operating on the West Coast from Port Nolloth to False bay is listed as 28 for beach-seine and 162 for gillnet (DEFF, 2020). Permits are issued solely for the capture of harders, St Joseph and species that appear on the 'bait list'. The exception is False Bay, where Right Holders are allowed to target linefish species that they traditionally exploited.

Table 3.12: Recommended Total Allowable Effort (TAE, number of rights and exemption holders) and rights allocated in 2016-17 for each netfish area. Levels of effort are based on the number of fishers who could maintain a viable income in each area (DAFF 2017).

Area	Locality	Beach-seine	Gillnet	Total	Rights allocated

A	Port Nolloth	3	4	7	4
B	Hondeklipbaai	0	1	1	0
C	Olifantsriviermond-Wadrifsoutpansmond	2	8	10	4

OE	Olifants River Estuary	0	45	45	45

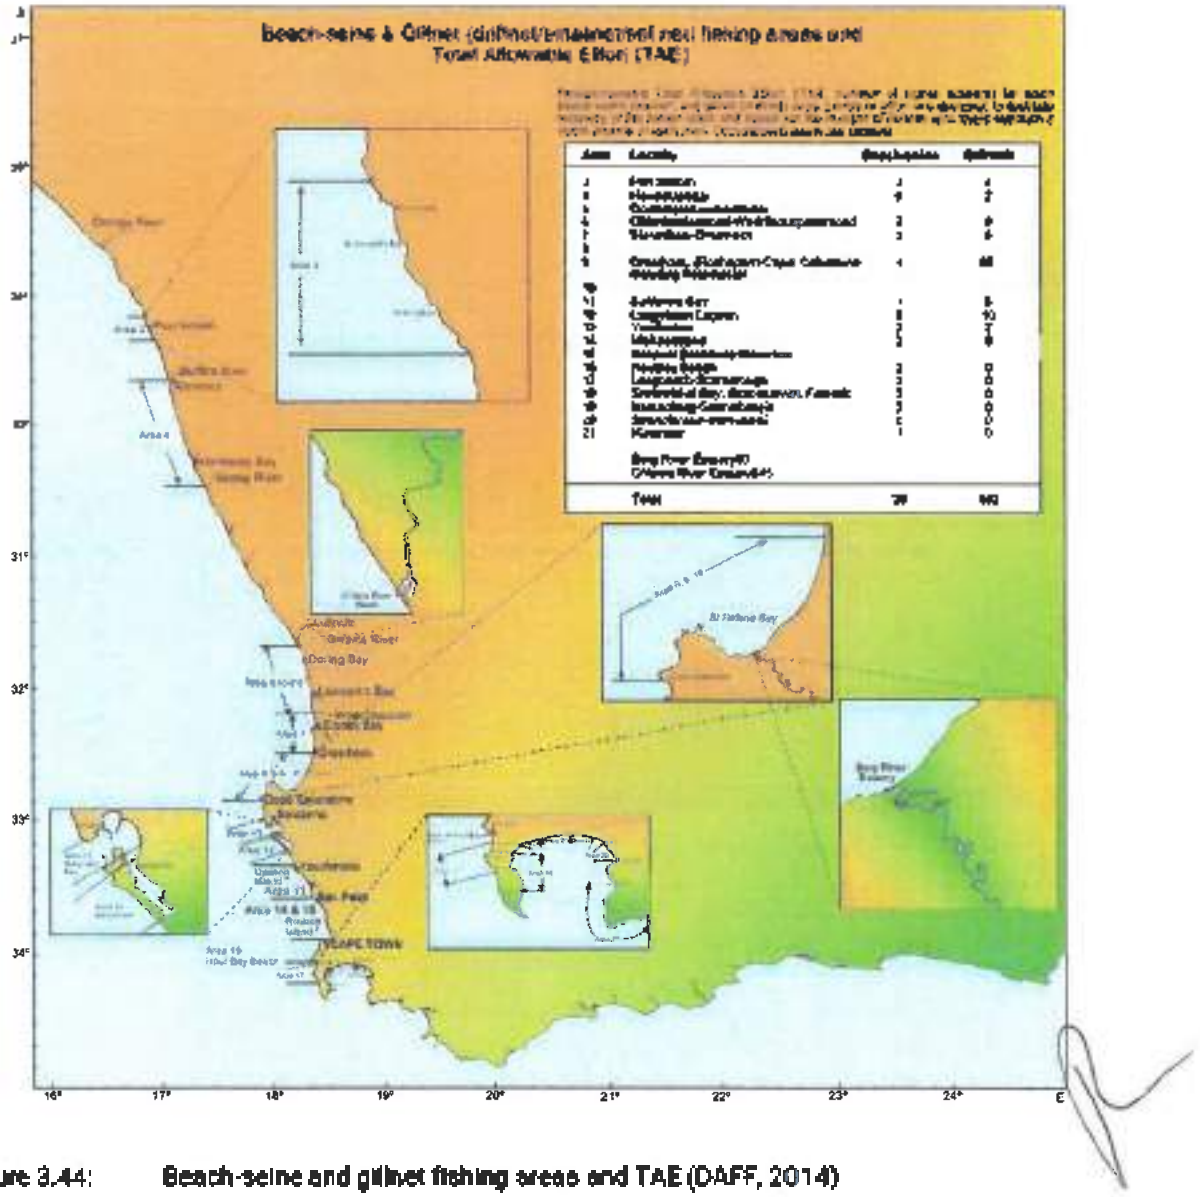

Figure 3.44: Beach-seine and gillnet fishing areas and TAE (DAFF, 2014)

The beach-seine fishery operates primarily on the West Coast of South Africa between False Bay and Port Nolloth (Lamberth 2006) with a few permit holders in KwaZulu-Natal targeting mixed shoaling fish during the annual winter migration of sardine (Fréon *et al.* 2010). Beach-seining is an active form of fishing in which woven nylon nets are rowed out into the surf zone to encircle a shoal of fish. They are then hauled shorewards by a crew of 6–30 persons, depending on the size of the net and length of the haul. Nets range in length from 120 m to 275 m. Fishing effort is coastal and net depth may not exceed 10 m (DAFF 2014b).

The gillnet fishery operates from Yzerfontein to Port Nolloth on the West Coast. Surface-set gillnets (targeting mullet) are restricted in size to 75 m x 5 m and bottom-set gillnets (targeting St Joseph shark) are restricted to 75 m x 2.5 m (da Silva *et al.* 2015) and are set in waters shallower than 50 m. The spatial distribution of effort is represented as the annual number of nets per kilometre of coastline.

The range of gillnets (50 m) and that of beach-seine activity (20 m) will not overlap with Reconnaissance Permit area. Figure 3.45 shows the expected range of gillnet fishing activity off the west coast of South Africa, situated at least 220 km from the Reconnaissance Permit area.

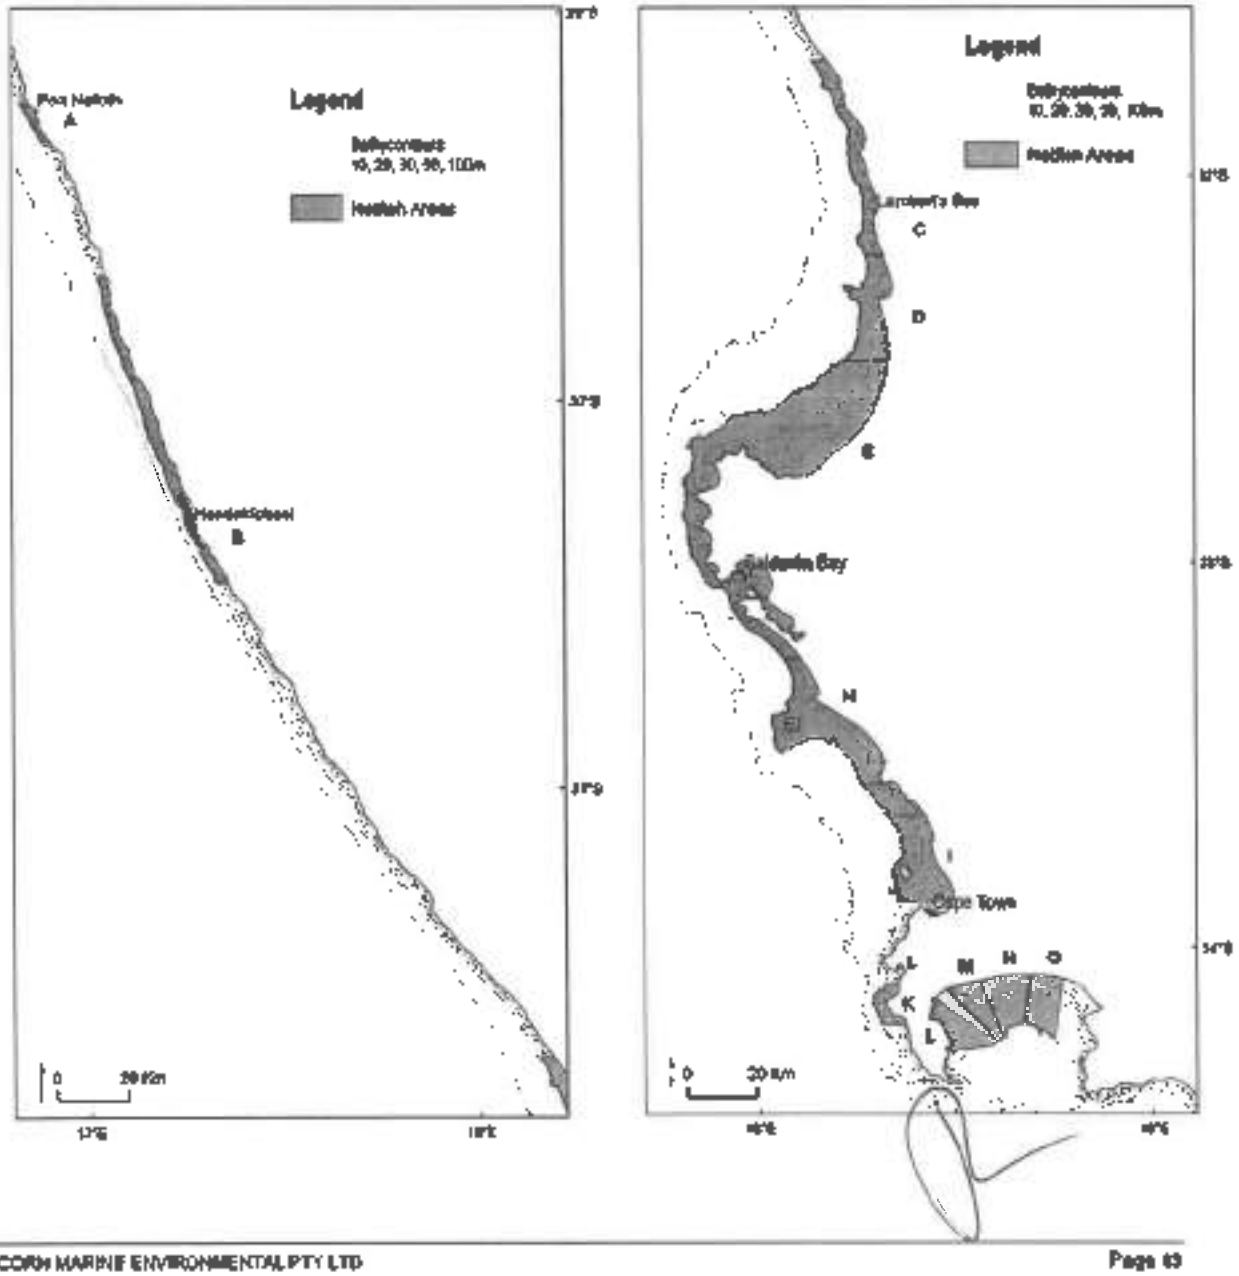

Figure 3.45: Netfish (gillnet and beach-seine) fishing areas (DAFF, 2016/17)

3.3.12 FISHERIES RESEARCH

Swept-area trawl surveys of demersal fish resources are carried out twice a year by DAFF in order to assess stock abundance. Results from these surveys are used to set the annual TACs for demersal fisheries. First started in 1985, the West Coast survey extends from Cape Agulhas (20°E) to the Namibian maritime boarder and takes place over the duration of approximately one month during January/February. The survey of the Southeast coast (20°E – 27°E longitude) takes place in April/May. Following a stratified, random design, bottom trawls are conducted to assess the biomass, abundance and distribution of hake, horse mackerel, squid and other demersal trawl species on the shelf and upper slope of the South African coast. Trawl positions are randomly selected to cover specific depth strata that range from the coast to the 1 000 m isobath. On occasion, trawls are targeted in waters deeper than 1 000 m. Figure 3.46 shows the distribution of research trawls undertaken in relation to the Reconnaissance Permit area, with several deepwater trawls having been undertaken within the area.

The biomass of small pelagic species is assessed bi-annually by an acoustic survey. The first of these surveys is timed to commence in mid-May and runs until mid-June while the second starts in mid-October and runs until mid-December. The timing of the demersal and acoustic surveys is not flexible, due to restrictions with availability of the research vessel as well as scientific requirements. During these surveys the survey vessels travel pre-determined transects (perpendicular to bathymetric contours) running offshore from the coastline to approximately the 200 m isobaths, but selected transect run to the to 1 000 m contour in places. The surveys are designed to cover an extensive area from the Orange River on the West Coast to Port Alfred on the East Coast and the DFFE survey vessel progresses systematically from the Northern border Southwards, around Cape Agulhas and on towards the east. Figure 3.46 shows the research effort undertaken off the West Coast during the November 2020 spawner biomass survey and May 2021 recruitment survey of small pelagic species. The Reconnaissance Permit area is situated at least 60 km offshore of the deepwater extent of research survey transects and there is no spatial overlap expected.

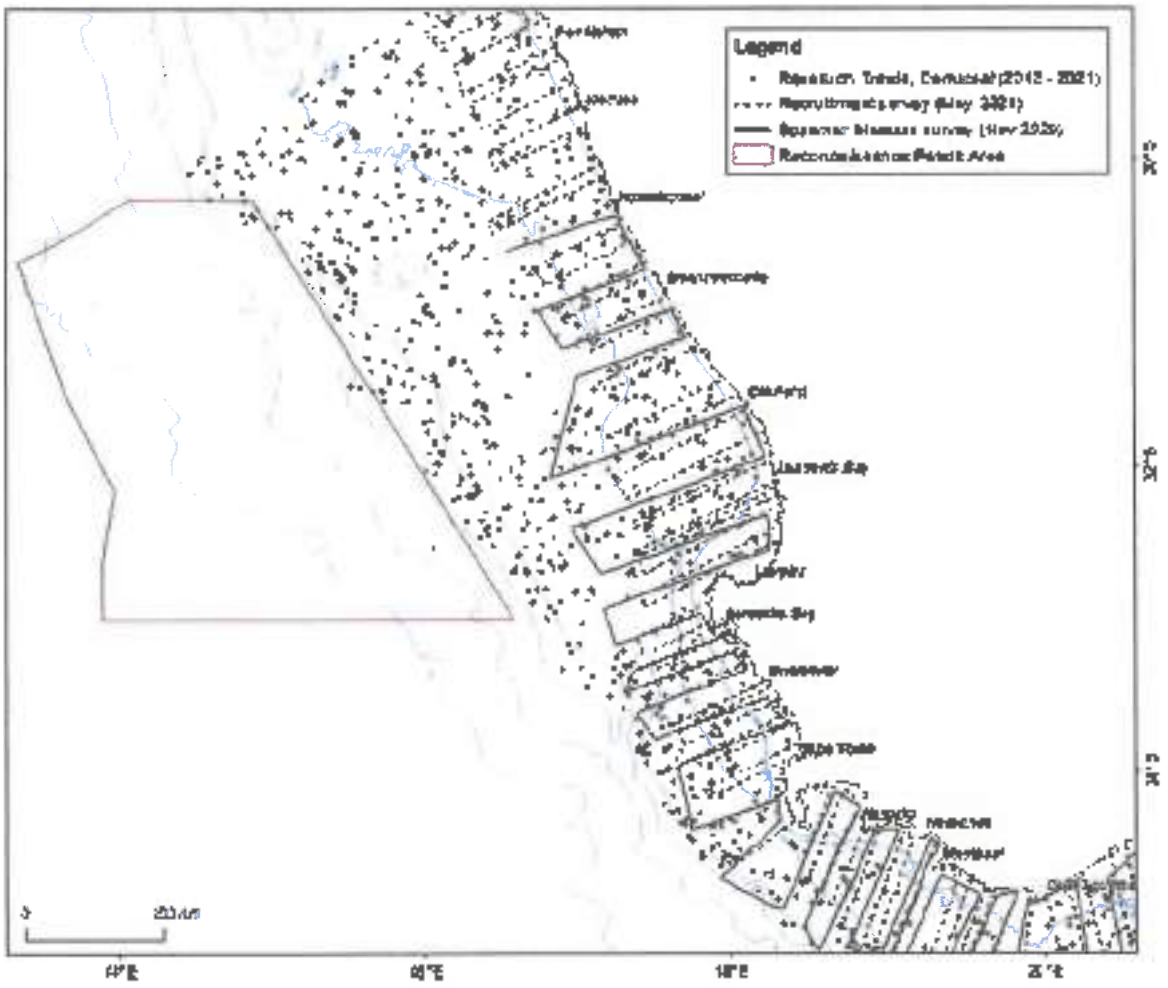

Figure 3.46: Spatial distribution of trawl start positions undertaken by DFFE from 2013 to 2021 to assess the biomass of demersal fish species along the West Coast. Also shown are the survey transects of recruitment and spawner biomass research surveys undertaken by DFFE in May 2021 and November 2020, respectively, in relation to the Reconnaissance Permit application area.

3.4 SUMMARY OF SEASONALITY IN FISHERIES

The seasonality of each of the main commercial fishing sectors that operate off the west coast (west of 20°E) of South Africa is indicated in Table 3.13. Fishing intensity within the Reconnaissance Permit application area is presented for each sector in Table 3.14.

Table 3.13: Summary table showing seasonal variation in fishing effort expended by each of the main commercial fisheries sectors operating off the West Coast of South Africa.

Sector	Fishing Intensity by Month (H = High, M = Low to Moderate, N = None)

4 IMPACT ASSESSMENT

4.1 EXCLUSION FROM FISHING GROUNDS

Description and Source of Impact

The project activities that will result in exclusion to fishing grounds are listed below.

Activity phase	Activity
Mobilisation	N/A

Activity phase	Activity
Operation	Operation of survey vessel with seismic array
Demobilisation	N/A

A purpose-built seismic vessel would be contracted to conduct the 3D seismic survey. The acoustic source (airgun array) would consist of up to 20 active airguns with an overall operating pressure of 2 000 pound-force per square inch (psi). The acoustic source would be situated approximately 50 m behind the seismic vessel at 7 m to 8 m below the water surface. The receiver array for the 3D survey would consist of up to 10 streamer cables, 8 km in length, towed in parallel with a separation of 150 m. The streamer cables would be towed at a depth of between 6 m and 10 m and would therefore not be visible to other vessels. A tailbuoy would mark the far end of each of the streamer cables and would be marked by AIS.

Figure 4.1: Schematic diagram showing side-view of the airgun array and hydrophone cable ("streamer") towed in a 2D seismic survey.

The acquisition of high quality seismic data requires that the position of the survey vessel and the array be accurately known. Seismic surveys consequently require accurate navigation of the sound source over pre-determined survey transects. This, and the fact that the airgun array and the hydrophone streamer need to be towed in a set configuration behind the tow-ship, means that the survey operation has little manoeuvrability whilst operating. For this reason, the vessel is considered as a fixed marine feature that is to be avoided by other vessels.

The safety zones aim to ensure the safety of navigation, avoiding or reducing the probability of damage to the towed streamer cables. The temporary exclusion of vessels from entering the safety zone around a seismic survey vessel poses a direct impact to fishing operations in the form of loss of exclusion from fishing grounds.

Project Controls

Under the Convention on the International Regulations for Preventing Collisions at Sea (COLREGS, 1972, Part A, Rule 10), a seismic survey vessel that is engaged in surveying is defined as a "vessel restricted in its ability to manoeuvre" which requires that power-driven and sailing vessels give way to a vessel restricted in her ability to manoeuvre. In addition to a statutory 500 m safety zone, a seismic contractor would request a safe operational limit (that is greater than the 500 m safety zone) that it would like other vessels to stay beyond. Typical safe operational limits for 2D and 3D surveys are illustrated in Figure 4.2.

A safety zone would be enforced around the seismic vessel for the duration of the project, resulting in the temporary exclusion of fishing operations in the vicinity of this zone around the vessel and towed array. The dimensions of the exclusion would be approximately 6 Nm ahead and astern and 2 Nm to

either side of the survey vessel, resulting in a safety zone of approximately 165 km² around the survey vessel.

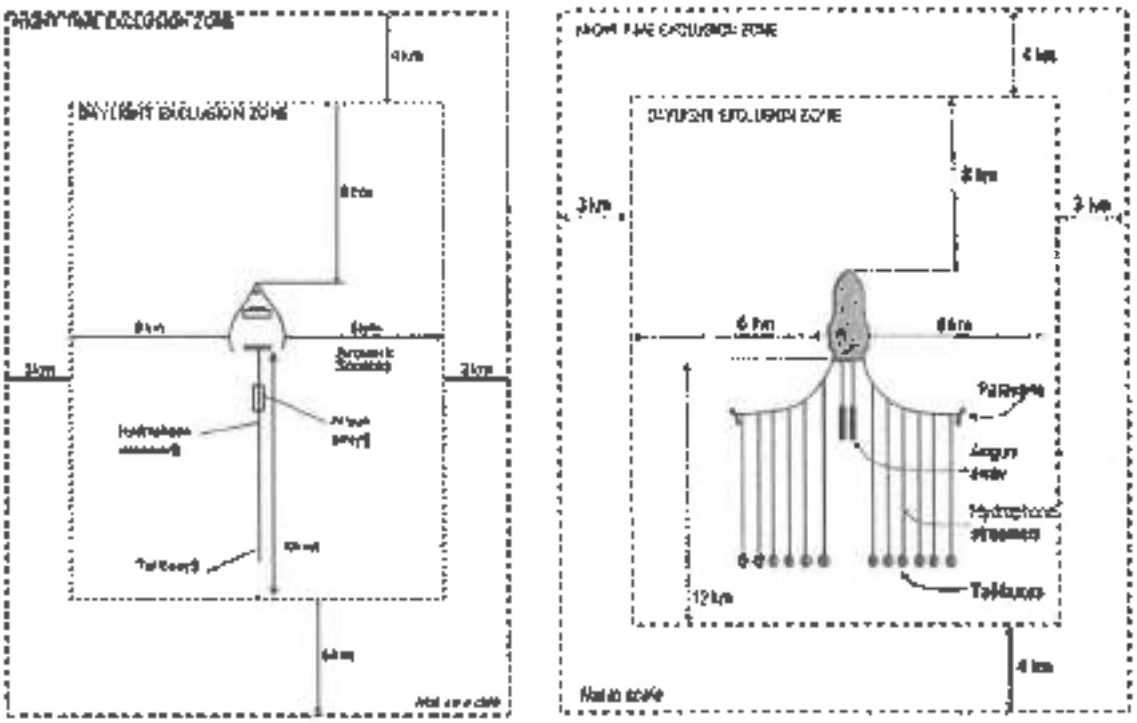

Figure 4.2 Typical configuration and safe operational limits for a 2D (left) and 3D (right) seismic survey operation (SLR Consulting).

The 500 m safety zone and proposed safe operational areas would be communicated to key stakeholders well in advance of the proposed seismic survey. During the survey, notice of the exclusion zone would be issued as a Coastal Navigational Warning (CNW) and/or NAVAREA warning via NAVTEX by the South African Navy Hydrographic Office (SANHO).

At least one escort vessel equipped with appropriate radar and communications would be used to patrol the area during the seismic survey to ensure that other vessels adhere to the safe operational limits. The support vessel would assist in alerting other vessels (e.g. fishing, transport, etc.) about the proposed survey and the lack of manoeuvrability of the seismic vessel.

During adverse weather conditions, the survey vessel may move outside of the boundaries of the seismic acquisition area. Although the acoustic source would not be active during production downtime, it is unlikely that the towed array would be retrieved during these times, meaning that an exclusion zone would still be required.

Sensitivity of Receptors

Sensitivity herein considers the extent of fishing ground, ability of the fishing industry to operate as expected considering a project-induced change to their normal fishing operations (linked in part to fishing gear type and vessel manageability), as well as the vulnerability of the targeted fish species.

An overview of the South African fishing industry and a description of each commercial sector is presented in Sections 3.1 and 3.3. The affected fisheries sectors (receptors) have been identified based

on the extent of overlap of fishing grounds with the seismic acquisition area. Only the large pelagic longline sector operates across the extent of the Reconnaissance Permit area, with activity increasing towards the continental shelf break. Tuna pole-line vessels would be expected to operate seasonally (February/March) in the vicinity of the Reconnaissance Permit area (inshore of licence area) but there likelihood that vessels would be active in the area itself is considered to be low.

Sensitivity herein considers the extent of the fishing ground and the ability of a particular sector to operate as expected considering a project-induced change to their normal fishing operations. The vulnerability of a particular fishing sector to the impact of the safety zone would differ according to the degree of disruption to that particular type of fishing operation. The current assessment considers this to be related to the type of gear used and the probability that the fishing operation can be relocated away from the affected area into alternative fishing areas. For instance, the pelagic longline sector deploys sets unanchored, baited lines which drift with the surface water currents. These are set for an extended period before being recovered by the vessel. Gear may cover a large area during this time and may become entangled with a towed seismic array. Whilst setting or hauling a longline the vessel's manoeuvrability is restricted. Thus, a vessel cannot easily manoeuvre out of the way of an approaching survey vessel.

For this reason, as well as the proportion of catch and effort in the Reconnaissance Permit area, the sensitivity of the large pelagic longline sector is considered to be high[20]. The sensitivity of the tuna pole-line sector, which is a mobile operation, and has an overall low proportion of spatial overlap with the survey area, has been rated as low[21]

Impact Assessment

Based on the location of the Reconnaissance Permit application area, there is no impact of exclusion from fishing grounds expected on the demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, linefish, west coast rock lobster or small-scale fisheries. There is a high probability that the large pelagic longline sector (targeting tuna, swordfish and shark) will experience loss of access to fishing ground over the duration of the proposed 70 day survey. Although the Reconnaissance Permit area is situated offshore of the continental shelf break, this being an area of peak fishing activity, there is a high probability that vessels and drifting lines could be expected within the Reconnaissance Permit area. The extent of the impact is considered to be regional due to the large area (57 400 km^2) within which the survey could take place[22]. The impact of exclusion is assessed to be of high magnitude[23]. Based on the combination of extent, duration and magnitude of the impact, and considering the high probability that the impact would occur, the overall significance of the impact is considered to be MEDIUM NEGATIVE. Due to the low probability of the operations of the tuna pole-line sector within the Reconnaissance Permit area, the overall significance of the impact on the sector is considered to be LOW NEGATIVE.

[20] Receptors are not resilient to Project impacts and will not be able to adapt to such changes without substantive adverse consequences.

[21] Receptors are not fully resilient to Project impacts but are generally able to adapt to such changes.

[22] Also noting that during a 3D seismic survey the vessel would acquire the data progressively across the designated area i.e. the area of exclusion area is localised at any one point in time. However, the impact rating has been assessed based on the cumulative impact of exclusion across the full extent of the Reconnaissance Permit area.

[23] Where fishing operations in the affected area could temporarily cease

Mitigation

The potential for mitigation includes effective communications with fishing sectors which could allow vessel operators the opportunity to plan fishing operations in areas unaffected by the presence of the survey vessel. During survey operations, it may be possible for operators to relocate fishing effort into areas of the Reconnaissance Application area that are unaffected by the presence of the survey area if adequate and up-to-date survey information is provided on a daily and/or weekly basis to key fishing fleets. Furthermore, it is recommended that the survey is timed to avoid taking place during the months of high seasonal fishing activity by the large pelagic longline sector, this being the months of June and July (refer to Figure 3.28). A Fisheries Liaison Officer (FLO) should be present on site for the duration of the survey, either stationed on board the survey vessel or the escort vessel. Such a person should be familiar with the types of fisheries sectors in the region i.e. knowledge of the types of operations and gear in use, as well as be able to communicate in the local languages of English and Afrikaans.

Table 4.1:Recommended Measures to Mitigate the Impact of Exclusion on Fishing Operations.

No.	Mitigation Measure
1	Timing of the seismic survey to avoid periods of peak fishing activity during June and July is recommended in order to reduce the probability of disruption to the large pelagic longline fishing sector.
2	At least three weeks prior to the commencement of seismic survey activities the following key stakeholders should be consulted and informed of the proposed seismic survey programme (including navigational co-ordinates of location, timing and duration of proposed activities) and the likely implications thereof (specifically the exclusion and safety zone around the seismic vessel): Fishing industry associations: SA Tuna Association; SA Tuna Longline Association, Fresh Tuna Exporters Association, South African Deepsea Trawling Industry Association (SADSTIA), South African Hake Longline Association (SAHLLA). Other key stakeholders: South African Navy Hydrographic Office (SANHO), South African Maritime Safety Association, Ports Authority and the DFFE Vessel Monitoring, Control and Surveillance Unit in Cape Town. These stakeholders should again be notified at the completion of the project when the survey and support vessels are off location.
3	Request, in writing, the SANHO to broadcast a navigational warning via Navigational Telex (Navtex) and Cape Town radio for the duration of the seismic survey activity. Distribute a Notice to Mariners prior to the commencement of the seismic survey operations. The Notice to Mariners should give notice of (1) the co-ordinates of the survey area, (2) an indication of the proposed survey timeframes, (3) the dimensions of the towed gear array and dimensions of the safety zone around the seismic vessel, and (4) provide details on the movements of support vessels servicing the project. This Notice to Mariners should be distributed timeously to fishing companies and directly onto vessels where possible.
4	An experienced Fisheries Liaison Officer (FLO) should be placed on board the seismic or escort vessel to facilitate communications with fishing vessels in the vicinity of the seismic survey area.
6	The lighting on the seismic and support vessels should be managed to ensure that they are sufficiently illuminated to be visible to fishing vessels, as well as ensure that it is reduced to a minimum compatible with safe operations.
7	Ensure project vessels fly standard flags and lights to indicate that they are engaged in towing surveys and are restricted in manoeuvrability.
7	Notify any fishing vessels at a radar range of 12 nm from the seismic vessel via radio regarding the safety requirements around the seismic vessel.
8	Implement a grievance mechanism in case of disruption to fishing or navigation.

Residual Impact

This potential impact cannot be eliminated because the seismic vessels are needed to undertake the survey and a safety zone will be enforced around the vessel during routine operations. Timing the survey to avoid taking place during the months of June and July (periods of seasonally high fishing effort; see Figure 3.28) could lead to a residual impact of LOW NEGATIVE significance on the large pelagic longline sector (see Table 4.2).

Table 4.2: Impact of Exclusion of the Large Pelagic Longline Sector from access to Fishing Ground.

Impact of Exclusion of Large Pelagic Longline Operations within the Reconnaissance Permit area		
Aspect	Rating	Residual Impact

4.2 IMPACT OF SOUND ON CATCH RATES

Source of Impact

The project activities that can result in an impact on catch rates are listed below.

Activity phase	Activity
Mobilisation	N/A
Operation	Seismic acquisition operations
Demobilisation	N/A

The airgun array for the 3D seismic survey is proposed to be the Sercel G-Gun II 2 620 CUI Source Array. The array consists of 20 active airgun units, has a towing depth of 6.0 m and an operating pressure of 2 000 pounds per square inch (PSI).

The primary output of a seismic airgun source typically has most of the energy in the frequency bandwidth between 5 and 300 Hz. The maximum sound pressure levels at the source of airgun arrays in use today in the seismic industry are in the range 230-255 dB re 1 µPa at 1 m, with the majority of their produced energy being low frequency of 10-100 Hz (McCauley 1994; NRC 2003). For the current project, the peak sound pressure levels (Pk SPL) for the 3D array is expected to be 256.4 dB re 1 µm @ 1m. The sound exposure levels (SEL) is expected to be 232.4 dB re 1 µm @ 1m

Description of Impact

In addition to the potential impacts of exclusion to fishing areas, international research has shown that the noise energy generated during seismic surveys may cause mortality, physiological damage, masking effects and/or behavioural responses in fish and invertebrates (Carroll *et al* 2017). As such, the possible effects of seismic sound on species relevant South African fisheries are considered. Differences in morphology and behaviour between species means that species vary in their vulnerability to seismic noise, and generalisations across groups are not easily made. The potential impact of elevated underwater sound on fish can be grouped into four types of affects:

- **Mortality or lethal effects:** life-threatening physical injuries, including death and severe physical injury. Fish mortality is associated with very high source noise levels and fish in close proximity to the noise source (for example, underwater explosions). Susceptibility to mortality at a particular sound level can vary between fish species, for example shellfish and fish without swim bladders can typically survive higher noise levels.
- **Physical (or physiological) effects:** non-life-threatening physical injuries, such as temporary or permanent auditory damage. The type and severity of physiological effects at different noise

levels can differ between species. Some fish detect and respond to sound predominantly by detecting particle motion in the surrounding fluid while others are capable of detecting sound pressure via the gas bladder.

- **Masking effects:** the reduction in the detectability of a sound as a result of the simultaneous occurrence of another noise. Masking noise interferes with the ability of the animal to detect and respond to biologically important sounds.
- **Behavioural effects:** include perceptual, stress and indirect effects, of which the most common are startle responses or avoidance of an area. Behavioural responses can vary between species and sometimes extend over large distances, until the noise decreases below the background sound level.

Summarised below are some of the main findings relevant to the assessment of effects on fisheries:

- Generally, fish species with specialisations for sound pressure detection (e.g. swim bladder) have lower sound pressure thresholds and respond at higher frequencies than fishes lacking these morphological adaptations.
- Evidence suggests that pelagic species have more sensitive hearing (thresholds at lower frequencies) than demersal species.
- Cartilaginous fishes (e.g. sharks) have the highest sensitivity to low frequency sound (~20 Hz to ~1500 Hz) (Myrberg, 2001). Since this group lacks a swim bladder, their detection capabilities are restricted to the particle motion component of sound (Myrberg, 2001; Casper et al., 2012).
- A range of damaging physical effects due to airgun noise have been described for fish, including swim-bladder damage, transient stunning, short-term stress responses, temporary hearing loss, haemorrhaging, eye damage and blindness. However, studies have shown that physical damage to fish caused from seismic sources occurs only in the immediate vicinity of the airguns, in distances of less than a few meters (Gausland 2003).
- Adult and juvenile fish have been shown to display several behavioural responses to seismic sound. These include leaving the area of the sound source by swimming away and changing depth distribution, changing schooling behaviour and startle responses to short range start up. Behavioural responses to seismic sound could lead to decreased catch rates if fish move out of important fishing grounds (Hirst and Rodhouse 2000).
- Studies indicate that offshore seismic survey activity had no effect on catch rates of crustaceans in the surrounding area (Andriguetto-Filho et al. 2005; Parry & Gason 2006), and little effect on reef invertebrates (crustaceans, echinoderms and molluscs) exposed to commercial seismic airgun noise (Wardle et al. 2001).
- The abundance and spatial distribution of fish and invertebrate larvae and eggs is highly variable and dependent on factors such as fecundity, seasonality in production, tolerances to temperature, length of time spent in the water column, hydrodynamic processes and natural mortality. Due to their importance in commercial fisheries, numerous studies have been undertaken experimentally exposing the eggs and larvae of various species to airgun sources (reviewed in McCauley, 1994). Physiological effects on eggs and larvae of a seismic array have been demonstrated to a distance of 5 m from the acoustic source (Kostyuchenko 1971). When compared with total population sizes and natural daily mortality rates, the impact of seismic sound sources on fish eggs and larvae could be considered insignificant (McCauley, 1994; Dalen and Maested 2008). The wash from ships propellers and bow waves can be

3228

expected to have a similar, if not greater, volumetric effect on plankton than the sounds generated by airgun arrays.

- For squid and other cephalopods a 2 - 5 km zone of acoustic influence is assumed around the acoustic source point.

Threshold levels for underwater noise impacts on fish have been the subject of research over many years, however much of that research has focused on the potential for physiological effects (injury or mortality) rather than on quantifying and relating noise levels with behavioural effects. A review of the literature and guidance on appropriate thresholds for assessment of underwater noise impacts is provided in the 2014 Acoustical Society of America (ASA) Technical Report *Sound Exposure Guidelines for Fishes and Sea Turtles* (Popper et al., 2014)[24].

The ASA Technical Report includes thresholds for mortality (or potentially mortal injury) as well as degrees of impairment such as temporary or permanent threshold shifts (TTS or PTS, indicators of hearing damage). Separate thresholds are defined for peak noise and cumulative impacts (due to continuous or repeated noise events) and for different noise sources (e.g. explosives, pile driving, and continuous vessel noise, drilling or dredging). In relation to fish behavioural impacts, the ASA Technical Report includes a largely qualitative discussion, focusing on long term changes in behaviour and distribution rather than startle responses or minor movements. The ASA qualitative approach to responses to seismic airguns includes definitions of effects at three distances from the source defined in relative terms: Near (N): this distance typically refers to fish within tens of meters from the noise source; Intermediate (I): distances within hundreds of meters from the noise source; and Far (F): fish within thousands of meters (kilometres) from the noise source. The risk is described qualitatively as low, moderate or high.

Sensitivity and hearing range is highly variable amongst fish species. Fish species which may be affected by underwater disturbances may broadly be grouped into three categories; cartilaginous fish without gas-filled chambers or swim bladders, fish with swim bladders where hearing is independent of gas-filled chambers or swim bladders, and lastly fish which are most sensitive to sound pressure through otophysic connections between pressure receptive organs and the inner ear (Carroll *et al.* 2017). Data indicates that fish possessing a swim bladder are more sensitive to impulsive sounds, such as those generated by airguns, than fish without swim bladders (Popper *et al.*, 2014). Table 4.4 lists the peak SPL and cumulative SEL at which different types of effects have been identified for each of these categories of fish (Popper *et al.*, 2014). Based on these noise exposure criteria, relatively high to moderate behavioural risks to fish without a swim bladder are expected at near to intermediate distances (tens to hundreds of meters) from the source location. Relatively low behavioural risks are expected at far field distances (thousands of meters) from the source location. For fish species with a swim bladder that is involved in hearing, relatively high behavioural risk is expected at near to intermediate distances, and moderate behavioural risk at far field distances from the source.

Studies have shown that physical damage to fish caused from acoustic sources occurs only in their immediate vicinity, in distances of less than a few meters (Gausland 2003). Whilst adult fish can flee from this noise, eggs and larvae are unable to do so and therefore may be affected by an acoustic pulse.

As a general guideline, the sound ranges of 161 to 166 dB re 1 µPa RMS may be used as a suitable indicator sound pressure level at which behavioural modifications of fish start to take place. Behavioural effects are generally short-term, however, with duration of the effect being less than or equal to the

[24] See also: Hawkins, A.D., Pembroke, A.E. and A.N. Popper. 2014. Information gaps in understanding the effects of noise on fishes and invertebrates. Rev Fish Biol Fisheries (2015) 25:39-64

228

duration of exposure, although these vary between species and individuals, and are dependent on the properties of the received sound.

Table 4.4: Noise exposure criteria for seismic airguns and acoustic thresholds for fish (Popper et al., 2014)

Type of animal	Mortality and potential mortal injury	Impairment			Behaviour
		Recovery injury	TTS	Masking	
Fish: no swim bladder (particle motion detection)	>219 dB SEL_{24hr} or >213 dB Pk SPL	>216 dB SEL_{24hr} or >213 dB Pk SPL	>>186 dB SEL_{24hr}	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder is not involved in hearing (particle motion detection)	210 dB SEL_{24hr} or >207 dB Pk SPL	209 dB SEL_{24hr} or >207 dB Pk SPL	>>186 dB SEL_{24hr}	(N) Low (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder involved in hearing (primarily pressure detection)	207 dB SEL_{24hr} or >207 dB Pk SPL	203 dB SEL_{24hr} or >207 dB Pk SPL	186 dB SEL_{24hr}	(N) Low (I) Low (F) Moderate	(N) High (I) High (F) Moderate
Fish eggs and fish larvae	>210 dB SEL_{24hr} or >207 dB Pk SPL	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) Low (I) Low (F) Low	(N) Moderate (I) Low (F) Low

Notes: peak sound pressure levels (Pk SPL) dB re 1 µPa; Cumulative sound exposure level (SEL_{24hr}) dB re 1 μPa^2-s. Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

Behavioural responses to impulsive sounds are varied and include leaving the area of the noise source (Dalen and Raknes 1985; Dalen and Knutsen 1987; Løkkeborg 1991; Skalski et al. 1992; Løkkeborg and Soldal 1993; Engås et al. 1996; Wardle et al. 2001; Engås and Løkkeborg 2002; Hassel et al. 2004), changes in depth distribution and feeding behaviour (Chapman and Hawkins 1969; Dalen 1973; Pearson et al. 1992; Slotte et al. 2004), spatial changes in schooling behaviour (Slotte et al. 2004), and startle response to short range start up or high level sounds (Pearson et al. 1992; Wardle et al. 2001). Behavioural responses could lead to decreased catch rates if fish move out of important fishing grounds (Hirst and Rodhouse 2000) or if they reduce interest in bait or change fish's behaviour such that usual capture methods are less effective (Hirst & Rodhouse, 2000). Table 4.4 provides a summary list of studies showing reductions in catch rates of fish during and after seismic surveys.

The observed declines in catch rates differed considerably from study to study as did the distance from the seismic sound source at which reductions in catch rates were measured. Hirst and Rodhouse (2000) compiled the results of a number of results from experiments, which indicated a range from 1 km to greater than 33 km. The observed duration of impacts ranged from approximately 12 hours to up to 10 days. Variability in findings is related to the sensitivity of different fish species to noise, the gear-type used across different fisheries, and abiotic factors e.g. water depth, which affects the transmission of sound in water. Table 4.5 summarises catch reductions for Atlantic cod (*Gadus morhua*), haddock (*Melanogrammus aeglefinus*) and rockfish (*Sebastes spp.*).

Table 4.5: Summary list of studies showing evidence of a reduction in fish catch rates as a result of seismic survey activity (Council, A.M.C. 2014).

Species	Gear type	Noise level of seismic testing	Catch reduction	Source
Atlantic cod (*Gadus morhua*)	Trawl	250 dB	46-69% lasting at least 5 days	Engas et al. 1993
	Longline	250 dB	17-45% lasting at least 5 days	Engas et al. 1993
	Longline	Undetermined, 9.32 miles from source	55-79% lasting at least 24 hours	Løkkeborg and Soldal, 1993
Haddock (*Melanogrammus aeglefinus*)	Trawl	250 dB	70-72% lasting at least 5 days	Engas et al. 1993
	Longline	250 dB	49-73% lasting at least 5 days	Engas et al. 1993
Rockfish (*Sebastes* spp.)	Longline	223 dB	52% - effect period not determined	Skalski et al. 1992

Avoidance effects or behavioural alterations from seismic surveys involving many fish species do not automatically imply risk factors and thus do not necessarily cause a disturbance to the fishery[26] (McCauley et al., 2000). A recent large-scale experiment conducted by Meekan *et al.* (2021) in Australia showed no short-term or long-term effects on the abundance or behaviour of demersal fish assemblages in response to a commercial seismic source. This suggests that seismic surveys have little impact on demersal fishes. Other studies that found no evidence of significant changes in catch rates or fish abundance include Hassel et al. 2004, Picket *et al.* 1994, Miller and Cripps 2013 and Thomson *et al.* 2014.

A Sound Transmission Loss Modelling (STLM) study for the proposed activities was undertaken by SLR in order to forecast sound levels of various metrics, including peak sound pressure levels (Pk SPLs), root-mean-square sound pressure levels (RMS SPLs), and single-pulse and cumulative sound exposure levels (SELs) at receiving locations within and adjacent to the proposed survey area. These noise levels were used to estimate the threshold distances to potential sound effects on marine species of interest, including fish.

The following components were included in the model:

- Airgun source modelling – modelling of the sound energy emissions from Source Array proposed to be used in the survey, including its far-field signature and power spectral density (PDS), as well as the beam pattern of the source array;
- Short-range modelling – prediction of the received noise levels over a range of up to four kilometres from the selected array source locations at various depths, in order to investigate sound field variations due to the water depth changes. Short range modelling is used to assess the potential high-risk immediate noise impact to marine fauna species of interest;
- Long-range modelling – prediction of the received noise levels over a range of up to two hundred kilometres from the selected array source locations. This modelling assesses the noise impacts from the survey on relevant far-field sensitive marine areas; and

[26] For example, a study conducted by Wardle et al. (2001) monitored the behaviour of fish and invertebrates on a rocky Scottish reef. Here a video system was used to observe potential responses and seismic acoustic source blasts were carefully calibrated to have a peak level of 210 dB re 1 µPa at 15 m from the source and 195 dB re 1 µPa at 109 m from the source. Only minor behavioural responses to seismic activity was observed. However, no animals appeared to leave the reef and more importantly, no permanent changes in the behaviour of the fish or invertebrates on the reef was observed. Meekan et al. (2021), found no evidence to suggest that the use of a commercial seismic source affects the abundance, size-structure, behaviour, or movement of demersal fishes.

- Cumulative noise exposure modelling – prediction of the received cumulative SELs over a 24-hour period (SEL24hr) for selected representative survey scenarios adjacent to marine sensitive areas, to assess the potential cumulative noise impact to marine fauna species of interest.

The results of the STLM study (SLR 2021) were used to identify zones of impact for fish species (amongst other marine fauna species of concern) based on relevant noise impact assessment criteria. The noise effects assessed included physiological effects (physical injury/permanent threshold shift (PTS) and temporary threshold shift (TTS)) and behavioural disturbance due to either immediate impact from single airgun pulses or cumulative effects of exposure to multiple airgun pulses over a period of 24 hours. Table 4.6 outlines the predicted maximum SELs and the estimated Pk SPLs and RMS SPL across the water column for all azimuths as a function of horizontal distance from the seismic airgun source array, for water depth range within the proposed survey area, based on the short range SEL modelling results of the report.

Table 4.6: The maximum SELs, Pk SPLs and RMS SPL across the water column for all azimuths as a function of distance from the source array for water depth range within the survey area (SLR, 2021)

Horizontal distance from the source array, m	The predicted maximum levels across the water column for all azimuths, for water depth range within the survey area (2D/ 3D)		
	SEL, dB re 1 µPa²·s	Pk SPL, dB re 1µPa	RMS SPL, dB re 1µPa
10	209 / 206	230 / 231	227 / 225
20	202 / 201	223 / 224	220 / 218
50	195 / 193	216 / 217	213 / 211
90	191 / 189	212 / 213	209 / 207
100	189 / 187	210 / 211	207 / 205
200	183 / 181	204 / 205	199 / 197
500	174 / 172	195 / 196	186 / 184
800	172 / 169	193 / 194	183 / 181
1 000	169 / 167	190 / 190	179 / 177
2 000	162 / 159	183 / 184	171 / 169
4 000	155 / 153	176 / 177	162 / 160

Project Controls

The Seismic contractor will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and BAT regarding fisheries management.

Sensitivity of Receptors

Sensitivity herein considers the extent of fishing ground, ability of the fishing industry to operate as expected considering a project-induced change to their normal fishing operations (linked in part to fishing gear type and vessel manageability), as well as the vulnerability of the targeted fish species.

The greatest risk of physiological injury from seismic sound sources is for species with swim-bladders (e.g. hake and other demersal species targeted by demersal longline and demersal trawl fisheries). In many of the large pelagic species, swim-bladders are either underdeveloped or absent and the risk of physiological injury through damage of this organ is therefore lower (Pisces, 2021). However, two of the four tuna species targeted in South African fisheries, *Thunnus albacares* (yellowfin) and *T. obesus* (bigeye), do have swim bladders (Collette & Nauen, 1983) and so may be physically vulnerable.

203

In the case of the large pelagic longline and tuna pole-line sectors, the targeted fish stock may only be available in a specific area for a specific period of time. Relocation to an alternative area may not be viable as the preferred area is predicated on the resource being available at a specific time and place.

The sensitivity of the large pelagic longline sector is considered to be high. Noise levels are expected to drop to below threshold levels for behavioural disturbance before reaching areas fished by the remaining sectors viz. demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, traditional linefish, west coast rock lobster, small-scale fisheries and netfish sectors (beach-seine and gillnet).

Impact Assessment

The zones of impact on fish of impulsive signal emissions from the array source are presented in Table 4.7. The results relate only to physiological effects on fish. The zones of potential injuries were predicted to be within 160 m from the 3D array for fish species with a swim bladder and 80 m for fish species without a swim bladder. The zone of potential impact was predicted to be within 160 m for fish eggs and larvae.

Based on the noise exposure criteria provided by Popper et al. (2014) for fish that use a swim bladder for hearing, relatively high behavioural risks are expected at near to intermediate distances (tens to hundreds of meters) from the source location. Relatively moderate behavioural risks are expected for at far field distances (thousands of meters) from the source location.

The cumulative sound fields based on one assumed 24-hour survey operation were modelled and the zones of cumulative impact (i.e. the maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels) are presented in Table 4.6. The zones of potential mortal injuries for fish species with and without a swim bladder, and for fish eggs and larvae are predicted to be within 50 m from the survey lines. For recoverable injury, the zones of impact are predicted to be within 20 m from the survey lines for fish without a swim bladder, and within 200 m for fish with a swim bladder. The zones of TTS effect for fish species with and without swim bladders are predicted to be within 3.5 km from the survey lines for the 3D survey 24-hour operation scenarios considered.

Existing experimental data regarding recoverable injury for fish eggs and larvae is sparse and no guideline recommendations have been provided. However, based on a subjective approach, noise impacts for fish eggs and larvae are expected to be moderate at the near field (i.e. in the distance of tens of meters) from the source location, low at intermediate (i.e. in the distance of hundreds of meters) and far field (i.e. in the distance of thousands of meters) from the source location.

Table 4.7: Zones of immediate impact from single pulses (2D / 3D seismic airgun arrays) for mortality and recoverable injury for fish, fish eggs and fish larvae (SLR, 2021).

Type of animal	Zones of impact – maximum horizontal distances from source to impact threshold levels			
	Mortality and potential mortal injury		Recovery injury	
	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m
Fish: no swim bladder (particle motion detection)	> 213	70 / 80	>213	70 / 80

Fish eggs and fish larvae	210	20 / 30	-	-	-	-

Pulfrich (2022) concluded that the impact of the acoustic source on fish eggs and larvae accounts for an insignificant amount of mortality compared to the natural mortality rate per day for most fish species at that life stage. The Reconnaissance Permit area does not coincide with spawning areas of key commercial fish species.

The overall effects on the fishing industry of physiological injury to fish as a result of the proposed surveys is considered to be of overall LOW NEGATIVE significance (with mitigation) on the large pelagic longline sector, the only sector that operates within the Reconnaissance Permit application area.

The zones of impact of pulsed sounds on behavioural responses of fish were not modelled in the STLM because of the variability in published findings on the topic. However, if a precautionary approach is adopted, a sound range of 161 to 166 dB re 1 µPa RMS may be used as an indicator of the sound

pressure level at which behavioural modifications of fish start to take place. The STLM results predict a RMS SPL of 162 dB re 1µPa at a horizontal distance of 4 km from the airgun array (SLR 2021). For the purposes of this assessment, we have assumed that the catch rates to a distance of 4 km from the Reconnaissance Permit area could be affected. Based on the location of the Reconnaissance Permit area, the noise generated during the survey would be expected to the large pelagic longline and tuna pole-line sectors. Because the sector operates across the extent of the Reconnaissance Permit area, the affected area is considered to be of regional extent. Behavioural effects are generally immediate, with duration of the effect being less than or equal to the duration of exposure.

The noise generated during the survey would be expected to attenuate to below threshold levels for behavioural disturbance before reaching the fishing grounds of all other sectors viz. demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, traditional linefish, west coast rock lobster, small-scale fisheries and net fisheries. The Reconnaissance Permit area does not overlap with spawning areas of key commercial species (and the timing of the proposed survey is not expected to coincide with peak spawning periods).

Noise would be expected to attenuate to below threshold levels for behavioural disturbance before reaching inshore recruitment and/or nursery areas. Due to the location of the Reconnaissance Permit area in the deepwater environment, sound generated during the survey is not expected to influence the spawning behaviour or migration route of snoek (a species of key importance to the linefish and small-scale fisheries sectors). The Reconnaissance Permit area is situated well offshore of the shelf break which is where snoek are known to spawn during winter-spring.

The impact of sound on the large pelagic longline sector is assessed to be of overall MEDIUM NEGATIVE significance before mitigation, whereas the impact on the tuna pole-line sector is assessed to be of overall LOW NEGATIVE significance. Due to the distance of the Reconnaissance Permit area from fishing grounds, the sound is likely to attenuate to below threshold levels for behavioural disturbance of all other fisheries sectors viz. the demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, traditional linefish, west coast rock lobster, small-scale fisheries and netfish sectors. There is no impact expected on these sectors.

Mitigation

The potential for mitigation includes effective communications with fishing sectors which could allow vessel operators the opportunity to plan fishing operations in areas unaffected by the presence of the survey vessel. During survey operations, it may be possible for operators to relocate fishing effort into areas of the Reconnaissance Application area that are unaffected by the presence of the survey area if adequate and up-to-date survey information is provided on a daily and/or weekly basis to key fishing fleets. The mitigation measure proposed in the marine faunal assessment report (Pulfrich 2022) is that the sound source should be ramped up to full operating volume over a period of 20 minutes (termed a "soft-start") thus allowing fish to avoid potential physiological injury. It is unlikely that this would mitigate effects on catch rates in the wider area. Furthermore, it is recommended that the survey is timed to avoid taking place during the months of high seasonal fishing activity by the large pelagic longline sector, this being the months of June and July (refer to Figure 3.28). A Fisheries Liaison Officer (FLO) should be present on site for the duration of the survey, either stationed on board the survey vessel or the escort vessel. Such a person should be familiar with the types of fisheries sectors in the region i.e. knowledge of the types of operations and gear in use, as well as be able to communicate in the local languages of English and Afrikaans. A list of proposed mitigation measures is included in Table 4.9.

Table 4.9: Recommended Mitigation Measures for Noise Effects on Fisheries.

No.	Mitigation measure
1	The seismic survey should avoid taking place during periods of peak fishing activity (June and July) in order to reduce the probability of disruption to the large pelagic longline fishing sector.
2	At least three weeks prior to the commencement of seismic survey activities the following key stakeholders should be consulted and informed of the proposed seismic survey programme (including navigational co-ordinates of location, timing and duration of proposed activities) and the likely implications thereof (specifically the exclusion and safety zone around the seismic vessel): Fishing industry associations: SA Tuna Association; SA Tuna Longline Association and Fresh Tuna Exporters Association. Other key stakeholders: SANHO, SAMSA, National Ports Authority and the DFFE Vessel Monitoring, Control and Surveillance Unit in Cape Town. These stakeholders should again be notified at the completion of the project when the survey and support vessels are off location.
3	Request, in writing, the broadcast by SANHO of a navigational warning via Navigational Telex (Navtex) and Cape Town radio for the duration of the seismic survey activity. Distribute a Notice to Mariners prior to the commencement of the seismic survey operations. The Notice to Mariners should give notice of (1) the co-ordinates of the survey area, (2) an indication of the proposed survey timeframes, (3) the dimensions of the towed gear array and dimensions of the safety zone around the seismic vessel and (4) provide details on the movements of support vessels servicing the project. This Notice to Mariners should be distributed timeously to fishing companies and directly onto vessels where possible.
4	An experienced Fisheries Liaison Officer (FLO) should be placed on board the seismic or escort vessel to facilitate communications with fishing vessels in the vicinity of the seismic survey areas.
5	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if during daylight hours it is confirmed visually by the MMO during the pre-shoot watch (60 minutes) that there are no shoaling large pelagic fish within 500 m of the seismic source.
6	In the case of shoaling large pelagic fish being observed within the mitigation zone, delay the "soft-start" until animals are outside the 500 m mitigation zone. Terminate seismic shooting on • Observation of slow swimming large pelagic fish (including whale sharks, basking sharks, and manta rays) within the 500 m mitigation zone. • Observation of any obvious mass mortalities of fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO to be as a direct result of the survey. For slow swimming large pelagic fish, terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required).
7	For the duration of the survey, circulate a daily survey schedule (look-ahead), via email, to key fishing associations.
8	Establish a functional grievance mechanism that allows stakeholders to register specific grievances related to operations, by ensuring they are informed about the process and that resources are mobilized to manage the resolution of all grievances, in accordance with the Grievance Management procedure.

Residual Impact

With the implementation of recommended mitigation measures, the residual impact of sound generated during the proposed survey is assessed to be of LOW NEGATIVE overall significance to the large pelagic longline and tuna pole-line sectors. There is no impact expected on the demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, traditional linefish, west coast rock lobster, small-scale and netfish sectors.

4.3 UNPLANNED EVENTS

4.3.1 ACCIDENTAL RELEASE OF OIL AT SEA

Description and Source of Impact

The project activities that could result in an accidental release of diesel / oil are listed below are provided below:

Project phase	Activity
Mobilisation	Vessel accident
Operation	Bunkering of fuel
	Vessel accident
Demobilisation	Vessel accident

These activities are described further below:

- Small instantaneous spills of marine diesel at the surface of the sea can potentially occur during operation during bunkering and such spills are usually of a low volume.
- Larger volume spills of marine diesel could occur in the event of a vessel collision or vessel accident.

Oil spilled in the marine environment would have an immediate detrimental effect on water quality, with toxic effects potentially resulting in mortality (e.g. suffocation and poisoning) or sub-lethal (e.g. respiratory damage) effects on marine fauna. An oil spill can also result in several indirect impacts on fishing. These include:

- Exclusion of fisheries from polluted areas and displacement of targeted species from normal feeding / fishing areas, both of which could potentially result in a loss of catch and / or increased fishing effort;
- Mortality of animals (including eggs and larvae) leading to reduced recruitment and loss of stock (e.g. mariculture); and
- Gear damage due to oil contamination.

Oil contamination could potentially have the greatest impact on commercial fisheries for rock lobster and sessile filter feeders (e.g. mussels) and grazers (e.g. abalone). Mortality is expected to be high on filter feeders and, to a lesser extent, grazers. These species have low mobility and no means to escape contamination and ultimately mortality. Thus, mariculture facilities could be impacted if a spill extended into these areas. For a large oil spill, fishing / mariculture activities and revenues could be affected over a wide area until such time as the oil has either been dispersed or broken down naturally.

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and best available techniques. The primary mitigation measure for avoiding the impacts of an accidental oil spill is to prevent any such spill from taking place. This is done through both technology applications, as well as operational controls. An escort vessel with appropriate radar and communications will be used during the operation to warn vessels that are in danger of breaching the safety/exclusion zone.

In the event of a spill incident, the project will implement an emergency response system to mitigate the consequences of the spill.

- Regulation 37 of MARPOL Annex I will be applied, which requires that all ships of 400 gross tonnage and above carry an approved Shipboard Oil Pollution Emergency Plan (SOPEP). The purpose of a SOPEP is to assist personnel in dealing with unexpected discharge of oil, to set in motion the necessary actions to stop or minimise the discharge, and to mitigate its effects on the marine environment.
- Project vessels will be equipped with appropriate spill containment and clean-up equipment, e.g. dispersants and absorbent materials. All relevant vessel crews will be trained in spill clean-up equipment use and routine spill clean-up exercises.

Sensitivity of Receptors

The sensitivity of the various fishing sectors that operate in the Reconnaissance Permit area is considered to be medium, as a diesel slick would be blown in a north-westerly direction due to the dominant winds and currents off the West Coast, remaining at the surface for less than 36 hours (PRDW 2013). Both Saldanha Bay and St Helena Bay support nearshore mariculture activities. These activities are far removed from the Reconnaissance Permit area and as such the sensitivity for mariculture is considered to be medium.

Impact assessment

The Reconnaissance Permit area coincides with fishing grounds used by the large pelagic longline sector only. Thus, any spill within the Reconnaissance Permit application area, could impact this sector. The dominant wind and current direction will ensure that any spill in the survey area is dispersed in a north-westerly direction away from the more actively fished areas inshore of the Reconnaissance Permit application area. An offshore spill is likely to disperse rapidly (days). Without the implementation of mitigation measures, the potential impact on the offshore fishing sectors is considered to be of local extent for small instantaneous spills, of regional for larger volume spills and of moderate magnitude in the short-term. The potential impact on commercial fishing operations is assessed to be of LOW NEGATIVE significance due to the improbable likelihood of such an event occurring.

In the case of a spill *en route* to the survey area (i.e. during a vessel accident), the spill may reach the coastline. Nearshore fishing (linefish and small-scale fisheries) and mariculture operations (abalone and mussel) would be at risk of the effects of an oil spill (refer to the marine fauna assessment report (Pulfrich, 2022)). The greatest risk of contamination is on sessile filter feeding (e.g. mussels and oysters) and grazing species (e.g. abalone) via physical clogging and or direct absorption of the contaminant, leading to mortality.

Mitigation Measures

Recommended mitigation measures are provided in Table 4.12.

Table 4.12: Recommended mitigation measures for Accidental Release of Oil at Sea.

No.	Mitigation measure
Oil Spills	
1	Ensure personnel are adequately trained in both accident prevention and immediate response, and resources are available on each vessel.
2	Obtain permission from DFFE to use low toxicity dispersants. Use cautiously.
3	Ensure adequate resources are provided to collect and transport oiled birds to a cleaning station.
Bunkering at sea	
4	Ensure offshore bunkering is not undertake in the following circumstances: • Wind force and sea state conditions of ≥6 on the Beaufort Wind Scale; • During any workboat or mobilisation boat operations; • During helicopter operations; • During the transfer of in-sea equipment; and • At night or times of low visibility.
Equipment	
5	Ensure that solid streamers rather than fluid-filled streamers are used. Alternatively, low toxicity fluid-fill streamers could be used.

Residual Impact

With the implementation of the above-mentioned intrinsic mitigation measures (refer to Table 4.12), the residual impact would be of LOW NEGATIVE significance for offshore or for nearshore spills (see Table 4.13).

Table 4.13: Impact of Accidental Release of Oil at Sea on Fisheries Sectors.

Impact on fisheries of accidental release of oil at sea

4.3.2 LOSS OF EQUIPMENT AT SEA

Description and Source of Impact

The project activities are provided below:

Project phase	Activity
Mobilisation	N/a
Operation	Accidental loss of equipment to the water column or seabed
Demobilisation	N/A

These activities (or event) are described further below:

- Irretrievable loss of equipment to the seabed during seismic acquisition; and
- Accidental loss of paravanes, streamers, arrays, and tail buoys during seismic acquisition.

During seismic acquisition, the survey vessel tows a substantial amount of equipment; the deflectors or paravanes, which keep the streamers equally spread are towed by heavy-duty rope, and the streamers themselves are towed by lead-in cables. Each streamer is fitted with a dlit float at the head of the streamer, numerous streamer mounts (birds and fins) to control streamer depth and lateral positioning, and a tail buoy to mark the end of the streamer. Streamers are neutrally buoyant at the required depth, but have buoyancy bags embedded within them that inflate at depth. If streamers are accidentally lost, they would float in the water column for some time before sinking. Dlit floats and tail buoys would ultimately be dragged down under the weight of the streamer. Airguns are suspended under floats by a network of ropes, cables, and chains, with each float configuration towed by an umbilical. Should both the float and umbilical fail, the airguns would sink to the seabed.

The potential impacts (direct) associated with lost equipment include:

- Potential snagging of demersal gear with regards to equipment that sinks to the seabed; and
- Potential entanglement hazards with regards to lost streamers, arrays and tail buoys drifting on the surface or in the water column.

Project Controls

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice. All gear will be recovered after the survey, unless lost to sea.

Sensitivity of Receptors

Sensitivity here refers to the ability of the sector to operate as expected considering a project-induced events. Floating equipment (e.g. streamer) may become entangled with fishing gear (e.g. pelagic longlines). Thus, the sensitivity of fishing gear to lost equipment is considered to be medium.

5228

Impact Assessment

The accidental loss of equipment onto the seafloor would provide a localised area of hard substrate in an area of otherwise unconsolidated sediments. The Reconnaissance Permit area does not coincide with fishing grounds of any demersal fishing sectors thus snagging of demersal gear is considered to be unlikely.

The loss of streamers and floats could result in entanglement hazards in the water column before the streamers sink under their own weight. In the unlikely event of streamer loss, associated impact could be highly localised and limited to the site (although would potentially float around regionally) over the short-term. The impact magnitude for equipment lost to the water column is, therefore, considered to be low and of LOW NEGATIVE significance to the large pelagic longline fishery.

Mitigation Measures

The following measures are recommended:

Table 4.14: Recommended Mitigation Measures for Loss of Equipment at Sea.

No.	Mitigation measure
1	Ensuring that loads are lifted using the correct lifting procedure and within the maximum lifting capacity of the crane system
2	Minimise the lifting path between vessels.
3	Undertake frequent checks to ensure items and equipment are stored and secured safely on board each vessel.
4	Retrieval of lost objects / equipment, where practicable, after assessing the safety and metocean conditions. Establish a hazards database listing the type of gear left on the seabed and / or in the survey area with the dates of abandonment / loss and locations and, where applicable, the dates of retrieval.
5	Notify SAHRO of any hazards left on the seabed or floating in the water column, and request that they send out a Notice to Mariners with this information.
6	Ensure at a minimum, one FLO person (speaking English and Afrikaans) is on board each escort vessel to facilitate communication in the local language with the fishing vessels that are in the area.

Residual Impact Assessment

The implementation of the mitigation measures (refer to Table 4.14) will reduce the impact; however, the residual impact will remain of low magnitude and of LOW NEGATIVE significance (refer to Table 4.15).

Table 4.15: Impact on Fisheries Sectors of Loss of Equipment at Sea.

Impact of Loss of Equipment at Sea		
Aspect	Rating	Residual Impact
Nature	Negative	Negative
Extent	Regional (Extends between 5 and 50 km from the site)	Regional (Extends between 5 and 50 km from the site)
Duration	Short term (1 – 5 year)	Immediate (<1 year)
Magnitude/Intensity	Low (Fishing process slightly altered)	Low (Fishing process slightly altered)
Reversibility	Reversible (Without incurring significant time or cost)	Reversible (Without incurring significant time or cost)
Probability	Improbable (<25% likelihood of occurring)	Improbable (<25% likelihood of occurring)
Significance	Low Negative (The impact is unlikely to be a significant risk)	Low Negative (This impact is unlikely to be a significant risk)
Cumulative Potential	Low Negative	Low Negative

4.4 CUMULATIVE IMPACTS

The impacts on each of the above fishing sectors could be increased due to the combination of impacts from other projects that may take place during the same period. Cumulative impacts include past, present and future planned activities which result in change that is larger than the sum of all the impacts. Cumulative effects can occur when impacts are 1. additive (incremental); 2. interactive; 3. sequential or 4. synergistic and would include anthropogenic impacts (including fishing and hydrocarbon industries) as well as non-anthropogenic effects such as environmental variability and climate change[28].

In the Benguela region, it has been suggested that the seasonal movement of Longfin Tuna northwards from the west coast of South Africa into southern Namibia may be disrupted by the noise associated with an increasing number of seismic surveys. While the potential exists to disrupt the movement of Longfin Tuna in the Benguela, this disruption, if it occurs, would be localised spatially and temporarily and would be compounded by environmental variability. In Australia, no direct cause and effect in changes in movement or availability of Bluefin Tuna could be attributed to seismic surveys (Evans et al, 2018), with observed changes being attributed to inter-annual variability. Due to the dearth of information on the impacts of seismic noise on truly pelagic species links between changes in migration patterns and subsequent catches thus remains speculative. In addition to the above the following should also be considered to take account of catch variability and stock declines, which can be attributed to the following (Shomura et al 1995, Kuo-Wie Lan et al 2011, Lehodey et al 2006 and Punt et al 1996):

- Increasing fishing effort exacerbated by improved fish finding technology (vessel monitoring systems, use of sonar, sea surface temperature spatial mapping using satellite technology);
- Environmental variability such as cold and warm water events e.g. Benguela El Niño events have been shown to result in a change in the vertical distribution of tuna stocks within the water column, resulting in reduced catch rates;
- Migration and feeding patterns that change abundance levels annually and are linked to the environment; and
- Inconsistent or irregular catch reporting.

This said, there is the possible chance of an increase in disturbance and disruption to fisheries active in the area and pressure on local services and facilities should additional exploration and mining activities commence (by other applicants or existing exploration right holders) in a relatively short period. There are a number of reconnaissance permit application and EIA / Basic assessments being undertaken for proposed seismic surveys off the West Coast, although it is unlikely that all these will be undertaken as they are targeting similar areas in the Deep Water Orange Basin. Table 4.16 lists the applications for petroleum exploration in the Southern Benguela region (South African West Coast and southern Namibia) since 2007, indicating which of these have been undertaken. Applications for mineral prospecting rights are also shown. Concurrent activities such as other planned speculative or proprietary seismic surveys in the southern Benguela region could add to the cumulative impact on fisheries. Although it is unlikely that concurrent seismic surveys would be undertaken in the same area during the same survey window, the current report includes an assessment of the cumulative impact on fisheries during simultaneous operations of three regional seismic surveys off the west coast. Simultaneous survey operations would result in an increase in the extent and magnitude of the impact

[28] Refer to Augustyn et al. (2018) for a synopsis of climate change impacts on South African Fisheries.

on the large pelagic longline sector. The impact duration would remain unchanged[27]. Three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of MEDIUM NEGATIVE significance on the large pelagic longline sector and of LOW NEGATIVE significance on the tuna pole-line sector, both with and without the application of mitigation measures. Once completed there is not expected to be any residual impact.

[27] Seismic surveys are undertaken within a window period of December to May as specified by DMRE as part of the EMP conditions to mitigate the impacts on sensitive migration periods for cetaceans.

Table 4.16: Applications for petroleum exploration and mineral prospecting in the Southern Benguela region (South African West Coast and southern Namibia) since 2007, indicating which of these have been undertaken.

1242

5 CONCLUSIONS AND RECOMMENDATIONS

The potential impacts of the seismic survey programme on fisheries relate to 1) exclusion of fishing vessels from accessing fishing ground, 2) the impact on catch rates as a result of increased noise levels associated with the seismic survey operation, 3) accidental loss of equipment from the survey array and 4) accidental release of marine diesel at sea. Table 5.1 lists the overall significance of each of the identified project impacts before and after the implementation of mitigation measures listed in Table 5.2.

Under the Convention on the International Regulations for Preventing Collisions at Sea (COLREGS, 1972, Part A, Rule 10), a seismic survey vessel that is engaged in surveying is defined as a "vessel restricted in its ability to manoeuvre" which requires that power-driven and sailing vessels give way to a vessel restricted in her ability to manoeuvre. Furthermore, under the Marine Traffic Act, 1981 (No. 2 of 1981), a vessel used for the purpose of exploiting the seabed falls under the definition of an "offshore installation" and as such it is protected by a 500 m safety zone. It is an offence for an unauthorised vessel to enter the safety zone. In addition to a statutory 500 m safety zone, a seismic contractor would request a safe operational limit (that is greater than the 500 m safety zone) that it would like other vessels to stay beyond. Safety clearances for seismic surveys are usually 6 Nm ahead and astern and 2 Nm to either side of the survey vessel, resulting in an exclusion area of approximately 165 km² around the survey vessel. The temporary exclusion of fisheries from the safety zone may reduce access to fishing grounds, which in turn could potentially result in a loss of catch and/or displacement of fishing effort (direct negative impact). The safety zone would be implemented around the seismic vessel for the duration of the project, resulting in an immediate impact that would endure for the duration of the proposed survey (~70 days). The impact of exclusion from fishing ground was assessed on each fishing sector based on the type of gear used and the proximity of fishing areas relative to the Reconnaissance Permit area. With the implementation of the project controls and mitigation measures, the residual impact of the proposed survey is considered to be of LOW NEGATIVE significance to large pelagic longline and tuna pole-line sectors. There is no impact expected on the demersal trawl, midwater trawl, demersal longline, small pelagic purse-seine, linefish, west coast rock lobster, netfish and small-scale fishing sectors.

The impact on catch rates due to sound elevation levels was assessed and sensitivity/vulnerability differences amongst the targeted fish species identified for each sector. Sound generated during the proposed seismic survey is expected to be in the order of 255 dB re 1 µPa at 1 m at an operating frequency range of 5 – 300 Hz. This falls within the hearing range of most fish species. A sound transmission loss modelling study (SLR 2021) identified predicted zones of impact for fish species (amongst other marine fauna species of concern) based on relevant noise impact assessment criteria. The noise effects assessed included physiological effects (physical injury/permanent threshold shift (PTS) and temporary threshold shift (TTS)) and behavioural disturbance due to either immediate impact from single airgun pulses or cumulative effects of exposure to multiple airgun pulses over a period of 24 hours. Based on the current project description, sound levels for the seismic survey could notionally be expected to attenuate to below levels for behavioural disturbance at a distance of 4 km from the source. The spatial extent of the impact of sound (produced by the airgun array) on catch rates is expected to be regional, although localised at any one time. The impact is considered to be of immediate duration and reversible without additional time or cost. Based on the distance of fishing grounds from the Reconnaissance Permit area, only the large pelagic longline and tuna pole-line sectors are considered to be susceptible to the effects of elevated sound. With the implementation of the project controls and mitigation measures, the residual impact due to seismic noise is considered to be of LOW NEGATIVE significance. There is no impact expected on the demersal trawl, midwater trawl,

JR28

demersal longline, small pelagic purse-seine, linefish, west coast rock lobster, netfish and small-scale fishing sectors

The Reconnaissance Permit area is situated in the Orange Basin, offshore of the shelf break and offshore of grounds of importance for many of South Africa's commercial fishing sectors, as well as small-scale and recreational fisheries. The large pelagic longline sector operates across the extent of the Reconnaissance Permit area, with activity focussed along the continental shelf break. The Application Area does not overlap key spawning or nursery areas therefore the risk of noise disturbance to spawning behaviour and fishery recruitment is considered unlikely.

This report has been compiled in accordance with the EIA Regulations, 2014 (Government Notice (GN) R982), as amended. It is the reasoned opinion of the specialist that the reconnaissance activities may be authorised, subject to the implementation of the mitigation measures proposed in Table 5.1.

In order to mitigate the impacts on the large pelagic longline sector, it is recommended that the survey avoid taking place during June and July. Prior to the commencement of survey activities, affected parties should be informed of the navigational co-ordinates of the proposed survey acquisition area, timing and duration of proposed activities and any implications relating to the safety zone that would be requested, as well as the movements of support vessels related to the project. The relevant fishing associations include FishSA, SA Tuna Association, SA Tuna Longline Association and Fresh Tuna Exporters Association.

Other key stakeholders should be notified prior to commencement and on completion of the project. These include; DFFE, the South African Navy Hydrographic Office (SANHO), South African Maritime Safety Association (SAMSA) and Ports Authorities.

For the duration of the survey, a navigational warning should be broadcast to all vessels via Navigational Telex (Navtext) and Cape Town radio. In addition, it is recommended that updates of the scheduled weekly survey plan should be circulated to the operators of affected fishing vessels on a daily basis. A Fisheries Liaison Officer (FLO) should be present on board the seismic vessel or escort vessel for the duration of the survey in order to facilitate communications between the seismic and fishing vessels in the project area.

Table 5.1 Recommended Mitigation Measures for Fisheries.

No.	Mitigation measure: Fisheries Exclusion
1	Avoid operating during June and July, in order to avoid periods of peak fishing effort by the large pelagic longline sector within the Reconnaissance Permit area.
2a	Prior to the commencement of seismic survey activities the following key stakeholders should be consulted and informed of the proposed seismic survey programme (including navigational co-ordinates of location, timing and duration of proposed activities) and the likely implications thereof (specifically the exclusion and safety zone around the seismic vessel):
	Fishing industry associations: SA Tuna Association; SA Tuna Longline Association and Fresh Tuna Exporters Association.
	Other key stakeholders: SAN Hydrographer, South African Maritime Safety Association, Ports Authority and the DFFE Vessel Monitoring, Control and Surveillance Unit in Cape Town.
	These stakeholders should again be notified at the completion of the project when the survey and support vessels are off location.
3	Request, in writing, the SAN Hydrographer to broadcast a navigational warning via Navigational Telex (Navtex) and Cape Town radio for the duration of the seismic survey activity.
4	Distribute a Notice to Mariners prior to the commencement of the seismic survey operations. The Notice to Mariners should give notice of (1) the co-ordinates of the survey area, (2) an indication of the proposed survey timeframes, (3) the dimensions of the towed gear array and dimensions of the safety zone around the seismic

	vessel, and (4) provide details on the movements of support vessels servicing the project. This Notice to Mariners should be distributed timeously to fishing companies and directly onto vessels where possible.
	An experienced Fisheries Liaison Officer (FLO) should be placed on board the seismic or guard vessel to facilitate communications with fishing vessels in the vicinity of the seismic survey areas
	The lighting on the seismic and support vessels should be managed to ensure that they are sufficiently illuminated to be visible to fishing vessels, as well as ensure that it is reduced to a minimum compatible with safe operations.
	Notify any fishing vessels at a radar range of 12 nm from the seismic vessel via radio regarding the safety requirements around the seismic vessel
	Implement a grievance mechanism in case of disruption to fishing or navigation.

Table 5.2 continued Recommended Mitigation Measures for Fisheries.

No.	Mitigation measure: Underwater Noise
	Avoid operating during June and July, in order to avoid periods of peak fishing effort by the large pelagic longline sector.
	Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if during daylight hours it is confirmed visually by the MMO during the pre-shoot watch (60 minutes) that there are no shoaling large pelagic fish within 500 m of the seismic source.
	In the case of shoaling large pelagic fish being observed within the mitigation zone, delay the "soft-start" until animals are outside the 500 m mitigation zone Terminate seismic shooting on • Observation of slow swimming large pelagic fish (including whale sharks, basking sharks, and manta rays) within the 500 m mitigation zone. • Observation of any obvious mass mortalities of fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO to be as a direct result of the survey. For slow-swimming large pelagic fish, terminate shooting until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required).
No.	Mitigation measure: Accidental Oil Spills
	Ensure personnel are adequately trained in both accident prevention and immediate response, and resources are available on each vessel.
	Obtain permission from DFFE to use low toxicity dispersants. Use cautiously
	Ensure adequate resources are provided to collect and transport oiled birds to a cleaning station.
	Ensure offshore bunkering is not undertake in the following circumstances: • Wind force and sea state conditions of ≥6 on the Beaufort Wind Scale; • During any workboat or mobilisation boat operations, • During helicopter operations; • During the transfer of in-sea equipment, and • At night or times of low visibility.
	Ensure that solid streamers rather than fluid-filled streamers are used. Alternatively, low toxicity fluid-fill streamers could be used
No.	Mitigation measure: Accidental Loss of Equipment to Sea
1	Ensuring that loads are lifted using the correct lifting procedure and within the maximum lifting capacity of the crane system.

Minimise the lifting path between vessels.

Undertake frequent checks to ensure items and equipment are stored and secured safely on board each vessel

Retrieval of lost objects / equipment, where practicable, after assessing the safety and metocean conditions. Establish a hazards database listing the type of gear left on the seabed and / or in the survey area with the dates of abandonment / loss and locations and, where applicable, the dates of retrieval

Notify SANHO of any hazards left on the seabed or floating in the water column, and request that they send out a Notice to Mariners with this information.

APPENDIX 1: ASSESSMENT CONVENTIONS

The EIA Team has adopted a set of conventions for purposes of the integrated assessment of potential impacts, and the determination of impact significance. The impact significance rating methodology, as provided by EIMS, is guided by the requirements of the NEMA EIA Regulations, 2014. The broad approach to the significance rating methodology is to determine the environmental risk (ER) by considering the consequence (C) of each impact (comprising Nature, Extent, Duration, Magnitude, and Reversibility) and relate this to the probability/ likelihood (P) of the impact occurring. This determines the environmental risk. In addition other factors, including cumulative impacts, public concern, and potential for irreplaceable loss of resources, are used to determine a prioritisation factor (PF) which is applied to the ER to determine the overall significance (S).

The significance (S) of an impact is determined by applying a prioritisation factor (PF) to the environmental risk (ER). The environmental risk is dependent on the consequence (C) of the particular impact and the probability (P) of the impact occurring. Consequence is determined through the consideration of the Nature (N), Extent (E), Duration (D), Magnitude (M), and reversibility (R) applicable to the specific impact.

For the purpose of this methodology the consequence of the impact is represented by:

$$C = \frac{(E + D + M + R) * N}{4}$$

Each individual aspect in the determination of the consequence is represented by a rating scale as defined in Table 17.

Table 17: Criteria for determination of impact consequence

Aspect	Score	Definition
Nature	-1	Likely to result in a negative/ detrimental impact
	+1	Likely to result in a positive/ beneficial impact
Extent	1	Activity (i.e. limited to the area applicable to the specific activity)
	2	Site (i.e. within the development property boundary),
	3	Local (i.e. the area within 5 km of the site),
	4	Regional (i.e. extends between 5 and 50 km from the site
	5	Provincial / National (i.e. extends beyond 50 km from the site)
Duration	1	Immediate (<1 year)
	2	Short term (1-5 years),
	3	Medium term (6-15 years),
	4	Long term (the impact will cease after the operational life span of the project),
	5	Permanent (no mitigation measure of natural process will reduce the impact after construction).
Magnitude/ Intensity	1	Minor (where the impact affects the environment in such a way that natural, cultural and social functions and processes are not affected),

	2	Low (where the impact affects the environment in such a way that natural, cultural and social functions and processes are slightly affected).
	3	Moderate (where the affected environment is altered but natural, cultural and social functions and processes continue albeit in a modified way).
	4	High (where natural, cultural or social functions or processes are altered to the extent that it will temporarily cease), or
	5	Very high / don't know (where natural, cultural or social functions or processes are altered to the extent that it will permanently cease).
Reversibility	1	Impact is reversible without any time and cost.
	2	Impact is reversible without incurring significant time and cost.
	3	Impact is reversible only by incurring significant time and cost.
	4	Impact is reversible only by incurring prohibitively high time and cost.
	5	Irreversible impact

Once the C has been determined the ER is determined in accordance with the standard risk assessment relationship by multiplying the C and the P. Probability is rated/scored as per

Table 18.

Table 18: Probability scoring

Probability	1	Improbable (the possibility of the impact materialising is very low as a result of design, historic experience, or implementation of adequate corrective actions; <25%),
	2	Low probability (there is a possibility that the impact will occur; >25% and <50%),
	3	Medium probability (the impact may occur; >50% and <75%),
	4	High probability (it is most likely that the impact will occur- > 75% probability), or
	5	Definite (the impact will occur),

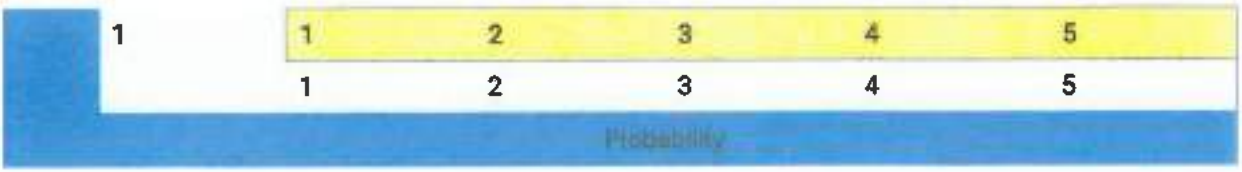
The result is a qualitative representation of relative ER associated with the impact. ER is therefore calculated as follows:

$$ER = C \times P$$

Table 19: Determination of environmental risk

Consequence	5	5	10	15	[illegible]	[illegible]
	4	4	8	12	16	[illegible]
	3	3	6	9	12	15
	2	2	4	6	8	10

1208



The outcome of the environmental risk assessment will result in a range of scores, ranging from 1 through to 25. These ER scores are then grouped into respective classes as described in Table 20.

Table 20: Significance classes

Risk Score	Description
< 10	Low (i.e. where this impact is unlikely to be a significant environmental risk).
≥ 10; < 20	Medium (i.e. where the impact could have a significant environmental risk).
≥ 20	High (i.e. where the impact will have a significant environmental risk).

The impact ER will be determined for each impact without relevant management and mitigation measures (pre-mitigation), as well as post implementation of relevant management and mitigation measures (post-mitigation). This allows for a prediction in the degree to which the impact can be managed/ mitigated.

Further to the assessment criteria presented above it is necessary to assess each potentially significant impact in terms of:

- Cumulative impacts; and
- The degree to which the impact may cause irreplaceable loss of resources.

To ensure that these factors are considered, an impact prioritisation factor (PF) will be applied to each impact ER (post-mitigation). This prioritisation factor does not aim to detract from the risk ratings but rather to focus the attention of the decision-making authority on the higher priority / significance issues and impacts. The PF will be applied to the ER score based on the assumption that relevant suggested management/ mitigation impacts are implemented.

Table 21: Criteria for the determination of prioritisation

Cumulative impact (CI)	Low (1)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is unlikely that the impact will result in spatial and temporal cumulative change.
	Medium (2)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is probable that the impact will result in spatial and temporal cumulative change.
	High (3)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/definite that the impact will result in spatial and temporal cumulative change.
Irreplaceable loss of resources (LR)	Low (1)	Where the impact is unlikely to result in irreplaceable loss of resources.
	Medium (2)	Where the impact may result in the irreplaceable loss (cannot be replaced or substituted) of resources but the value (services and/or functions) of these resources is limited.

	High (3)	Where the impact may result in the irreplaceable loss of resources of high value (services and/or functions).

The value for the final impact priority is represented as a single consolidated priority, determined as the sum of each individual criteria represented in

Table 21. The impact priority is therefore determined as follows:

$$Priority = CI + LR$$

The result is a priority score which ranges from 3 to 9 and a consequent PF ranging from 1 to 1.5 (refer to Table 22).

Table 22: Determination of prioritisation factor

Priority	Prioritisation Factor
2	1
3	1.125
4	1.25
5	1.375
6	1.5

In order to determine the final impact significance the PF is multiplied by the ER of the post mitigation scoring. The ultimate aim of the PF is to be able to increase the post mitigation environmental risk rating by a factor of 0.5, if all the priority attributes are high (i.e. if an impact comes out with a medium environmental risk after the conventional impact rating, but there is significant cumulative impact potential and significant potential for irreplaceable loss of resources, then the net result would be to upscale the impact to a high significance).

Table 23: Environmental Significance Rating

Value	Description
< -10	Low negative (i.e. where this impact would not have a direct influence on the decision to develop in the area).
≥ -10 < -20	Medium negative (i.e. where the impact could influence the decision to develop in the area).
≤ -20	High negative (i.e. where the impact would have an influence on the decision not to develop in the area).
0	No impact
< 10	Low positive (i.e. where this impact would not have a direct influence on the decision to develop in the area).
≥ 10 < 20	Medium positive (i.e. where the impact could influence the decision to develop in the area).

FF 28

Value	Description
≥ 20	High positive (i.e. where the impact must have an influence on the decision process to develop in the area)

The significance ratings and additional considerations applied to each impact will be used to provide a quantitative comparative assessment of the alternatives being considered. In addition, professional expertise and opinion of the specialists and the environmental consultants will be applied to provide a qualitative comparison of the alternatives under consideration. This process will identify the best alternative for the proposed project.

APPENDIX 2: CURRICULUM VITAE

SARAH WILKINSON SACNASP-Registered Professional Natural Scientist (Membership number 115656)

Geographical information systems, mapping and data analysis of southern African fisheries

Date of Birth: 20 June 1979

Nationality: South African / British

Academic Record: University of Cape Town, South Africa; BSc Honours (2001)
University of Cape Town; BSc (Oceanography and Botany 1998 – 2000)

Employment Record: Capricorn Marine Environmental (Pty) Ltd (2003 – 2019)
Institute of Plant Conservation, University of Cape Town (2002)

Languages: English (First language); Afrikaans & French (Basic written & spoken)

Key Experience:

- Geographical information systems, mapping and data analysis with focus on fisheries, oil and gas specialist assessments.
- Specialist assessments on the impact of offshore hydrocarbon exploration and installation activities on fisheries in South Africa, Namibia, Mozambique and Angola (in accordance with scoping and EIA requirements). **A selection of projects over the last five years is listed overleaf and a full list of project reports is available on request.**
- Management of Marine Mammal Observer (MMO), Passive Acoustic Monitoring (PAM) and Fisheries Liaison Services for seismic survey vessels in the offshore sub-Saharan region (a full list of over 100 deployments is available on request).
- Management of the industry-funded ship-based scientific observer programmes for the South African Pelagic Fishing Industry Association (SAPFIA) and the SA Deepsea Trawling Industry Association (SADSTIA).
- GIS support and analysis of the South African fishery catch and effort for use in the Offshore Marine Protected Area Project - contracted by the South African National Biodiversity Institute (SANBI).
- A review on the effects of trawling on benthic habitat in part fulfilment of the Marine Stewardship Council certification of the South African hake trawl fishery (Client: South African Deepsea Trawling Industry Association (SADSTIA).
- Spatial mapping of the proposed expanded Saldanha Bay Aquaculture Development Zone (ADZ) in line with the goals of operation Phakisa.
- Offshore Marine Protected Areas Project: spatial distribution/ mapping of South Africa's commercial fisheries for the South African National Biodiversity Institute
- Hake longline sector footprint. Spatial distribution of fishing effort and overlap with benthic habitats of the South African Exclusive Economic Zone (2002 – 2012) for WWF South Africa
- "Ringfencing the trawl footprint":- Desktop study for the South African Deepsea Trawling Industry Association

A complete list of Fisheries Impact Assessment Reports and Environmental Monitoring Close-Out Reports is available on request.

LK Mining	Marine Mining	EPL5965	May 2016
Murphy Lüderitz Oil Co. Ltd	Well Drilling	2613A & 2613B	Jul 2015
Xaris Energy Namibia	Subsea Pipeline Installation	Walvis Bay	Jul 2015
Nabinm Energy Services (Pty) Ltd	Seismic Survey	2113A	Jan 2015
Namdeb	Mapping of benthic habitat types, Southern Namibia inshore and nearshore region		

Courses and Symposia :

- 7th and 5th International Symposia on GIS/Spatial Analyses in Fishery and Aquatic Sciences, Hakodate, Japan & Wellington, New Zealand. International Fishery GIS Society

- Joint Nature Conservation Committee-certified Marine Mammal Observer Training (Intelligent Ocean Training Services)
- Passive Acoustic Monitoring Training (Intelligent Ocean Training and Consultancy Services and Seiche Measurements Ltd)
- Bureau of Ocean Energy Management, Regulation and Enforcement Gulf of Mexico: Protected Species Observer Training
- ArcGIS I, II and Spatial Analyst (GIMS: ESRI South Africa)
- Maxsea Navigational Software (TimeZero)
- Marine Stewardship Council Chain of Custody Training Course (Moody Marine Ltd)
- SAQA-approved learning facilitator

DAVID WILLIAM JAPP	SACNASP-Registered Professional Natural Scientist (Membership number 400208/12)
Date and Place of birth	Kabwe, Zambia 30 June 1956
Nationality	South African
Businesses Address	Unit 15 Foregate Square, Table Bay Boulevard, Cape Town, South Africa P.O. Box 50035, Waterfront, Cape Town 8002 Tel. +27 (21) 425 2161

Education:

Institution (Date from - Date to)	Degree(s) or Diploma(s) obtained:
Merchant Navy Academy General Botha, Cape Town (1975 to 1980)	Chief Navigating Officer (Foreign) – July 1980 to 1983
University of Cape Town (undergraduate) 1983 to 1985	Bachelor of Science (Zoology, Marine Biology and Oceanography)
Rhodes University 1986-1986	Bachelor of Science Honours Ichthyology and Fisheries Science (Cum Laude)
Rhodes University 1987 to 1989 and Sea Fisheries Research Institute	Masters Degree in Ichthyology and Fisheries Science (Cum Laude)
Rhodes University MBA 2006	Resource Economics

Key Experience Project Management and Appraisal
Environmental Impact Assessments (marine)
Marine Stewardship Council (MSC) assessor

Relevant Professional Experience (selected)

- South Africa: Head of Offshore Research - Sea Fisheries Research Institute (SFRI / DAFF) undertook 8 years of direct research and training of sea staff on biomass surveys as Chief Scientist;
- Consultant has worked extensively in the region including South Africa, Mozambique, Angola, Mozambique, Uganda, Namibia, Kenya, Tanzania and West Indian Ocean Fisheries Sectors since 1990;
- Benguela System : Benguela Current Commission (BCC) Strategic Impact Assessment (SEA)
- World Bank fisheries consultant – development and implementation of fisheries and aquaculture components - 1) MACEMP (Tanzania); 2) KCDP (Kenya) 3) SWIOFP (West Indian Ocean) 4) SWIOFish 1 (Current – WIO countries focus is Tanzania 5) LVEMP 2 (Lake Victoria)
- Environmental Impact Assessment of the Aquaculture Development Zone in Mossel Bay (South Africa)
- Scoping assessment and EIA of the potential for and Aquaculture Development Zone in Saldanha Bay, South Africa (pending)
- Lake Victoria – field trip and overview of the 'Source of the Nile' tilapia cage culture including provision of juvenile grow out and adult cage culture (conducted through LVEMP2 and the World Bank with the Lake Victoria Fisheries Organization and NAFIRI)

Date	Location	Company& reference person	Position	Description
Regional and International Experience				
1987 to 1996	South Africa	Sea Fisheries Research Institute and Marine and Coastal Management (Ref. Dr Augustyn)	Head of Offshore Research	Fisheries Research head – Management of Offshore resources including Demersal, Large Pelagic and Small Pelagic resources. Ref. is Dr J. Augustyn (Dept Agriculture, Forestry and Fisheries. Cape Town. (johann@seafstile.co.za)
1996 to 2016	Cape Town South Africa	Capricorn Fisheries Monitoring and Fisheries & Oceanographic Support Services	Consultant and Director	Many consulting projects with the FAO, World Bank, Benguela Current LME. Also developed the Regional Observers Programme. Specialization : Fisheries Management and Research ref. Xavier Vincent : xvincent@worldbank.org
2008 - 2009	Namibia	Benguela Current Commission	Consultant	State of Stock review – Benguela Current Commission. Hashali Hamukuaya hashali@benguelacc.org)
2009 to 2016 (ongoing)	Mombasa - Kenya)	Development of the Kenya Coastal Development Project (KCDP) – World Bank and FAO	Fisheries Expert	Thus was an ongoing consultancy (5 years) developing the KCDP with the World Bank Team – project participation was on near continuous basis until project effectiveness in June 2011. Portfolio : Fisheries Management, Research and Development : Ref is AG. Glauber - World Bank Office, Dar Es Salaam aglauber@worldbank.org
2007 to 2012	Tanzania and Zanzibar	Appraisal of the Tanzania *Marine and Coastal Environment Project* (MACEMP) - World Bank / FAO	Fisheries Expert	Ongoing consultancy every six months to Tanzania – Project appraisal and Mid-Term review. Presently project is winding down and new MACEMP two phase being developed. Portfolio : Fisheries Management, Research and Development : Ref is AG. Glauber - World Bank Office, Dar Es Salaam aglauber@worldbank.org
2006 to 2016	Kenya, Tanzania, Mozambique and IOC countries	World Bank and FAO – Fisheries Expert. Project development and implementation (South West Indian Ocean Fisheries Shared Growth and Governance Project (SWIOFish 1)	Fisheries Expert	Consultancy up to 2015 – fisheries components – development and implementation. Specialization : Fisheries Management and Development. Ref ; AJ Glauber aglauber@worldbank.org
2004 to 2007	IOTC	IOTC	Fisheries Experts	Provision of trained tuna tagging technicians and Cruise leaders for the IOTC Tuna Tagging programme (Note: this was done through CapFish under contract to MEP). Ref : Gerard Dominique (IOTC) . gerard.dominique@iotc.org
2009 to ongoing	IOTC	IOTC	Fisheries Observers	Provision of Observers for Transhipment vessels (ongoing) Gerard Dominique (IOTC) gerard.dominique@iotc.org

2004 to 2014	FAO	FAO – Jessica Sanders / Ross Shotton	Fisheries Expert	Consultancy undertaken for technical works relating to 1. South West Indian Ocean Fisheries 2. Regional (Indian Ocean) fisheries reporting (catches) 3. Observer training (Madagascar) 4. Development of High Sea Guidelines (FAO)
2009 to 2016	FAO and WWF	FAO - and WWF USA	Fisheries Expert	Fishery Improvement Process – fishery pre-assessments for MSC and follow-up. Contract is current. Portfolio : Fisheries Management and Development. Domingos Gove (dgove@wwfesampo.org
2013	Angola Namibia (BCC)	ACP Fish 2	Fisheries Expert	Development of horse mackerel national plans and transboundary management (BCC)
2004-current	International	MSC Assessments – RSA Hake, Tristan da Cunha lobster, Russian Pollock and numerous pre-assessments and peer rev.	Fisheries expert : P2 and P3	Full assessments through CABs (Moody, Intertek, MRAG, Tavel, FCI, BV, Acroura)

ADDITIONAL INFORMATION

Major Projects - Summary

- Resource Assessment
- Submission of management advice on hake (TAC assessments from 1989 to 1997);
- Biological assessment of hake species in South African waters and determination of ageing and stock structure,
- Design of hake-directed biomass surveys and cruise leader on up to four demersal surveys a year from 1989 to 1997;
- Demersal Working Group co-ordinator from 1991 to 1997 responsible for the management advice on hake and other demersal species;
- Project management (Scientist responsible) of hake-directed longline experiment in SA from 1992-1996

Aquaculture-Specific

- Post graduate degrees in Fisheries science included bot fresh water and marine aquaculture
- East African project undertaken with the World Bank include major fisheries components which incorporate development of aquaculture (fresh and marine)
- Scoping studies and impact assessments of Aquaculture Development Zones in Mossel Bay (South Africa)
- Scoping studies and EIA of ADZ in Saldanha Bay (this project is not yet activated and is pending subject to tender and financing)
- World Bank Project (LVEMP2) – consultant has been providing specialist fisheries advice to the LVFO including aquaculture field work in the Jinga / Lake Victoria including the use of Mukene as both feed and for human consumption
- Assessment of the Saldanha Bay Aquaculture Development Zone (ADZ – current)

Fishery Economics and Governance :

- Preparation of sector economic reports for RSA fisheries to assist with rights allocation procedures: Hake Longline, Inshore Trawl (Hake and Sole), Shark longline, South Coast Rock Lobster, Patagonian Toothfish, Deepwater Fishery, Midwater Trawl & Hake Handline

- Economic Assessment of the Westfish and Freezer Trawl apportionment of Hake in Namibia
- BCLME – Ecosystem Approach to Fisheries – Cost Benefit Analysis (March 2006)
- Review of the West Indian Ocean Tuna Fishery and Potential Opportunities and Options for the Development of the Port of Victoria (Seychelles) – Completed March 2008
- Assessment of economic loss due to hydrocarbon development – numerous ongoing projects, PetroSA, Forrest Oil west coast gas, CNR well drilling and many others.
- Value-Adding of Anchovy *Engraulis encrasicolus* in South Africa and potential for poverty relief.
- Governance of Kenya Fisheries – Consultancy and report prepared for IOC Smartfish programme (2011)

Other Projects Completed :

- Comparative assessment (socio-economic) of trawl and Longline fisheries in Benguela Region (BCLME).
- Evaluation of deepwater groundfish fishery in South West Indian Ocean 2004/2005 – FAO.
- Review of Ecosystem Approach to Fisheries Management for South African Fisheries (BCLME – MCM project).
- Review of South Africa's Indian Ocean fisheries – management and policy.
- Development of the South West Indian Ocean Fisheries Programme Implementation Plan – World Bank / FAO – Completed March 2007 (preparation of Project Documents for World Bank and GEF).
- Ecosystem Approach to Fisheries – BCLME project LMR/EAF/03/01 – Contracted consultant including Risk Assessments and Benefit Cost estimators for EAF – Ongoing as of 5 November 2006.
- Indian Ocean Tuna Tagging Programme – 2004-2007 collaborative programme with McAllister Elliot and Partners (UK) and Capricorn Fisheries Monitoring cc (RSA)
- Indian Ocean Tuna Commission – 2009 Collaborative programme between MRAG (UK) and Capricorn Fisheries Monitoring cc for the provision of Observers and monitors on Indian Ocean tuna transhipment vessels.
- International Commission for the Conservation of Atlantic Tunas – 2007 Collaborative programme between MRAG (UK) and Capricorn Fisheries Monitoring cc for the provision of Observers and monitors on Atlantic tuna transhipment vessels.
- Domestic contract awarded (Sept. 2007) for the monitoring of national and high seas tuna longline fisheries, all trawl and small pelagic sectors and deep water rock lobster trap fisheries
- FAO / World Bank – review of Tanzania MACEMP programme with WB surveillance team (2008, 2009, 2010, 2011, 2012)
- FAO / World Bank – initiation of the South West Indian Ocean Fisheries Project – development of Project Implementation Manual and Observer programme (Mombasa – 2007- 2009)
- FAO / World Bank – Project development – Kenya Coastal Development Project (KCDP) – Ongoing 2010-2015
- FAO – EAF-Nansen Programme – Mozambique Sofala Bank Shrimp fishery management plan – development of effort management recommendations.
- FAO World Bank – Lake Victoria LVEMP project. Project management and support to Lake Victoria Fisheries Organisation.
- FAO World Bank – South West Indian Ocean Fisheries Shared Growth and Governance Project (Tanzania effective from June 2015)
- ICCAT Tuna Transhipment Programme Observers – CapFish project executant (2009 to 2012) – ongoing
- IOTC Tuna Transhipment Programme Observers – CapFish project executant (2010-2012) – ongoing
- Tuna Longline – RSA Observer deployments – 100% coverage on Deep Water Fishing Nations (RSA) – Project executant (2007-2012) – on-going
- IOTC Tuna – review of economic reports undertaken by WWF (10 country reports and summaries) – May 2012

Marine Stewardship Council :

- Numerous fisheries assessed including Russian Pollock, Tristan da Cunha Lobster, RSA Hake and many others including many pre-assessments
- Fishery improvement projects ongoing : Kenya Lobster, Mozambique shallow and deepwater shrimp and Namibian Hake assessment
- Assessment of the PNA Western Pacific tuna Fishery (current September 2016)

- Review of the Mozambique linefish fishery (MSC preassessment) and SASSI assessment (WWF - South Africa) (Current September 2016)

Lecturing and Document Preparation:

- Extensive lecturing and seminar presentations (30 years) as well as detailed project and document preparation experience.
- Presentation of 5 x International courses in Namibia on International Agreements, UNCLOS, RFO's etc to Inspectors, Observers and Fisheries Managers.

DECLARATION OF THE ENVIRONMENTAL SPECIALIST

I, SARAH JANE WILKINSON (Full Name and Surname) declare that –

General declaration:

- I act as an independent specialist in this application.
- I will perform the work relating to the application in an objective manner, even if this results in views and findings that are not favorable to the applicant.
- I declare that there are no circumstances that may compromise my objectivity in performing such work.
- I have expertise in conducting undertaking the specialist work as required, including knowledge of the Act, Regulations and any guidelines that have relevance to the proposed activity.
- I will comply with the Act, Regulations, and all other applicable legislation.
- I have not, and will not engage in, conflicting interest in the undertaking of the activity.
- I understand to disclose to the applicant and competent authority all material information in my possession that reasonably has or may have the potential of influencing- any decision to be taken with respect to the application by the competent authority; and the objectivity of any report, plan or document to be prepared by myself for submission to the competent authority.
- I have taken into account, to the extent possible, the matters referred to in Regulation 18 when preparing the report, plan or document.
- I will provide the competent authority with access to all information at my disposal regarding the application, whether such information is favorable to the applicant or not.
- All the particulars furnished by me this form are true and correct.
- I will perform all other obligations as expected from an environmental assessment practitioner in terms of the Regulations.
- I am aware of what constitutes an offence in terms of Regulation 48 and that a person convicted of an offence in terms of Regulation 48(1) is liable to the penalties as contemplated in Section 49B of the Act.

Disclosure of Vested Interest (delete whichever is not applicable)

I do not have and will not have any vested interest (either business, financial, personal or other) in the proposed activity proceeding other than remunerative for work performed in terms of the Regulations.

REVISION HISTORY

Version	Issue Date	Description of Changes
001	28 September 2022	First draft

Declaration of Independence

- I, Wouter Fourie, declare that –
- General declaration:
- I act as the independent heritage practitioner in this application
- I will perform the work relating to the application in an objective manner, even if this results in views and findings that are not favourable to the applicant
- I declare that there are no circumstances that may compromise my objectivity in performing such work;
- I have expertise in conducting heritage impact assessments, including knowledge of the Act, Regulations and any guidelines that have relevance to the proposed activity;
- I will comply with the Act, Regulations and all other applicable legislation;
- I will take into account, to the extent possible, the matters listed in section 38 of the NHRA when preparing the application and any report relating to the application;
- I have no, and will not engage in, conflicting interests in the undertaking of the activity;
- I undertake to disclose to the applicant and the competent authority all material information in my possession that reasonably has or may have the potential of influencing - any decision to be taken with respect to the application by the competent authority; and - the objectivity of any report, plan or document to be prepared by myself for submission to the competent authority;
- I will ensure that information containing all relevant facts in respect of the application is distributed or made available to interested and affected parties and the public and that participation by interested and affected parties is facilitated in such a manner that all interested and affected parties will be provided with a reasonable opportunity to participate and to provide comments on documents that are produced to support the application;
- I will provide the competent authority with access to all information at my disposal regarding the application, whether such information is favourable to the applicant or not
- All the particulars furnished by me in this form are true and correct;
- I will perform all other obligations as expected from a heritage practitioner in terms of the Act and the constitutions of my affiliated professional bodies; and
- I realise that a false declaration is an offence in terms of regulation 71 of the Regulations and is punishable in terms of section 24F of the NEMA.

Disclosure of Vested Interest

- I do not have and will not have any vested interest (either business, financial, personal or other) in the proposed activity proceeding other than remuneration for work performed in terms of the Regulations;

EXECUTIVE SUMMARY

PGS Heritage (Pty) Ltd was appointed by Environmental Impact Management Services Consulting (Pty) Ltd (EIMS) on behalf of TGS Geophysical Company (UK) (TGS) to undertake a Heritage Impact Assessment (HIA) that forms part of the Basic Environmental Assessment (BA) for their proposed 3D seismic survey off the West Coast of South Africa. The application area is located between approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay, Off the West Coast, South Africa.

Site Name

TGS West Coast 3D Reconnaissance Project

Site Location

The proposed project is located offshore between approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay.

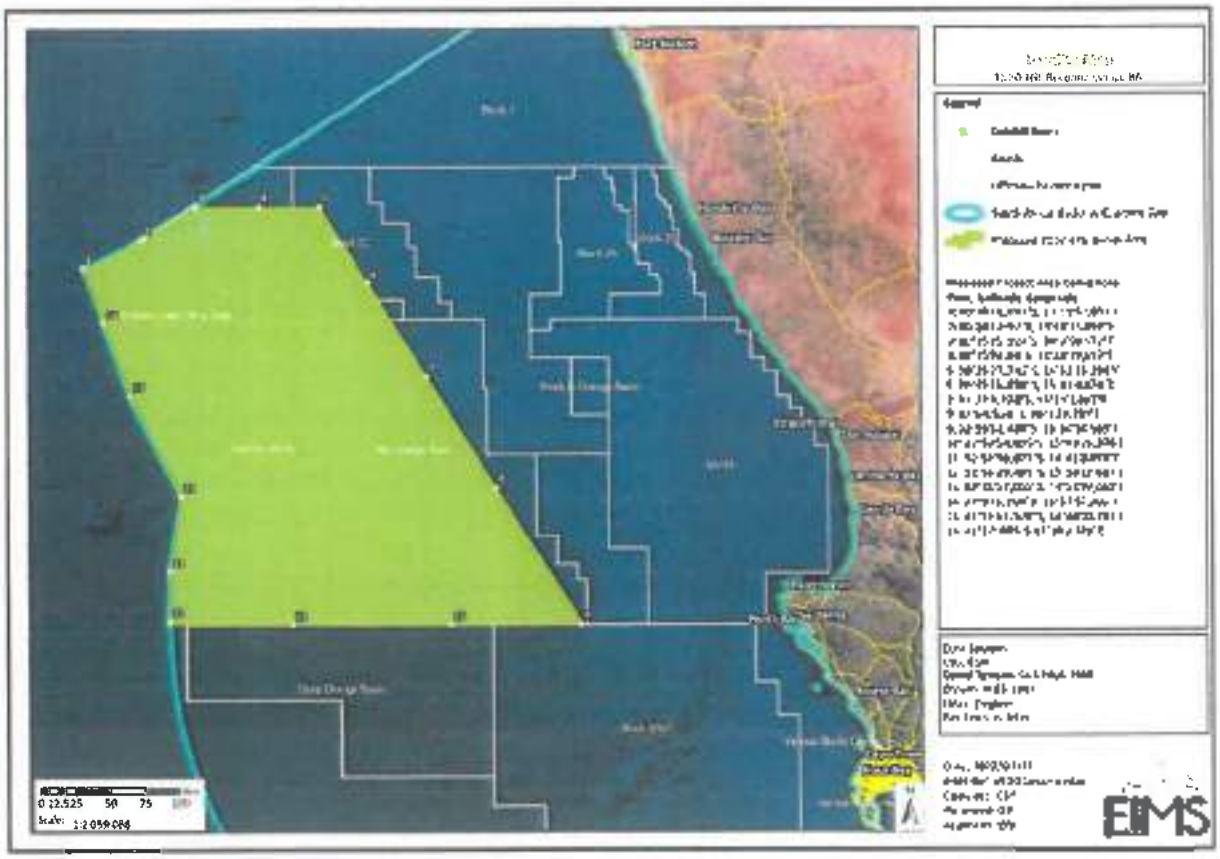

Figure 1 – Map indicating the location of the proposed survey project (green polygon) (source: EIMS).

Heritage Statement

It must be noted that, first and foremost, a large section of the affected communities not only view them as small-scale fishers but also as indigenous people and, as such, are intrinsically linked to the ocean and the land they have lived on for centuries. The resurgence movement through which Khoi and San descendants are reclaiming their identity has in recent decades afforded these communities the ability to re-establish their cultural roots and grounding in an ancient landscape. This sentiment is echoed in the founding affidavit submitted (5 Feb 2022) during the appeal submitted to the first Searcher application by CJ Adams. It notes that the ocean is not only important for fishing but also has spiritual meaning and is a place of healing and holds healing powers for the indigenous communities. It further expanded that the ocean and its resources play an important part in their community's history and heritage.

Community identity and culture are thus strongly linked to the ocean and what it can provide, physically and spiritually. Communities have coexisted with the ocean for generations. This existence has created a culture and heritage that defines their way of living, community, and kinship unique to the West Coast of South Africa. Cook (2001) describes this as maritimity, a process whereby the sum of cultural adaptations made by coastal populations becomes imbued with meaning and culture. This is evident in community structures, cultural events, and seasonal activities.

The public meetings and focused discussions with interlocutors have shown that these communities and groupings are struggling economically due to decades of turmoil in the fishing industry. An industry plagued by the closing of fish processing plants, fishing licence and quota issues, and diminishing catches due to environmental and industrial impacts, to name a few. This economic downturn leads to social issues within the communities. Foremost are poverty, loss of social fabric, substance abuse, teenage pregnancies, and violence. In all the interviews, the above issues were raised as central to their social existence and community experience.

As with Smith (2015), Loulanki (2006), and Ndoro (2105) emphasised that culture is more than just the tangible but is also shared beliefs, values, language, traditions, functionality, meaning and community connections. Considering the various values and heritage significance as listed in section 3(3) of the NHRA, the cultural and living heritage associated with the communities and indigenous people along the southwestern and west coast of South Africa holds heritage significance. It is part of the national estate and holds importance as a way of life for small-scale fishers and Khoisan descendants alike. The physical and spiritual interaction with the ocean and the shorelines through millennia resulted in a maritimity that developed into the cultural fabric as they experience it today.

The significance of such intangible and living cultural heritage features can potentially have a combined heritage grading of Grade II or even Grade I through further research. However, grading inevitably implies the investigation into and consideration of a Provincial or Heritage declaration of significance for a largely intangible cultural heritage. This is problematic as the NHRA provides for the proclamation/declaration of place, objects, or structures as Provincial or National Heritage Sites and only refers to intangible/living heritage relating to such place, objects, or structures.

Impact Statement

The scientific studies conducted for this project identified impacts on the fishing stock as low for all types of species.

By inference, a potential impact on fishing yield could be expected and thus potential economic impact on communities due to reduced caught fish volumes.

We considered that the recommended mitigation measures, as listed in the specialist reports for the project, focus on the reduction of impacts on fish species and the projected reduction of the impact on the commercial and small-scale fishery catch yield. These mitigation measures should then indirectly positively impact the potential negative impacts on the cultural heritage of the communities to be impacted.

By using the impact assessment methodology as provided by EIMS, we can project a pre-mitigation negative impact on a regional scale over the long term with a moderate intensity due to the potential indirect impact on the communities and, ultimately, their heritage, with a high probability of this impact occurring. The pre-mitigation impact on heritage resources is rated as MEDIUM. The potential residual impact on heritage resources, with mitigation measures from the scientific studies is projected as LOW with a medium confidence factor.

PGS is aware of the current Searcher application and the potential of another application soon occurring in the Orange Basin. Communities have expressed a definite concern about the multiple application occurring in their fishing waters and the potential long-term effect of these surveys resulting in Oil and Gas companies starting applications for production rights based on the findings of these reconnaissance surveys. ***It is, however, the understanding that only one 3D survey will be done in the overlapping areas even if the various applications are successful over the same area.***

At this stage, cumulative impacts are purely speculative. Still, the potential for the future increase in cumulative impacts due to current and future seismic surveys and the potential for future Oil and Gas production cannot be excluded but is not quantifiable at this stage for cultural heritage.

Recommendations

The following recommendations are based on the UNESCO ICH guidelines. They are aimed at safeguarding the cultural heritage of the small-scale fishers and cultural groupings in the influence of this project:

- Re-assess post-project the potential effects on the identified communities and their intangible cultural heritage. This will require consideration of the socio-economic baseline developed during this environmental impact process against quantified economic damage and losses and human development impacts in a follow-up socio-economic. It will enable the heritage specialist to evaluate the link between the socio-economic changes induced by the proposed project as it relates to changes in the intangible cultural heritage practices of the communities.

- Based on the outcomes, **provide resources and support for communities** to develop and undertake safeguarding measures or plans to enhance the **mitigation capacity of their intangible cultural heritage** by **fostering dialogue, mutual understanding and reconciliation** between and within communities. It is anticipated that this can be achieved through the implementation of the mitigation measures in the Social Impact Assessment.

We know that 3D seismic surveys can locate wrecks on the surface and sometimes below sediments. Any shipwrecks or pieces noted during the survey must be shared with the SAHRA MUCH Unit for inclusion in the national database. These could then be identified and incorporated into the EMP.

Considering the assessment based on the fieldwork findings and the scientific studies relating to the impact on fisheries, I am of the opinion that the impact of the proposed project on the intangible cultural heritage resources and practices can be mitigated through the implementation of the recommendations in this report.

TERMINOLOGY AND ABBREVIATIONS

Archaeological resources

This includes:

- material remains resulting from human activity which are in a state of disuse and are in or on land and which are older than 100 years including artefacts, human and hominid remains and artificial features and structures;
- rock art, being any form of painting, engraving or other graphic representation on a fixed rock surface or loose rock or stone, which was executed by human agency and which is older than 100 years, including any area within 10m of such representation;
- wrecks, being any vessel or aircraft, or any part thereof, which was wrecked in South Africa, whether on land, in the internal waters, the territorial waters or in the maritime culture zone of the republic as defined in the Maritimes Zones Act, and any cargo, debris or artefacts found or associated therewith, which is older than 60 years or which SAHRA considers to be worthy of conservation;
- features, structures, and artefacts associated with military history which are older than 75 years and the site on which they are found.

Cultural significance

This means aesthetic, architectural, historical, scientific, social, spiritual, linguistic, or technological value or significance

Development

This means any physical intervention, excavation, or action, other than those caused by natural forces, which may in the opinion of the heritage authority in any way result in a change to the nature, appearance or physical nature of a place or influence its stability and future well-being, including:

- construction, alteration, demolition, removal or change in use of a place or a structure at a place;
- carrying out any works on or over or under a place;
- subdivision or consolidation of land comprising a place, including the structures or airspace of a place;
- constructing or putting up for display signs or boards;
- any change to the natural or existing condition or topography of land; and
- any removal or destruction of trees, or removal of vegetation or topsoil

Early Stone Age

The archaeology of the Stone Age between 700 000 and 2 500 000 years ago.

Fossil

Mineralised bones of animals, shellfish, plants, and marine animals. A trace fossil is the track or footprint of a fossil animal that is preserved in stone or consolidated sediment.

Heritage

That which is inherited and forms part of the National Estate (historical places, objects, fossils as defined by the National Heritage Resources Act 25 of 1999).

Heritage resources

This means any place or object of cultural significance and can include (but not limited to) as stated under Section 3 of the NHRA,

- places, buildings, structures and equipment of cultural significance;
- places to which oral traditions are attached or which are associated with living heritage;
- historical settlements and townscapes;
- landscapes and natural features of cultural significance;
- geological sites of scientific or cultural importance;
- archaeological and palaeontological sites;
- graves and burial grounds, and
- sites of significance relating to the history of slavery in South Africa;

Holocene

The most recent geological period which commenced 10 000 years ago.

Late Stone Age

The archaeology of the last 30 000 years associated with fully modern people.

Late Iron Age (Early Farming Communities)

The archaeology of the last 1000 years up to the 1800's, associated with iron-working and farming activities such as herding and agriculture.

Middle Stone Age

The archaeology of the Stone Age between 30 000-300 000 years ago, associated with early modern humans.

Palaeontology

Any fossilised remains or fossil trace of animals or plants which lived in the geological past, other than fossil fuels or fossiliferous rock intended for industrial use, and any site which contains such fossilised remains or trace.

1 INTRODUCTION

PGS Heritage (Pty) Ltd was appointed by Environmental Impact Management Services Consulting (Pty) Ltd (EIMS) on behalf of S TGS Geophysical Company (UK) (TGS) to undertake a Heritage Impact Assessment (HIA) that forms part of the Basic Environmental Assessment (BA) for their proposed 3D seismic survey off the West Coast of South Africa. The application area is located between approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay, Off the West Coast, South Africa.

1.1 SCOPE OF THE STUDY

The aim of the study is to identify the heritage resources that may be impacted upon by the proposed project. The HIA aims to inform the BA to assist the developer in managing the discovered heritage resources in a responsible manner, to protect, preserve, and develop them within the framework provided by the National Heritage Resources Act of 1999 (Act 25 of 1999) (NHRA).

1.2 SPECIALIST QUALIFICATIONS

This HIA Report was compiled by PGS Heritage (PGS).

The staff at PGS has a combined experience of nearly 90 years in the heritage consulting industry. PGS and its staff have extensive experience in managing HIA processes. PGS will only undertake heritage assessment work where they have the relevant expertise and experience to undertake that work competently.

The following individuals were involved with this study:

- Wouter Fourie, the Project Coordinator and Principal Heritage Practitioner, is registered with the ASAPA as a Professional Archaeologist and is accredited as a Principal Investigator, he is further an Accredited Professional Heritage Practitioner with the Association of Professional Heritage Practitioners (APHP).

- Nikki Mann, the author of this report, is registered as a Professional Archaeologist with the Association of Southern African Professional Archaeologists (ASAPA). She has 4 years of experience in the heritage assessment field and holds a Master's degree (MSc) in Archaeology from the University of Cape Town.

1.3 ASSUMPTIONS AND LIMITATIONS

Not detracting from the stakeholder engagement completed, it is necessary to realise that the intangible heritage elements identified during engagements do not necessarily represent all

possible intangible cultural heritage elements present in this region. Various factors account for this, including the layered histories (e.g., memory of conflict, dispossession, and disempowerment through time) associated with the West Coast region, specifically in terms of intangible and living heritage resources associated with the ocean landscape. The values attributed to the ocean by the communities do not necessarily align to provide one definitive single significance to the ocean. Instead, the depth and complexity of values assigned to intangible heritage in this landscape depends on peoples' relationship to the ocean and their feelings about the proposed project.

1.4 LEGISLATIVE CONTEXT

The identification, evaluation and assessment of any cultural heritage site, artefact or find in the South African context is required and governed by the following legislation:

- Notice 648 of the Government Gazette 45421- general requirements for undertaking an initial site sensitivity verification where no specific assessment protocol has been identified
- National Environmental Management Act (NEMA), Act 107 of 1998 – Appendix 6
- National Heritage Resources Act (NHRA), Act 25 of 1999

1.4.1 NEMA – APPENDIX 6 REQUIREMENTS

The HIA report has been compiled considering the NEMA Appendix 6 requirements for specialist reports, as indicated in the table below. For ease of reference, the table below provides cross-references to the report sections where these requirements have been addressed.

1.4.2 THE NATIONAL HERITAGE RESOURCES ACT

- National Heritage Resources Act (NHRA) Act 25 of 1999
    - Protection of Heritage Resources – Sections 34 to 36; and
    - Heritage Resources Management – Section 38

The NHRA is utilised as the basis for the identification, evaluation, and management of heritage resources and in the case of Cultural Resource Management (CRM), those resources are specifically impacted by development as stipulated in Section 38 of NHRA. This study falls under s38(8) and requires comment from the relevant heritage resources authority.

2 TECHNICAL DETAILS OF THE PROJECT

The following background information is provided by EIMS.

2.1 LOCALITY

TGS proposes to undertake a 3D seismic survey off the West Coast of South Africa. The proposed project area approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay over several petroleum licence blocks

FL28

(Figure 3). The area of interest for the proposed 3D seismic survey is approximately 57 400 km2 in extent.

The survey area corner coordinate points are as follows:

Table 1 - Coordinates of the proposed survey area.

Point	Latitude	Longitude	Point	Latitude	Longitude
1	32°59'53.46"S	16°35'02.75"E	6	30°40'16.36"S	13°20'38.26"E
2	32°59'57.95"S	13°53'17.25"E	7	30°32'53.92"S	13°35'15.39"E
3	32°39'06.43"S	13°53'26.20"E	8	30°15'21.82"S	14°04'05.31"E
4	32°09'29.22"S	13°56'04.38"E	9	30°15'27.76"S	14°52'29.65"E
5	31°31'44.64"S	13°39'01.12"E			

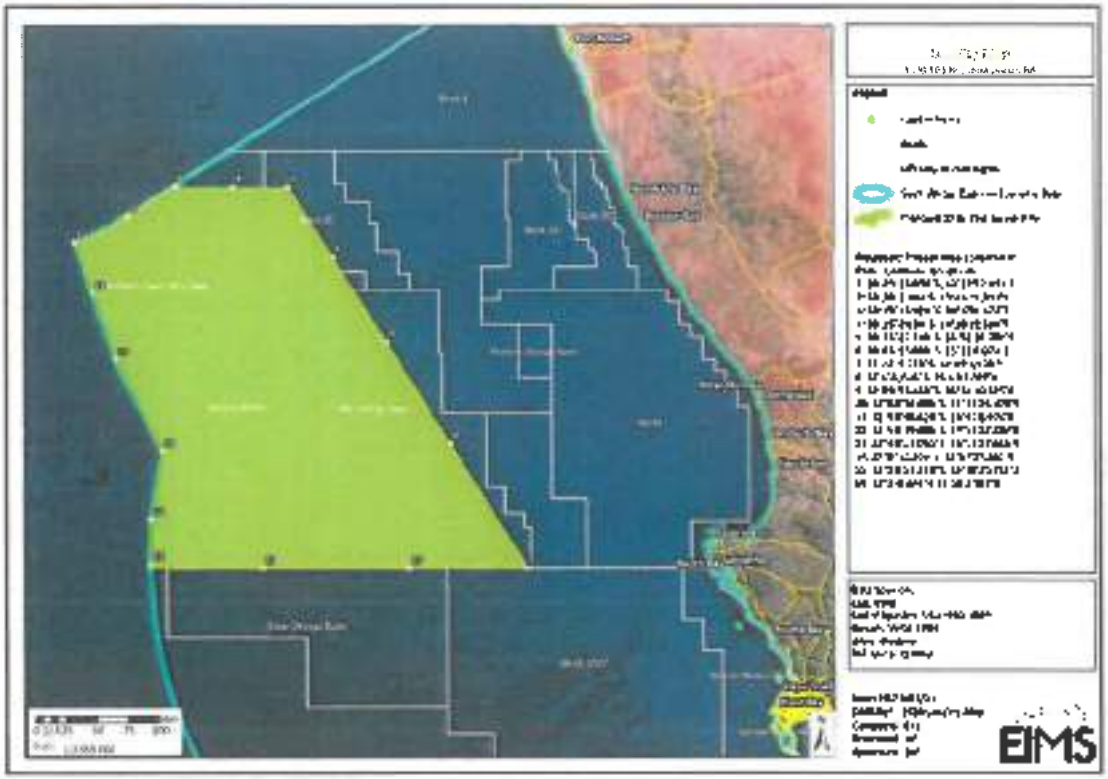

Figure 3 – Map indicating the location of the proposed survey project (green polygon) (source: EIMS).

2.2 TECHNICAL PROJECT DESCRIPTION

TGS is planning to conduct a seismic campaign over in the Orange Basin during the best available window of opportunity in either 2023 or 2024, subject to granting of the Reconnaissance Permit and vessel availability. The Reconnaissance Permit Area is approximately 57 400 km2 in extent. Water depths in the Reconnaissance Permit Area range from ~500 m to nearly 4 000 m. The area is situated roughly between the Orange River mouth and Cape Columbine, approximately 120 km offshore at its closest points. The total 3D survey duration would be in the order of up to four months.

The anticipated acoustic source (airgun) and hydrophone array would consist of 24 active guns with operating pressures of 2 000 pound-force per square inch (psi), situated some 50 m behind the vessel at a depth of 7 - 8 m below the surface. The 3D survey will involve multiple streamers (up to 12 streamers spaced 100 m apart) up to 12 000 m long, towed at a depth of approximately 8 m.

The seismic vessel would steam a series of predefined transects describing the survey grid, the headings of which would be fixed and reciprocal. During surveying the seismic vessel would travel at a speed of between four and six knots and the sound sources would be "fired" by the airgun array. As the seismic vessel would be restricted in manoeuvrability (a turn radius of approximately 5 km is expected), other vessels should remain clear of it. A support vessel usually assists in the operation of keeping other vessels at a safe distance.

Each triggering of a sound pulse is termed a seismic shot, and these are fired at intervals of 6 - 20 seconds (depending on water depth and other environmental characteristics) (Barger & Hamblen 1980). Each seismic shot is usually only between 5 and 30 milliseconds in duration, and despite peak levels within each shot being high, the total energy delivered into the water is low. Airguns have most of their energy in the 5-300 Hz frequency range, with the optimal frequency required for deep penetration seismic work being 50-80 Hz.

Sound levels from individual airguns use today in the seismic industry range from 200 to 232 dB re 1 µPa at 1 m, for small to large individual guns, respectively. For airgun arrays, sound levels range from 235 dB re 1 µPa at 1 m for a small array (500 cubic inches) to 260 dB re 1 µPa at 1 m for large arrays (7 900 cubic inches) (Bröcker 2019). The majority of the produced energy is below 250 Hz, with 90% of the energy between 70 to 140 Hz, although pulses do contain some higher frequencies up to 16 kHz (Bröcker 2019). It must be noted, however, that the sound level specifications for airgun arrays refer to sound levels in the vertical direction directly beneath the airgun array, generally near its centre, with nominal sound levels in the horizontal direction being ~10-20 dB lower (Caldwell & Dragoset 2000; Dragoset 2000).

3 ASSESSMENT METHODOLOGY

The section below outlines the assessment methodologies utilised in the study.

3.1 METHODOLOGY FOR ASSESSING HERITAGE SITE SIGNIFICANCE

This HIA report was compiled by PGS for the proposed project. The applicable maps, tables and figures are included, as stipulated in the NHRA (no 25 of 1999) and the National Environmental Management Act (NEMA) (No. 107 of 1998). The HIA process consists of three steps:

Step I – Literature Review and initial analysis: The background information to the field survey relies greatly on the Heritage Background Research undertaken for the study area.

Step II – The first phase of stakeholder engagement was part of the Public Participation process conducted by EIMS for the project. These public meetings were attended by a specialist from PGS to identify heritage themes highlighted by attendees to the meetings. Individuals and grouping were then identified to engage with in focussed meetings and interviews.

Step III – Focussed interviews with identified individuals and cultural group representatives. The aim was to build a database of tangible and intangible heritage that could potentially be impacted by the proposed project.

3.2 HERITAGE SIGNIFICANCE

Heritage significance classification standards use is based on the heritage classification of s3 in the NHRA and developed for implementation keeping in mind the grading system approved by SAHRA for archaeological impact assessments. The update classification and rating system as developed by Heritage Western Cape (2021) is implemented in this report

Site significance classification standards prescribed by the Heritage Western Cape Guideline (2016), were used for the purpose of this report (**Table 2** and **Table 3**).

Table 2 - Rating system for archaeological resources

Grading	Description of Resource	Examples of Possible Management Strategies	Heritage Significance
I	Heritage resources with qualities so exceptional that they are of special national significance. Current examples: Langebaanweg (West Coast Fossil Park) Cradle of Humankind	May be declared as a National Heritage Site managed by SAHRA. Specific mitigation and scientific investigation can be permitted in certain circumstances with sufficient motivation.	Highest Significance

Grading	Description of Resource	Examples of Possible Management Strategies	Heritage Significance
II	Heritage resources with special qualities which make them significant, but do not fulfil the criteria for Grade I status. Current examples: Blombos, Paternoster Midden.	May be declared as a Provincial Heritage Site managed by Provincial Heritage Authority. Specific mitigation and scientific investigation can be permitted in certain circumstances with sufficient motivation.	Exceptionally High Significance
III	Heritage resources that contribute to the environmental quality or cultural significance of a larger area and fulfils one of the criteria set out in section 3(3) of the Act but that does not fulfil the criteria for Grade II status. Grade III sites may be formally protected by placement on the Heritage Register.		
IIIA	Such a resource must be an excellent example of its kind or must be sufficiently rare. Current examples: Varschedrift; Peers Cave; Brobartia Road Midden at Betty's Bay	Resource must be retained. Specific mitigation and scientific investigation can be permitted in certain circumstances with sufficient motivation.	High Significance
IIIB	Such a resource might have similar significances to those of a Grade III A resource, but to a lesser degree.	Resource must be retained where possible where not possible it must be fully investigated and/or mitigated.	Medium Significance
IIIC	Such a resource is of contributing significance.	Resource must be satisfactorily studied before impact. If the recording already done (such as in an HIA or permit application) is not sufficient, further recording or even mitigation may be required.	Low Significance
NCW	A resource that, after appropriate investigation, has been determined to not have enough heritage significance to be retained as part of the National Estate.	No further actions under the NHRA are required. This must be motivated by the applicant or the consultant and approved by the authority.	No research potential or other cultural significance

Table 3 - Rating system for built environment resources

Grading	Description of Resource	Examples of Possible Management Strategies	Heritage Significance
I	Heritage resources with qualities so exceptional that they are of special national significance. Current examples: Robben Island	May be declared as a National Heritage Site managed by SAHRA.	Highest Significance
II	Heritage resources with special qualities which make them significant in the context of a province or region, but do not fulfil the criteria for Grade I status. Current examples: St George's Cathedral, Community House	May be declared as a Provincial Heritage Site managed by Provincial Heritage Authority.	Exceptionally High Significance
II	Such a resource contributes to the environmental quality or cultural significance of a larger area and fulfils one of the criteria set out in section 3(3) of the Act but that does not fulfil the criteria for Grade II status. Grade III sites may be formally protected by placement on the Heritage Register.		

Grading	Description of Resource	Examples of Possible Management Strategies	Heritage Significance
IIIA	Such a resource must be an excellent example of its kind or must be sufficiently rare. These are heritage resources which are significant in the context of an area.	This grading is applied to buildings and sites that have sufficient intrinsic significance to be regarded as local heritage resources; and are significant enough to warrant that any alteration, both internal and external, is regulated. Such buildings and sites may be representative, being excellent examples of their kind, or may be rare. In either case, they should receive maximum protection at local level.	High Significance
IIIB	Such a resource might have similar significances to those of a Grade III A resource, but to a lesser degree. These are heritage resources which are significant in the context of a townscape, neighbourhood, settlement, or community.	Like Grade IIIA buildings and sites, such buildings and sites may be representative, being excellent examples of their kind, or may be rare, but less so than Grade IIIA examples. They would receive less stringent protection than Grade IIIA buildings and sites at local level.	Medium Significance
IIIC	Such a resource is of contributing significance to the environs These are heritage resources which are significant in the context of a streetscape or direct neighbourhood.	This grading is applied to buildings and/or sites whose significance is contextual, i.e. in large part due to its contribution to the character or significance of the environs. These buildings and sites should, consequently, only be regulated if the significance of the environs is sufficient to warrant protective measures, regardless of whether the site falls within a Conservation or Heritage Area. Internal alterations should not necessarily be regulated.	Low Significance
NCW	A resource that, after appropriate investigation, has been determined to not have enough heritage significance to be retained as part of the National Estate.	No further actions under the NHFA are required. This must be motivated by the applicant and approved by the authority. Section 34 can even be lifted by HWC for structures in this category if they are older than 60 years.	No research potential or other cultural significance

3.2.1 Methodology used in Determining the Significance of Environmental Impacts

The methodology used to determine the environmental impact significance was provided by EIMS and is explained in **Appendix B**.

4 DESKTOP STUDY

4.1 OVERVIEW OF THE STUDY AREA AND SURROUNDING LANDSCAPE

For the last 200 000 years, the West Coast has been an attractive region for hunter-gatherers, pastoralist groups and modern-day fisher people, due to its wealth of marine and terrestrial resources. The ocean is an integral part of West Coast's natural and cultural heritage. West Coast residents are proud of their unique 'Weskus' culture. According to Schultz (2010), 'a family's association with the West Coast is their claim to Khoisan heritage as constituting a historical bond with the cape West Coast".

4.1.1 PRE-COLONIAL ARCHAEOLOGICAL CONTEXT

Marine resources have a long history of human exploitation. Evidence from archaeological sites suggest that the West Coast region was occupied from the Early Stone Age (ESA) through to the Middle Stone Age (MSA) and Later Stone Age (LSA), up until the arrival of early European settlers from the 18th century onwards. There are numerous sites (including shell middens, stratified cave deposits, rock art, stone tools, and fish traps) recorded along the coast that demonstrate that the rocky shorelines were attractive to hunter-gatherers through time (e.g., Halkett, 2003; Halkett and Dewar, 2007; Sadr *et al.*, 1992; Kaplan, 1993, 1996, 1998, 2008, 2011a, 2014; Morris, 2006; Webley, 2009; Jerardino *et al.*, 2013). Much of what we know about settlement, subsistence strategies and diet along the coast is linked to these shorelines (Parkington 1976; Hart & Miller, 1994). Whilst gorges and stone sinkers are probably the best evidence for technical fishing equipment in the LSA, marine shell middens also demonstrate that the coastal zone was particularly favoured by LSA people (Deacon, 1995).

4.1.2 SHELL MIDDENS

Marine shell middens have been identified within 1km of the coastline, near estuaries and in dune fields which lie adjacent to rock shores. While pre-historic people likely favoured the rocky shorelines for ease of access to marine resources, middens have also been found further inland, where people would have been able to exploit additional resources such as game life and fresh water.

In some instances, these shell middens are associated with domestic artefactual debris which suggests that they in fact represent occupation sites of long duration. Whilst the opposite can be said for midden sites that do not contain a formal stone artefact component, and instead may represent visits of short duration. These pre-historic people were the ancestors of the San and Khoikhoi.

According to archaeologists, several shell middens in the Vredenburg Peninsula are associated with both San and Khoikhoi groups who were harvesting the shorelines and estuaries of the West Coast in a sustainable and patterned manner (Parkington et al. 1988).

4.1.3 STONE FISH TRAPS

The remains of fish traps (*visvywers; stone-walled tidal fish traps*) have been recorded along the South African coastline from St Helena Bay to Mossel Bay (Goodwin, 1946; Avery 1975; Phillip et al , 2010). Along the south-western coastline, these traps, which use "the tidal range to allow fish to enter pre-built enclosures and be trapped at low tide", provide evidence of early fishing techniques. The preserved fish traps vary in shape, size, and spatial complexity. Identifying the architects of these traps is, however a contentious issue.

Initially, researchers believed that the fish traps on the south coast were ancient maritime resource systems that originated among LSA people after 2000 years ago with the arrival of Khoikhoi herders (Avery, 1975; Gribble, 2006). More recent research suggests that the development of fish traps along the southern and western coasts dates to the 19th century. Furthermore, these structures may have been introduced by European farmers as part of the farming-fishing system when intensive exploitation of inshore fish by local farmers occurred (Hine, 2006, 2009; Hine et al. 2010).

In 1987, Graham Avery recorded a tidal fish trap in Mauritzbaai, south of Jacobsbaai (Kaplan 2004). Hart and Halkett (1992) have also identified the remains of at least six traps in the intertidal zone at Wilde Varkens Valley, St Helena Bay.

4.1.4 INDIGENOUS PEOPLES

4.1.5 INTRODUCTION

Before the colonial era, there were several diverse ancient tribes who traversed the valleys and plains of the present-day West Coast region of South Africa. The origins of the West Coast fishing communities can be traced back to the San and Khoikhoi peoples who lived within this region. Together, the Khoi and the San are the First Peoples of South Africa.

In 1928, a German physical anthropologist Leonard Schultze, created the term 'Khoisan', to stress the similarities between the Khoikhoi and the San (Le Fleur and Jansen, 2013; Secorun, 2018). The settlers used the term 'Bushmen' when referring to the San, and many of whom the colonists' called 'Bushmen' were, in fact, Khoikhoi or former Hottentot. Today, this term is considered derogatory, and instead, scholars would rather refer to hunters and herders together as 'Khoisan'.[1]

[1] https://www.sahistory.org.za/article/khoisan

It should be noted that although Khoi and San Peoples may share some experiences, culturally, they remain two distinct groups, and the general preference amongst both Khoi and San people is to be called by their clan names.

4.1.6 THE SAN[2]

During almost the entire Holocene period, small groups of San hunter-gatherers were present in southern Africa. The San are the direct descendants of the first peoples of southern Africa.[3] It should be noted that the term "San" is used to cover over a dozen distinct hunter-gatherer groups who speak distinctive "click" languages (incl. the Khwe, !Xun, Juhoansi, Naro, Ju|'hoansi and other groups). These groups lived across Namibia, South Africa, Botswana, and Zimbabwe. The San were small groups of nomadic people who lived by the ethos of "all people are equal". They hunted and gathered resources and did not keep livestock.

It is generally agreed amongst academics that the San were the first inhabitants of the Cape region. During the latter part of the Holocene, there were hunter-gatherers living on the West Coast who made seasonal use of the coastal resources (Parkington and Hall, 1987). Several archaeological sites, including Duyker Eiland, which is in Britannia Bay, confirmed the importance of shellfish, seals, marine birds, crayfish, and beached whales as a food source for the local inhabitants during this time (Robertshaw, 1979).

4.1.7 THE INTRODUCTION OF KHOIKHOI

For thousands of years, the Khoikhoi[4] people have occupied and moved around Southern Africa as nomadic herders. The Khoikhoi were large groups of nomadic herders who owned substantial herds (incl. cattle and sheep) and migrated for pasture, water, and food resources. It is understood that Khoikhoi peoples have a spiritual connection to land, where land is perceived as a gift from nature to be cared for

Note that the Khoikhoi term is an umbrella term which refers to different tribes. The Khoikhoi people comprise four historical groupings: the Griqua, Nama, Koranna and Cape Khoi (incl further subgroupings). Today, the Nama people are primarily located in the Northern Cape. The Griqua are in the Western Cape, Eastern Cape, KwaZulu Natal and Gauteng, and various other parts of the country. The Korana people, live primarily in Kimberly and the Free State. The Cape Khoi are in the Western and Eastern Cape.

Evidence suggests that around 2000 years ago, the pastoralist Khoikhoi entered South Africa along the West Coast into the Cape region (Smith, 1987, Sealy and Yates 1994; Henshilwood, 1996;

---

[2] *The Khoikhoi and the early Dutch settlers called these groups Soaqua (literally 'San').*
[3] *https://www.hr-dp.org/files/2015/07/06/30516746.pdf*
[4] *Note that the use of the terminology of Khoikhoi or Khoekhoe is used by various scholars and writers. This report will be using Khoikhoi as the standard*

Avery, 1975; Schweitzer, 1979; Deacon et al., 1978;). They brought a new way of life, from its northern origins, to South Africa. The Khoikhoi introduced domesticated livestock and new material culture (incl. pottery) into the region. They relied more on sheep as a meat resource and hunted and gathered (Schapera, 1933). Groups living close to the coast would also exploit shellfish, seals, and other marine resources. The St Helena Bay (Slipper Bay) region appears to have provided the Khoikhoi with invaluable resources, including whale meat obtained via 'cetacean traps[5].

One of the most important West Coast pastoralist sites, Kasteelberg, is an open-air archaeological site located 4km from the coast. It provides evidence of occupation by herders between 1800 and 1600 years ago (Klein, 1986). The occupants of the site focused on harvesting seals and the presence of sheep bones also indicated that the inhabitants were most likely herding domestic stock (Klein, 1986; Smith, 2006).

It is thought that the indigenous people in the Cape populated a region from Northern Namibia to the Cape of Good Hope and from the Atlantic Ocean to the Fish River in the East (Figure 4). The area between Saldanha and Vredenburg was occupied by the CochoQua and the CheriGuriQua (GuriQua) group occupied the lower Berg River area which included St Helena Bay and regions around Pickelberg.

Some researchers choose to use the term Peninsular Khoikhoi" when referring to the *Gorachoquas, Goringhaiquas* and the *Goringhaiconas* ("strandlopers") and "Surrounding Khoikhoi" for the *Cochoqua, Chainouqua* and *Hessequa* (see Brink, 2000; Nienaber, 1989; Wilson, 1990).

[5] "Places where whales often strand themselves along the shore are known as 'cetacean traps'. These are areas where anomalies in the earth's magnetic field cross the shoreline, and where there are offshore reefs." (http://www.saveabeach.com/history.html)

Figure 4 – Map illustrating the approximate locations of Khoikhoi before contact with the Europeans (in the southwest Cape ca. 1650) (Source: Elphick and Giliomee, 1979).

In the pre-colonial era, the relations between the Khoikhoi and the San were relatively stable due to a mutual acknowledgement of territories. Although the San and Khoikhoi seemed to have co-existed for a period, it appears that, to some degree, the San groups were displaced (Elphick, 1977; Parkington *et al.* 1986). It's assumed that the Khoikhoi moved into areas that had previously been utilised by the San, thus forcing the San to move into more isolated coastal regions (Manhire, 1987). The San's "settlement and subsistence strategy changed from one based on the large-band occupation of open areas and the hunting of large game towards the more intensive utilisation of rock shelters, in small groups and a foraging-based economy" (Barnard, 1992). Unfortunately, indigenous groups who lived on the coast were the first people to be severely impacted by colonial oppression (Boezak, 2017).

4.1.8 COLONIAL DISPOSSESSION

First contact between indigenous pastoralist groups and Europeans occurred during the 15th and 16th centuries when Portuguese mariners would sail down the coast. Before the Dutch East India Company's ("VOC") governance over the southernmost tip of Africa, European merchants, and travellers en route to or from Asia would call in at the natural harbour of Saldanha Bay for refreshment. Encampments were also set up along the coast by survivors of shipwrecks, and in their journals, they would recall how they met and traded with indigenous groups (Smith, 1985; Raven-Hart, 1967). Written records reveal that in 1497, the GuriQua and the San (SonQua) witnessed the arrival and departure of Vasco da Gama in St Helena Bay (Raven-Hart, 1967; Axelson,1996). Although the Saldanha Bay harbour was more sheltered than Table Bay and

allowed for the crews to trade livestock from the Khoikhoi in the area (Raven-Hart, 1967; Smith, 1965), there was not enough fresh water available to allow for the establishment of large permanent settlements.

It was only in 1652 that the VOC decided to occupy the Cape and establish the first permanent European settlement in South Africa. The VOC established a station at Table Bay to supply Company fleets travelling between Europe and the Indies with refreshments (i.e., meat, wheat, vegetables, and freshwater) (Ward, 2009). When the Dutch colonists arrived, they encountered several Khoikhoi groups. The largest concentration of Khoikhoi lived in the lush pasture lands of the south-western Cape region.

Initially, the relationship between the Dutch and the Khoikhoi was one of cooperation, and the VOC established trading agreements with local chiefs to get regular supplies of fresh meat (Elphick, 1977). As the colony grew, the VOC decided to decrease their dependency on local trade with the Khoikhoi. Their alternative plan was to give land to free burghers to supply meat and grain to the Company.

Khoikhoi and San lives were impacted upon by both internal strife and direct conflict with the Europeans over the disregard of traditional customs, the privatisation of land, and exhausting indigenous resources (i.e., overfishing and farming). As the Dutch took over more of the Khoikhoi's grazing land for farms, much of the Khoikhoi and San peoples' traditional lands were dispossessed (Elphick, 1977; Bredekamp, 1986; Elphick and Malherbe 1989; SAHistory, 2012). In 1657, the Goringhaiqua tribe were ordered to move to the east of the Liesbeeck boundary and this 'eviction' event would be instrumental for the first war against colonial intrusion (Bredekamp and Newton-King, 1984). The First Khoikhoi-Dutch War lasted the whole of 1659 (Elphick, 1977).

According to Sleigh (1993: 148), "In 1672, two sons of the weakened Peninsular Khoisan chiefs signed a contract, which they probably did not fully understand, and sold huge tracts of land from Table Bay to Saldanha Bay in the North and to the Hottentots Hollands mountains in the East to the VOC for an incredible low price (which they did not even fully receive)".

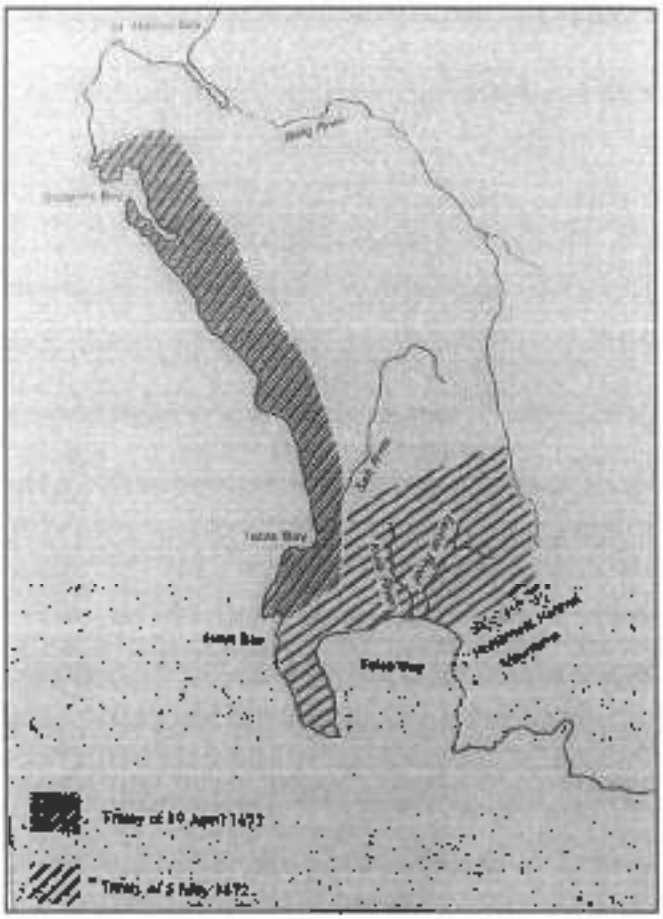

Figure 5 – Map illustrating the 1672 land 'sale' (Source: Boonzaier et al., 1996: 79).

After a few more instances of territories being ignored and further land appropriation, another war of resistance was initiated by the Cochoqua, and the Second Khoikhoi-Dutch War commenced (1673-1677). This led to more Khoikhoi groups being forced to relocate to areas further up the coast.

According to writings of early settlers, it appears that some San groups, who pursued a hunting and foraging lifestyle, may have still resided in the mountainous regions of the Cape where they were less likely to clash with the Khoi or Dutch settlers (Parkington et al. 1988). Regions that were less desirable for the colonists, such as Namequaland, became places of refuge for the San and Khoikhoi who were able to continue many aspects of their traditional ways of life in this area for some time (Raper and Boucher, 1988).

In 1713, the small-pox epidemic led to the death of many Khoikhoi people living in the south-western Cape. The surviving Khoisan became assimilated as domestic/farm workers due to the high demand for labour by the Dutch. In rural areas, the Khoisan were forced into what was referred to as semi-bonded labour (Ward, 2009).

By the late 18th century, the Cape settler colony's territories incorporated the Berg (c. 1790), Olifants (1750), and Buffels (1798) rivers.

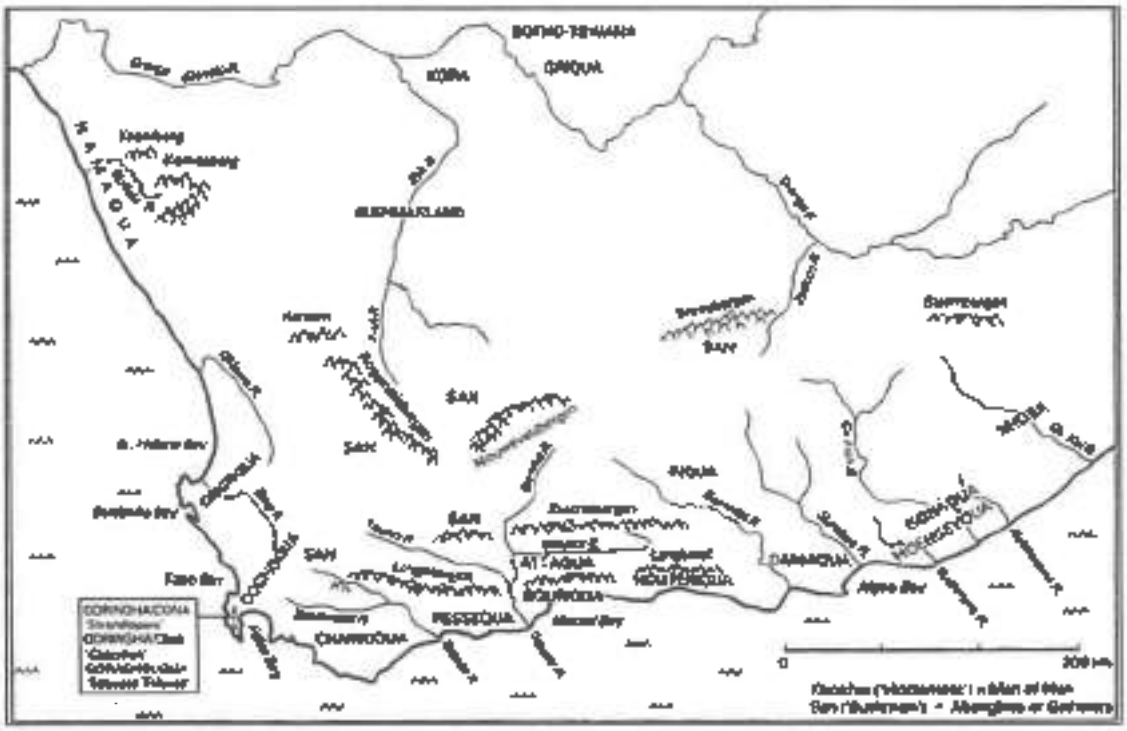

Figure 6 – Map illustrating the Khoikhoi and San groupings in South Africa during the 17th and 18th centuries (Source: Boeseken and van den Berg, 1955).

4.1.9 THE HISTORY OF FISHING ON THE WEST COAST

4.1.10 17TH CENTURY

During the 17th century, the VOC established an outpost at St Helena Bay (Saldanha Bay Municipality, 2020). From 1670, free burgers started to fish regularly in St Helena Bay (Sleigh, 1993). They introduced methods to the region that were not previously available to indigenous fishermen, such as metal hooks, boats, nets and bulk processing and storage.

4.1.11 18TH CENTURY

During the 18th century, the Cape settler's economy was primarily based on slave labour which was imported from Asia and East Africa. The agricultural sector which was maintained by free burghers (freed from Company service) was not stable and due to the trade of the Khoikhoi's livestock being intermittent, the settlers had to make alternative arrangements for food resources. This led to Robben Island being exploited for seals, penguins, and seabirds (Penn, 1996; Ward, 2009). Large rural landowners established private coastal fishing posts to supply marine resources to the Company, the local region, passing ships and for export (Muller 1942; De Kock 1966). Soon, Dassen Island, Saldanha Bay and St Helena Bay developed as significant centres to supply the

VOC with additional resources to sustain the growing number of people in the Cape colony, including the substantial number of slaves kept by the Company. According to Sleigh (1993), the slaves were given salted fish, seal meat, penguin, and bird eggs whilst the rest of the colony preferred to consume meat.

According to Marincowitz (1985: 40–46) *"With exclusive land grants closing the north-western frontier, from the 1740s growing numbers of ex-slaves, dispossessed Khoekhoe, failed farmers, evicted tenants and bywoners (tenant farmers), new immigrants and fugitives from colonial and military justice moved onto the beaches of the west coast".*

Early fishing, sealing and whaling activities, by European and American whalers, around Saldanha Bay, especially near Marcus Island/Outer Bay and at Salamander Point, have been extensively documented in the archival/historical record (*Griffiths et al. 2004;* David & van Sittert, 2008). Although the inshore whale population declined after 1830, processing continued at Donkergat in Saldanha Bay (Halkett 1998).

4.1.12 19TH CENTURY

By the mid 19th century, scattered subsistence communities had emerged along the West Coast. Before the arrival of industrial fisheries, residents in St Helena Bay employed basic fishing technology (small-scale line fishing, beach seine nets and rowing boats) and fishing activities were informally organized by boat and net owners.

Malay slaves and other residents moved into the region to work as farm labourers. Over time, the unique fishing skills of enslaved Malay people interminglied with the fishing skills of the indigenous people. This led to the establishment of small fishing villages along the West Coast (incl. Saldanha, Langebaan and St Helena Bay).

After the emancipation of slaves, new laws were introduced to control both the freedom of movement and independent livelihoods of people who did not own land. This forced fishermen on the West Coast "to either develop artisanal skills, become wage labourers or squat on coastal government land to eke out a living from small scale production and seasonal work" (Van Sittert 1992: 12-14).

Using business capital in both the local and international markets, entrepreneurs were able to lease Crown land and establish coastal industries along the West Coast (Van Sittert 1992).

By the 1880s, a Cape Town-based trading company, Stephan Brothers, was able to monopolise the West Coast trade. The company bought the main grain shipping points along the West Coast,

including the southern shore of St Helena Bay, where they established Laaiplek (translates to 'loading place') at the mouth of the Berg River (Van Sittert 2001: 197).

4.1.13 20TH CENTURY

Although the local fishing industry on the West Coast employed a substantial number of locals at the start of the 20th century, the industry is associated with a history of hardship. The industry's collapse in the mid-20th century left numerous West Coast communities impoverished (Van Sittert, 2001). Despite all the obstacles thrown at them, the West Coast fishing communities were resilient and continued their fishing tradition throughout the 20th century.

Historically, small-scale fishers have constantly had to compete against big scale fisheries. For example, Piketberg coastal fisheries used a method of fishing called beach seining to supply inland farmers with cheap ration fish. When there was a decline in snoek sources further south, Italian immigrant fishermen from Cape Town travelled up the West Coast on boats with set nets. Ultimately, their method of fishing impacted the supply of fish for the sedentary fishermen.

By 1900, the Stephan Brothers company were in control of nearly every suitable bay from Saldanha Bay to Lamberts Bay. They also owned numerous farms which were often acquired in exchange for debt. In 1909, the company negotiated an agreement with the State to establish an Exclusive Trek Seine Fishing Zone along the Malmesbury coast (Van Sittert 1992: xxxii). This move meant that the company was able to dominate a new manufacturing industry which further exacerbated resource owners and local fishermen.

During World War One, there was a crayfish canning boom in the Cape. The sourcing of crayfish moved rapidly up the West Coast during this period (Griffiths et al. 2004). By the early 1920s, the overexploitation of crayfish resulted in an exhaustion of crayfish stocks and West Coast factories were forced to close. This meant that the small-scale seine fishermen, and fishermen who netted in the backwaters, were left even more vulnerable to the financial depression of the 1930s.

Then, in 1934, in an act of retaliation, "Saldanha Bay fishermen invaded the Piketberg area on motorboats carrying Italian lampara nets and, with the support of Government, wiped out the non-motorised Berg River inshore fisheries run by consortiums of farmers, fishery owners and canners" (Van Sittert 1992: 211–237).

In 1951, increasing catches along the West Coast, meant that both skippers and fishermen yielded good financial returns. By 1955, South Africa had the largest fishing industry in the southern hemisphere (Griffiths et al. 2004).

With the Apartheid system arriving, the indigenous identity of the Khoisan was further disrupted through the Race Classification Act and the Populations Registration Act. The Khoisan were forcibly categorised as "Coloured" (Boswell and Thornton, 2021). This label further dispossessed the

people from their heritage. Under the Group Areas Act (1950) the towns of the West Coast were divided into segregated residential and business areas. The forced removals marked yet another era of forced removals from areas that indigenous people occupied. Despite the discrimination, the communities continued their tradition of fishing that had been passed on through the generations of fisher families.

4.1.14 MARITIME HERITAGE RESOURCES

The following section was developed by maritime archaeologist Vanessa Maitland.

The first recorded European voyages down the west coast of Africa were by the Portuguese. When the first Portuguese explorers travelled down the west African coast, they stuck close to the coastline, to map the land. However, occasionally they were swept towards the Americas, as is evident by the fate of the fleet of Pedro Alvares Cabral, in 1500. This was first Portuguese fleet which was to sail annually to the Indies. Twenty days after the fleet left Brazil, which they had "discovered", it was struck by storms and four ships, including the one under command of Bartolomeu Dias, foundered somewhere in the southern Atlantic. Different researchers put them anywhere between Tristan da Cunha and the Cape.

Bartolomeu Dias and his fleet passed the Orange River Mouth in 1487/1488 (Axelson, 1973). Thereafter, the rate of exploration and trade increased exponentially, as is evidenced by the increase in shipwrecks over the centuries. These early voyages were not well documented, and the archives often merely report that a fleet of a certain number of vessels left and only a certain amount returned, with only vague references to their place and manner of loss. Therefore, there are many undocumented wrecks, along the coastline and even more offshore.

There is some anecdotal evidence that the Phoenicians circumnavigated Africa (Herodotus, 1954). If this is true, these ships had to stick right to the coastline and therefore are likely to be inshore. There's increasing evidence that the Chinese voyages of the 1400s explored parts, if not all, of the African coast (Paine, 2013). However, once again the archival evidence to date, and availability to Western researchers, limits this knowledge.

There are many ships that are only recorded as having disappeared between Europe and the Far East and Americas. As well as between local ports. The mechanics of sailing vessels and winds meant that for a ship to get from Europe to the Cape, they often sailed via South America. There are also numerous missing U-boats and other war vessels from WW1 and WW2 that may be found.

Thousands of ships have disappeared in the southern Atlantic Ocean, a portion of these can be seen in **Figure 7**. There are numerous historical reports of abandoned vessels being seen by other ships (**Figure 8**).

Figure 7 - A portion of the ships wrecked off South Africa and in the southern Atlantic

on the Wednesday returned for my North.

Captain Worsnop, of the ship Waimate, which arrived at Port Chalmers from London yesterday, reported that on May 22nd, in latitude 17·39 S., longitude 33·45 W., he encountered the hull of the British ship Kakanui which caught fire when bound from London to Melbourne and was abandoned by the crew on April 28. The vessel was completely burnt out, nothing but the shell being left, with a mass of metal and burning in the bottom of the hold. As the hull was lying right in the track of vessels, and was a dangerous obstruction, Captain Worsnop had a steps knocked out of the bottom, and it was expected that it would sink in a couple of days.

Figure 8 - Report in The Auckland Star 26-07-1895, by the Waimate on the drifting hulk of the Salsette

4.1.15 ARCHIVAL AND HISTORICAL MAPS

Relevant historical maps were studied to identify the tribes that historically occupied the West Coast region. Historical maps for various years (1747 and 1850) were available for utilisation in the background study.

4.1.15.1 MAP OF CAPE OF GOOD HOPE, 1747

(Publisher: Pierre d'Hondt)

The map depicted in **Figure 9** is titled Kaart van de Kaap de Goede Hoop ("Map of Cape of Good Hope"). The map dates from 1747. The land surveyor/mapmaker was Jacques Nicolas Bellin (Publisher: Pierre d'Hondt).

4.1.15.2 SECTION OF CAPE COLONY, 1812

(David Rumsey Historical Map Collection: Image No. 0028063).

The map depicted in **Figure 10** is titled "Cape Colony". The full title of the map is "Colony of the Cape of Good Hope. ". The map dates from 1812. The map was drawn from Mr. Barrow's survey by A Arrowsmith and S. Lewis (Publisher: Thomas & Andrews). "Relief shown by hachures".

4.1.15.3 SECTION OF SOUTH AFRICA (CAPE COLONY), 1832

(David Rumsey Historical Map Collection: Image No. 0247106).

The map depicted in **Figure 11** is titled "South Africa (Cape Colony)". The map dates from 1832. The authors of the map were W.M. Higgins and D. John (Publisher: W.S. Orr & Co.).

4.1.15.4 CAPE COLONY, 1850

(Publisher: J. & F. Tallis)

The map depicted in **Figure 13** is titled "Cape Colony". The map dates from 1850. The map was drawn and engraved by John Rapkin, and illustrations were by H. Warren (Publisher: J. & F. Tallis).

4.1.15.5 SECTION OF CAPE PROVINCE, TRANSVAAL, &C. – WESTERN SECTION, 1922

(David Rumsey Historical Map Collection: Image No. 2113082)

The map depicted in **Figure 12** is titled "Cape Province, Transvaal, &c. – western section". The map dates from 1922. The author of the map was John Bartholomew and Son (Publisher: The Times).

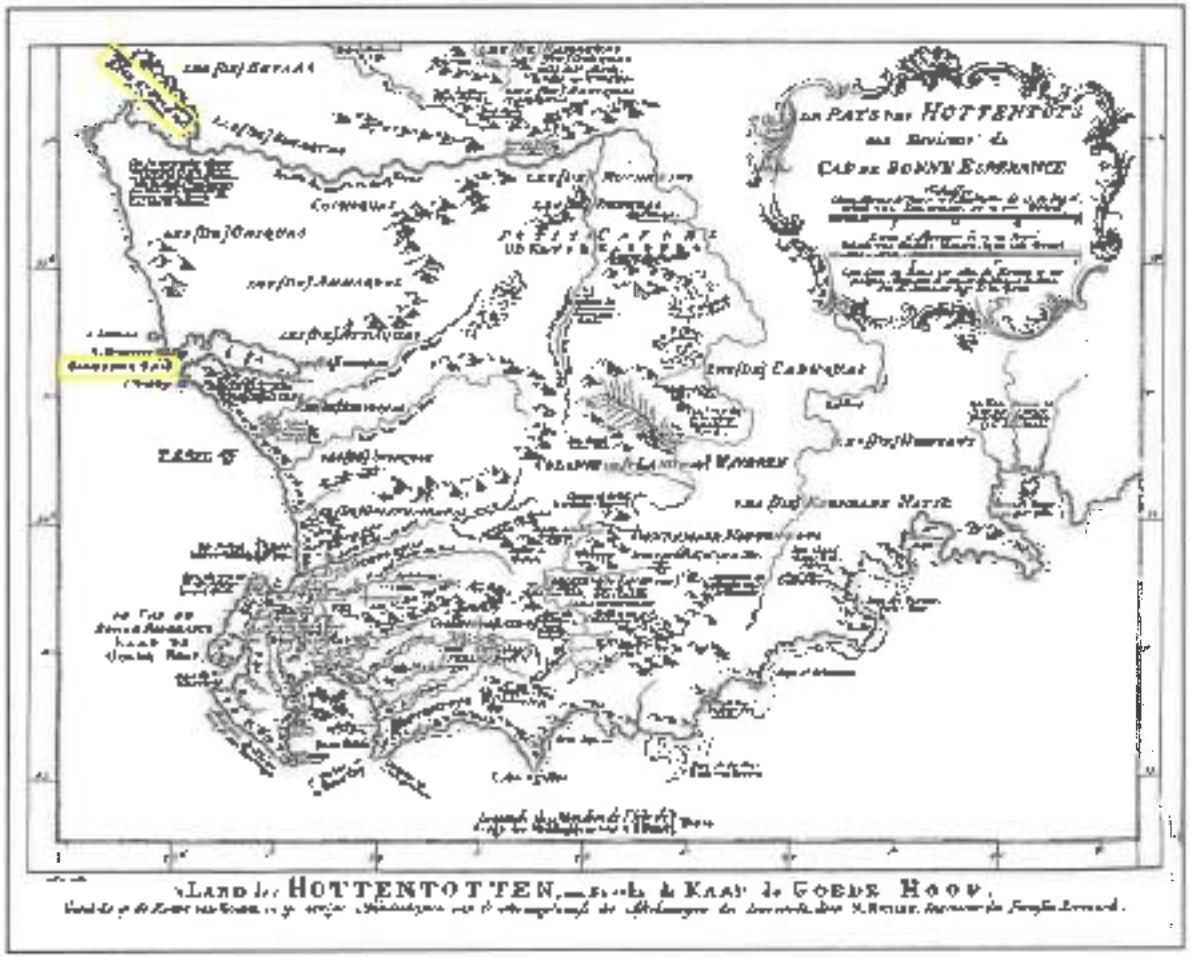

Figure 6 – 1747 historical map titled "Map of Cape of Good Hope"[6] (yellow polygons: West Coast towns).

4.2 PREVIOUS HERITAGE IMPACT ASSESSMENT REPORTS FROM THE STUDY AREA AND SURROUNDINGS

A search of the South African Heritage Resources Information System (SAHRIS) database revealed that numerous archaeological and heritage impact assessments had been undertaken within the surroundings of the West Coast. These reports solely focused on tangible heritage and do not fully address the intangible heritage of the West Coast region. Therefore, this report will not reference these impact assessments.

5 INTANGIBLE HERITAGE

'Intangible heritage' (also referred to as "Living Heritage") is a term which is used to describe "aesthetic, spiritual, symbolic or other social values people may associate with a site, as well as rituals, music, language, know-how, oral traditions and the cultural spaces in which these 'living heritage' traditions are played out."[8] Through its efforts to safeguard intangible heritage UNESCO and its member states developed the Convention for the Safeguarding of the Intangible Cultural Heritage (ICHC).[9]

The following section is extracted from a UNESCO webpage that explains the importance of Intangible Heritage:

"While fragile, intangible cultural heritage is an important factor in maintaining cultural diversity in the face of growing globalization. An understanding of the intangible cultural heritage of different communities helps with intercultural dialogue and encourages mutual respect for other ways of life.

The importance of intangible cultural heritage is not the cultural manifestation itself but rather the wealth of knowledge and skills that is transmitted through it from one generation to the next. The social and economic value of this transmission of knowledge is relevant for minority groups and for mainstream social groups within a State, and is as important for developing States as for developed ones.

Intangible heritage is:

- *Traditional, contemporary, and living at the same time: intangible cultural heritage does not only represent inherited traditions from the past but also contemporary rural and urban practices in which diverse cultural groups take part.*
- *Inclusive: we may share expressions of intangible cultural heritage that are similar to those practised by others. Whether they are from the neighbouring village, from a city on the opposite side of the world, or have been adopted by peoples who have migrated and settled in a different region, they all are intangible cultural heritage: they have been passed from one generation to another, have evolved in response to their environments and they constitute to giving us a sense of identity and continuity, providing a link from our past, through the present, and into our future. Intangible cultural heritage does not give rise to questions of whether or not certain practices are specific to a culture. It constitutes to social cohesion, encouraging a sense of identity and responsibility which helps individuals to feel part of one or different communities and to feel part of society at large.*
- *Representative: intangible cultural heritage is not merely valued as a cultural good, on a comparative basis, for its exclusivity or its exceptional value. It thrives on its basis in*

[8] Report from meeting to define Intangible Cultural Heritage, Piedmont (Italy) March 2001 (https://ich.unesco.org/doc/src/00077-EN.pdf. accessed 22 July 2022).
[9] UNESCO. 2003. Convention for the Safeguarding of the Intangible Cultural Heritage

communities and depends on those whose knowledge of traditions, skills and customs are passed on to the rest of the community, from generation to generation, or to other communities.

- ***Community-based: Intangible cultural heritage can only be heritage when it is recognized as such by the communities, groups or individuals that create, maintain, and transmit it – without their recognition, nobody else can decide for them that a given expression or practice is their heritage."***

In this assessment, marine-related intangible cultural heritage and people's connection to the ocean is relevant. This type of heritage incorporates the unique ethos and identity of specific places linked with fishing villages; oral history; popular memory; cultural traditions; indigenous knowledge systems, rituals, beliefs, and practices (e.g., fishing techniques) associated with the ocean.

In some cultures, the ocean is regarded as a spiritual realm filled with healing powers and a means to connect to one's ancestors. Gabie (2014) explains how water is the Khoisan's "...'source of life, a sense of belonging and their permanence to nature". Water is vital for various rituals and cleansing ceremonies.

According to Boswell and Thornton (2021), the Khoisan "advocate for deep connections and complementarity between humans and nature, recognising the agency and 'direction' provided by nature to humanity"

Considering that the ICHC emphasises the declaration and listing of forms of Intangible Heritage, it can lead to a diminished recognition of intangible heritage not listed or formally recognised (Gimblett, 2004). The ICHC requires a State Party to develop an inventory of intangible heritage within their country or territory and then take measures to safeguard community participation (Article 11(a)) (Deacon and Smeets, 20013). As Smith (2015) argues, the European Authorised Heritage Discourse within UNESCO emphasises the declaration and the importance of heritage and things as defined by experts or those entities and nation states promoting their discourse. The ICHC, however, did provide the opportunity for communities on a sub-national level to promote and give legitimacy to their intangible heritage. Unfortunately, the ICHC and its operational standards place the responsibility of assessment, nomination, and listing on the State Parties. This leads to a gatekeeper process in which these Parties can decide and control what is listed and nominated through their national discourse to the detriment of the community or grouping.

The Khoisan has historical experienced marginalisation and stigmatisation since the onset of colonialisation in Southern Africa. Section 4 of this report provides a narrative of the general history of the Khoisan on the West Coast and Western Cape, indicating a gradual disbanding of communities and cultural fabric of these indigenous groupings due to colonialism and economic

influences. The last decade has however shown a renewed interest and growth in claiming their roots and history through the resurgence movement.

Natural Justice (2016) submitted that strides were made in the recognition and legitimising of the Khoisan. However, entrenched continuing historic race classifications and the lack of leadership recognition through such issues as the dragging finalisation of the Traditional and Khoi-San Leadership Bill, before its promulgation in 2019, is robbing these communities of a voice and standing within the larger South African landscape. This speaks to the recognition of their culture that is inclusive of tangible and intangible heritage.

6 STAKEHOLDER ENGAGEMENT

6.1 INTRODUCTION

Public meetings were conducted by EIMS from 29 August to 3 September 2022 (Table 4) to inform Interested and Affected Parties (IAPs) of the proposed project and associated application process and allow them to raise comments/concerns.

Table 4 – Information relating to the public participation meetings

Town	Venue	Date	Time
Hout Bay	Hout Bay Public Library	Monday 29 August 2022	16:00 – 18:00
Cape Town	Life Conference Centre (Three Anchor Bay)	Tuesday 30 August 2022	16:00 – 18:00
Saldanha	Hoedjies Bay Hotel	Wednesday 31 August 2022	16:00 – 18:00
Lamberts Bay	Community Hall	Thursday 1 September 2022	16:00 – 18:00
Vredenburg	Eric Baker Hall	Friday 2 September 2022	16:00 – 18:00
Port Nolloth	Port Nolloth Country Club	Saturday 3 September 2022	10:00 – 12:00

6.1.1 Issues Raised

The Public Participation process did raise some comments on heritage-related issues. Several individuals who attended the public meetings raised concerns about how their heritage will be impacted by the proposed project.

The people regard the ocean as an inseperable part of their identity. "The sea is in our blood" is a common expression community members use. The ocean and its marine resources symbolise an important part of their history and heritage. They have relied on the ocean for survival as their skill sets are catered toward fishing.

6.1.2 Hout Bay

During the public meeting at the Hout Bay Public Library no pertinent mention was made to heritage issues.

6.1.3 Saldanha

6.1.3.1 A MS MOSTERT RAISED THE FOLLOWING CONCERNS:

- Explained their close association with the ocean as small scale fishers and that an impact by the project will impact on their way of life and social cohesion.

JC28

6.1.3.2 A WEST COAST CHIEF KHAESEN MAART RAISED SEVERAL POINTS:

- Mr Maart explained that the ocean is a precious and spiritual way of life. They have always lived in harmony with the ocean, and through generations, they have conserved and managed their own interaction with the ocean and its bounty.

6.1.4 Lambertsbay

6.1.4.1 MR NIKOLAAS BOOYSEN

- Objected that the San communities are still being ignored and not considered to interact with first to obtain free and informed consent.

6.1.5 Focus Discussions

During and after the consultation process for the Searcher Seismic application held in July 2022, focused meetings were held with selected representatives and grouping identified during the public engagements. These meetings were conducted by members of PGS. During the meeting, it was indicated that the TGS application will be forthcoming and that PGS will be the heritage consultant for this application as well.

Table 5 - Summary of discussion with groups

Area	Date	Interlocutors	Association	Themes and issues identified and discussed
Lambertsbaai	18/08/2022	Rosey Shoshola Giovanni Cloete	Small scale fishers	• Activities in small-scale fisheries keep youth away from social issues such as substance abuse. • The waning of small-scale fisheries and their economic decline are linked to social issues such as gangsterism, substance abuse, and teenage pregnancies. • Their heritage is closely linked to their life as a fishing community. Their interaction between families and various groupings within the community. • Activities such as bartering, food dishes linked to specific days, and local and community festivals are intrinsically linked to their life as fishers. • If they would not be able to continue their fishing activities will lead to a further decline in their community cohesion and cultural character. • There is a definite link between declining fish yield and industrial impacts • They feel there is already evidence of previous seismic activity's impact at the end of 2021 on snoek catches in this year, 2022.
Lambertsbaai	18/08/2022	Anthony Andrews Nicolaas Booysen	West Coast Gurigua Council	• Focus and emphasis was placed on the need for Free, Prior and Informed Consent (FPIC) required from the Girqua Council and group as stipulated United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP). • They are not heard and engage with. • The interlocutors further stressed their position as representatives and part of the Gurigua as first people of the West Coast • They explained that their way of live is linked with the ocean as well as the land as some of the Guriqua had to move towards ocean subsistence after displacement from farms • They are indelibly linked as to the ocean as economic fishers but due to the historic and current economic climate needs to make ends meet with other activities.
Saldanha	19/08/2022	Kevin Maart Magdalena Vertyb Magrieta Petro	Aikonese Cochoqua Khoi Tribal Council	• Mr Maart explained the regional extent of the Cochoqua and linkages with the various sub-clans • The historic impact on the decline of fisheries on the community and way of live was discussed • The fear of the impact on the ocean and fish stock by current seismic projects was expressed • They further expanded on the potential impact of the project on their social discourse and how it will further erode their social and cultural way of live.
Houtbaai	20/08/2022	Bradley van Sitters	=Girokamilaas	• The discussion with the interlocuters started off with Mr van Sitters giving a short background of the cultural and economic position of their group in Houtbaai.

		Basil van der Boss Chief Regan James Natahsa James Elston Gillan	Katz Korana Royal House	• It was explained that their people and Korana/Kora House are historically linked to the Cape and West Coast area and the various tribal and cultural groupings can be linked to the original tribes found at the start of colonial power visiting the Cape region and see them as one of the first nations of South Africa • Mr van Sitter explained that they as tribal grouping has a very close spiritual and cultural relation with the ocean and seashores. He further explained that they are reclaiming this historical and ancient linkage. • Although Government is slow in recognising the first people formally, however historically the proof of their existence is there. • They as first and indigenous people have a responsibility as custodians of the environment to speak out against development and activities that will impact on the environment. • They further expanded that their main concerns are the economic impact due to the seismic projects that will just compound the historic economic decline experience by their community. • Chief James explained that they have already seen the impact of seismic activities on fishing stock. • They have also not previously been engaged by government on such projects. They further feel the Government has already sold out on communities where resources are found with no real positive impact back to the communities. • Social decline and cultural loss due to economic decline in the last twenty years will be indicative of the next twenty years.

7 HERITAGE STATEMENT

One of the main issues raised by the communities interacted with during the Public Meetings is the lack of consultation within the communities to hear their concerns. This interaction needs to be at a level that is understood by the local community. This is further strengthened by the indigenous groupings emphasising the need for FPIC. One of the main tasks of this report is to address this lack of consultation through interacting with key groups and individuals and recognising their concerns.

It must be noted that, first and foremost, a large section of the affected communities not only view them as small-scale fishers but also as indigenous people and, as such, are intrinsically linked to the ocean and the land they have lived on centuries. The resurgence movement through which Khoi and San descendants are reclaiming their identity has in recent decades afforded these communities the ability to re-establish their cultural roots and grounding in an ancient landscape. This sentiment is echoed in the founding affidavit submitted (5 Feb 2022) during the appeal submitted to the first Searcher application by CJ Adams. It notes that the ocean is not only important for fishing but also has spiritual meaning and is a place of healing and holds healing powers for the indigenous communities. It further expanded that the ocean and its resources play an important part in their community's history and heritage.

Community identity and culture are thus strongly linked to the ocean and what it can provide, physically and spiritually. Communities have coexisted with the ocean for generations. This existence has created a culture and heritage that defines their way of living, community, and kinship unique to the West Coast of South Africa. Cook (2001) describes this as maritimity, a process whereby the sum of cultural adaptations made by coastal populations becomes imbued with meaning and culture. This is evident in community structures, cultural events, and seasonal activities. Their culture and heritage historically had a physical manifestation in village layouts, boat building and the unique west coast architectural vernacular. This vernacular was appropriated by the rich to develop quasi-cultural village expressions in the modern expansions of West Coast towns such as Paternoster

This uptake of the cultural heritage manifestations or elements of the indigenous communities by the public at large, provides a manner of legitimacy to their culture that is deeply entwined with the ocean and coastal landscape. It, unfortunately, does not translate into economic providence and brings no relief to their plight as subsistence communities. The changes in the fishing economies around the South African coast in the past four decades have resulted in a loss in income and livelihoods. It has inevitably impacted their community structures and activities which are a large part of their cultural heritage.

The public meetings and focused discussions with interlocutors have shown that these communities and groupings are struggling economically due to decades of turmoil in the fishing

industry. An industry plagued by the closing of fish processing plants, fishing licence and quota issues, and diminishing catches due to environmental and industrial impacts, to name a few. This economic downturn led to social issues within the communities. Foremost are poverty, loss of social fabric, substance abuse, teenage pregnancies, and violence. In all the interviews, the above issues were raised as central to their social existence and community experience.

Considering the Article 8(j) and 10(c) Convention on Biological Diversity (29 December 1993), of which South Africa has been a signatory since 1995, the need to "*...respect, preserve and maintain knowledge, innovations and practices of indigenous and local communities embodying traditional lifestyles relevant for the conservation and sustainable use of biological diversity and promote their wider application with the approval and involvement of the holders of such knowledge, innovations and practices and encourage the equitable sharing of the benefits arising from the utilization of such knowledge, innovations and practices*" must be considered within the available South African legislation. As such, the NHRA (section 3) (2)) considers heritage resources that are part of the national estate to include:

- "places to which oral traditions are attached or which are associated with living heritage;
- Or as per subsection 3, has cultural significance or other special values because of –
    a) its importance in the community or pattern of South Africa's history;
    b) its possession of uncommon, rare or endangered aspects of South Africa's natural or cultural heritage;
    c) its potential to yield information that will contribute to an understanding of South Africa's natural or cultural heritage;
    d) its importance in demonstrating the principal characteristics of a particular class of South Africa's natural or cultural places or objects;
    e) its importance in exhibiting particular aesthetic characteristics valued by a community or cultural group;
    f) its importance in demonstrating a high degree of creative or technical achievement at a particular period;
    g) its strong or special association with a particular community or cultural group for social, cultural or spiritual reasons;
    h) its strong or special association with the life or work of a person, group or organisation of importance in the history of South Africa;

As with Smith (2015), Loulanksi (2006), and Ndoro (2105) emphasised that culture is more than just the tangible but is also shared beliefs, values, language, traditions, functionality, meaning and community connections. Considering the various values and heritage significance as listed in section 3(3) of the NHRA, the cultural and living heritage associated with the communities and indigenous people along the southwestern and west coast of South Africa holds heritage significance. It is part of the national estate and holds importance as a way of life for small-scale fishers and Khoisan descendants alike. The physical and spiritual interaction with the ocean and

JUS

the shorelines through millennia resulted in a maritimity that developed into the cultural fabric as they experience it today.

The significance of such intangible and living cultural heritage features can potentially have a combined heritage grading of Grade II or even Grade I through further research. However, grading inevitably implies the investigation into and consideration of a Provincial or Heritage declaration of significance for a largely intangible cultural heritage. This is problematic as the NHRA provides for the proclamation/declaration of place, objects, or structures as Provincial or National Heritage Sites and only refers to intangible/living heritage relating to such place, objects, or structures.

8 IMPACT STATEMENT

The impact assessment rating is based on the rating scale in **Appendix B**

The cultural heritage and living heritage related to the communities linked to fisheries and ocean subsistence and further identifying as indigenous communities can potentially be impacted by the proposed project. This impact is indirect and is in the community perceived to be primarily linked to their economic existence as a result in the loss of fishing yield. Investigation and discussion have shown that the historic economic decline of fisheries has resulted in the loss of social cohesion, activities, and traditions.

To deliberate the potential impact, we evaluated the Commercial and Small-scale Fisheries report completed by Capricorn Marine Environmental (2022) for the Searcher application as well as the Biodiversity and Ecosystem Services Assessment repon (2022) completed for this application completed by Pisces Environmental Services (Pty) Ltd.

The Capricorn report summarises that "***With the implementation of the project controls and mitigation measures, the residual impact due to seismic noise is considered to be of LOW negative significance for the large pelagic longline sector. Due to the remote location of the proposed survey area, noise would be expected to attenuate to below threshold levels before reaching fishing grounds of all other sectors viz. the demersal trawl, midwater trawl, demersal longline, tuna pole-line, small pelagic purse-seine, traditional linefish, west coast rock lobster and small-scale fisheries sectors.***"

The Pisces (2002) survey notes, "***The proposed exploration activities to be undertaken by TGS are expected to result in impacts on marine invertebrate fauna in the Orange Basin, ranging from negligible to very low significance. Only in the case of potential impacts to turtles and marine mammals are impacts of low significance expected.***"

The scientific studies conducted for this project thus identified impacts on fishing stock as low for all types species.

By inference, a potential impact on fishing yield could be expected and thus potential economic impact on communities due to reduced caught fish volumes.

We considered that the recommended mitigation measures, as listed in the specialist reports for the project, focus on the reduction of impacts on fish species and the projected reduction of the impact on the commercial and small-scale fishery catch yield. These mitigation measures should then indirectly positively impact the potential negative impacts on the cultural heritage of the communities to be impacted.

By using the impact assessment methodology as provided by EIMS, we can project a pre-mitigation negative impact on a regional scale over the long term with a moderate intensity due to the potential indirect impact on the communities and, ultimately, their heritage, with a high probability of this impact occurring. The pre-mitigation impact on heritage resources is rated as MEDIUM. The potential residual impact on heritage resources, with mitigation measures from the scientific studies is projected as LOW with a medium confidence factor.

8.1 CUMULATIVE IMPACTS

This section evaluates the possible cumulative impacts (IC) on heritage resources concerning the current application and other proposed applications that are ongoing in the Orange Basin.

The following must be considered in the analysis of the cumulative effect of development on heritage resources:

- **Fixed datum or dataset:** There is no comprehensive heritage data set for the Offshore and onshore impact region and thus we cannot quantify how much of a specific cultural heritage element is present in the region. The region has never been covered by a heritage resources study that can account for all heritage resources. Further to this, none of the heritage studies conducted can with certainty state that all heritage resources within the study area has been identified and evaluated;
- **Defined thresholds:** The value judgement on the significance of a heritage site will vary from individual to individual and between interest groups. Thus, implicating that heritage resources' significance can and does change over time. And so, will the tipping threshold for impacts on a certain type of heritage resource;
- **Threshold crossing:** In the absence of a comprehensive dataset or heritage inventory of the entire region we will never be able to quantify or set a threshold to determine at what

5628

stage the impact from developments on heritage resources has reached or is reaching the danger level or excludes the new development on this basis. (Godwin, 2011)

PGS is, however, aware of the current Searcher application and the potential of another application soon occurring in the Orange Basin. Communities have expressed a definite concern about the multiple application occuring in their fishing waters and the potential long-term effect of these surveys resulting in Oil and Gas companies starting applications for production rights based on the findings of these reconnaissance surveys. ***It is, however, the understanding that only one 3D survey will be done in the overlapping areas even if the various applications are successful over the same area.***

The scientific studies conducted for seismic projects in the same are make the following comments relating to cumulative impacts:

- **Capricorn Marine – Commercial and Small-Scale Fisheries report (2022)**
  Concurrent activities such as other planned speculative or proprietary seismic surveys in the Orange Basin could add to the cumulative impact on fisheries, especially if the activities are concurrent. The cumulative impact on any one fishery is expected to be of VERY LOW to LOW significance. Once completed there is not expected to be any residual impact. This would thus further mitigate any cumulative impact across fishery sectors. The potential that cumulative impacts of other hydrocarbon exploration activities on the fishing industry arise is considered to be possible to likely.
- **Fiona Environmental Services – Biodiversity and Ecosystem Services Assessment for the Searcher and TGS applications (2022)**
  While it is foreseeable that further exploration and future production activities could arise if the current Environmental Clearance Certificate is granted, there is not currently sufficient information available to make reasonable assertions as to nature of such future activities. This is primarily due to the current lack of relevant geological information, which the proposed exploration process aims to address. While there are many other rights holders in the South African offshore environment, most of these are not undertaking any exploration activities at present or would be concurrently with the proposed 3D survey, particularly not in the far offshore environment. Thus, the possible range of the future prospecting, mining, exploration, and production activities that could arise will vary significantly in scope, location, extent, and duration depending on whether a resource(s) is discovered, its size, properties, and location, etc. As these cannot at this stage be reasonably defined, it is not possible to undertake a reliable assessment of the potential cumulative environmental impacts. It is also possible that the proposed, or future, exploration fails to identify an economic petroleum resource, in which case the potential impacts associated with the production phase would not be realised.

The report further notes that..."*Similarly, potential cumulative impacts on individuals and populations as a result of other seismic surveys undertaken either previously, concurrently or subsequently are difficult to assess.*'

- **Pisces Environmental Services – Biodiversity and Ecosystem Services Assessment for the TGS applications (2022)**
  While it is foreseeable that further exploration and future production activities could arise if the current Environmental Authorisation is granted, there is not currently sufficient information available to make reasonable assertions as to nature of such future activities. This is primarily due to the current lack of relevant geological information, which the proposed exploration process aims to address. There are many other rights holders in the South African and adjacent Namibian offshore environment, but most of these are not undertaking any exploration activities at present or would be concurrently with the proposed 3D survey, particularly not in the far offshore environment. Thus, the possible range of the future prospecting, mining, exploration and production activities that could arise will vary significantly in scope, location, extent, and duration depending on whether a resource(s) is discovered, its size, properties and location, etc. As these cannot at this stage be reasonably defined, it is not possible to undertake a reliable assessment of the potential cumulative environmental impacts. It is also possible that the proposed, or future, exploration fails to identify an economic petroleum resource, in which case the potential impacts associated with the production phase would not be realised...

  ...Other than this project, there are currently three other applications for 3D surveying being prepared over much the same area of the Deep Water Orange Basin. Should these all be approved, it is, however, highly unlikely that the operators will undertake these surveys either concurrently or sequentially. This again emphasises that the number of applications submitted to PASA cannot be assumed to relate to a realistic assessment of cumulative impacts.

At this stage, cumulative impacts are purely speculative. Still, the potential for the future increase in cumulative impacts due to current and future seismic surveys and the potential for future Oil and Gas production cannot be excluded but is not quantifiable at this stage for cultural heritage.

Table 6 - Impact table

IMPACT (HAZARD/RISK)		Pre-Mitigation							Post Mitigation										
Impact	Phase	Nature	Extent	Duration	Magnitude	Reversibility	Probability	Pre-mitigation SR	Nature	Extent	Duration	Magnitude	Reversibility	Probability	Post-mitigation SR	Confidence	Significance Impact	Implementation Cost	Priority Factor	Final score
Impact on cultural heritage	Overall	-1	4	4	3	3	4	-14	-1	4	3	1	3	1	4.25	Medium	1	1	1.13	-8.25

9 CONCLUSIONS AND RECOMMENDATIONS

The background research and initial public participation in the available consultation days given to PGS have shown that the affected communities are largely linked to subsistence and small-scale fisheries along the west coast of the Western and Northern Cape Provinces of South Africa.

These communities have expressed their concerns about the effect that the proposed 3D reconnaissance project will have on the fishing stock that will ultimately impact their livelihoods. It is also evident that they do not place much faith in the findings of the scientific fishing stock studies for this and other similar projects.

9.1 HERITAGE STATEMENT SUMMARY

It must be noted that, first and foremost, a large section of the affected communities not only view them as small-scale fishers but also as indigenous people and, as such, are intrinsically linked to the ocean and the land they have lived on centuries. The resurgence movement through which Khoi and San descendants are reclaiming their identity has in recent decades afforded these communities the ability to re-establish their cultural roots and grounding in an ancient landscape. This sentiment is echoed in the founding affidavit submitted (5 Feb 2022) during the appeal submitted to the first Searcher application by CJ Adams. It notes that the ocean is not only important for fishing but also has spiritual meaning and is a place of healing and holds healing powers for the indigenous communities. It further expanded that the ocean and its resources play an important part in their community's history and heritage.

Community identity and culture are thus strongly linked to the ocean and what it can provide, physically and spiritually. Communities have coexisted with the ocean for generations. This existence has created a culture and heritage that defines their way of living, community, and kinship unique to the West Coast of South Africa. Cook (2001) describes this as maritimity, a process whereby the sum of cultural adaptations made by coastal populations becomes imbued with meaning and culture. This is evident in community structures, cultural events, and seasonal activities.

The public meetings and focused discussions with interlocutors have shown that these communities and groupings are struggling economically due to decades of turmoil in the fishing industry. An industry plagued by the closing of fish processing plants, fishing licence and quota issues, and diminishing catches due to environmental and industrial impacts, to name a few. This economic downturn led to social issues within the communities. Foremost are poverty, loss of social fabric, substance abuse, teenage pregnancies, and violence. In all the interviews, the above issues were raised as central to their social existence and community experience.

As with Smith (2015), Loulanksi (2006), and Ndoro (2105) emphasised that culture is more than just the tangible but is also shared beliefs, values, language, traditions, functionality, meaning and community connections. Considering the various values and heritage significance as listed in section 3(3) of the NHRA, the cultural and living heritage associated with the communities and indigenous people along the southwestern and west coast of South Africa holds heritage significance. It is part of the national estate and holds importance as a way of life for small-scale fishers and Khoisan descendants alike. The physical and spiritual interaction with the ocean and the shorelines through millennia resulted in a maritimity that developed into the cultural fabric as they experience it today.

The significance of such intangible and living cultural heritage features can potentially have a combined heritage grading of Grade II or even Grade I through further research. However, grading inevitably implies the investigation into and consideration of a Provincial or Heritage declaration of significance for a largely intangible cultural heritage. This is problematic as the NHRA provides for the proclamation/declaration of place, objects, or structures as Provincial or National Heritage Sites and only refers to intangible/living heritage relating to such place, objects, or structures.

9.2 IMPACT STATEMENT SUMMARY

The scientific studies conducted for this project identified impacts on fishing stock as low for all species.

By inference, a potential impact on fishing yield could be expected and thus potential economic impact on communities due to reduced caught fish volumes.

We considered that the recommended mitigation measures, as listed in the specialist reports for the project, focus on the reduction of impacts on fish species and the projected reduction of the impact on the commercial and small-scale fishery catch yield. These mitigation measures should then indirectly positively impact the potential negative impacts on the cultural heritage of the communities to be impacted.

By using the impact assessment methodology as provided by EIMS, we can project a pre-mitigation negative impact on a regional scale over the long term with a moderate intensity due to the potential indirect impact on the communities and, ultimately, their heritage, with a high probability of this impact occurring. The pre-mitigation impact on heritage resources is rated as MEDIUM. The potential residual impact on heritage resources, with mitigation measures from the scientific studies, is projected as LOW with a medium confidence factor.

aware of the current Searcher application and the potential of another application soon occurring in the Orange Basin. Communities have expressed a definite concern about the multiple application occuring in their fishing waters and the potential long-term effect of these surveys resulting in Oil and Gas companies starting applications for production rights based on the findings of these reconnaissance surveys. It is, however, the understanding that only one 3D survey will be done in the overlapping areas even if the various applications are successful over the same area.

At this stage, cumulative impacts are purely speculative. Still, the potential for the future increase in cumulative impacts due to current and future seismic surveys and the potential for future Oil and Gas production cannot be excluded but is not quantifiable at this stage for cultural heritage.

9.3 RECOMMENDATIONS

The following recommendations are based on the UNESCO ICH guidelines. They are aimed at safeguarding the cultural heritage of the small-scale fishers and cultural groupings in the influence of this project:

- Re-assess post-project the potential effects on the identified communities and their intangible cultural heritage. This will require consideration of the socio-economic baseline developed during this environmental impact process against quantified economic damage and losses and human development impacts in a follow-up socio-economic. It will enable the heritage specialist to evaluate the link between the socio-economic changes induced by the proposed project as it relates to changes in the intangible cultural heritage practices of the communities.
- Based on the outcomes, **provide resources and support for communities** to develop and undertake safeguarding measures or plans to enhance the **mitigation capacity of their intangible cultural heritage by fostering dialogue, mutual understanding and reconciliation** between and within communities.
- It is anticipated that this can be achieved through the implementation of the mitigation measures in the Social Impact Assessment.

We know that 3D seismic surveys can locate wrecks on the surface, and sometimes below sediments. Any shipwrecks or pieces thereof noted during the survey must be shared with the SAHRA MUCH Unit for inclusion into the national database. These could then be identified and be incorporated into the EMP.

Considering the assessment based on the findings of the fieldwork as well as the scientific studies relating to the impact on fisheries, I am of the opinion that the impact of the proposed project on

the intangible cultural heritage resources and practices can be mitigated through the implementation of the recommendations in this report.

APPENDIX A

ENVIRONMENTAL IMPACT METHODOLOGY

The impact significance rating methodology, as provided by EIMS, is guided by the requirements of the NEMA EIA Regulations 2014 (as amended). The broad approach to the significance rating methodology is to determine the environmental risk (ER) by considering the consequence (C) of each impact (comprising Nature, Extent, Duration, Magnitude, and Reversibility) and relate this to the probability/ likelihood (P) of the impact occurring. This determines the environmental risk. In addition, other factors, including cumulative impacts and potential for irreplaceable loss of resources, are used to determine a prioritisation factor (PF) which is applied to the ER to determine the overall significance (S). The impact assessment will be applied to all identified alternatives. Where possible, mitigation measures will be recommended for the impacts identified.

10.4 DETERMINATION OF ENVIRONMENTAL RISK

The significance (S) of an impact is determined by applying a prioritisation factor (PF) to the environmental risk (ER). The environmental risk is dependent on the consequence (C) of the impact and the probability (P) of the impact occurring. The consequence is determined through the consideration of the Nature (N), Extent (E), Duration (D), Magnitude (M), and reversibility (R) applicable to the specific impact.

To this methodology, the consequence of the impact is represented by:

$$C = \frac{(E+D+M+R) \times N}{4}$$

Each individual aspect in the determination of the consequence is represented by a rating scale as defined in **Table 7** below.

Table 7 – Criteria for Determining Impact Consequence

Aspect	Score	Definition
Nature	-1	Likely to result in a negative/ detrimental impact
	+1	Likely to result in a positive/ beneficial impact
Extent	1	Activity (i.e. limited to the area applicable to the specific activity)
	2	Site (i.e. within the development property boundary).
	3	Local (i.e. the area within 5 km of the site).
	4	Regional (i.e. extends between 5 and 50 km from the site
	5	Provincial / National (i.e. extends beyond 50 km from the site)
Duration	1	Immediate (<1 year)
	2	Short term (1-5 years).
	3	Medium term (6-15 years).
	4	Long term (the impact will cease after the operational life span of the project).

Aspect	Score	Definition
	5	Permanent (no mitigation measure of natural process will reduce the impact after construction).
Magnitude/ Intensity	1	Minor (where the impact affects the environment in such a way that natural, cultural and social functions and processes are not affected).
	2	Low (where the impact affects the environment in such a way that natural, cultural and social functions and processes are slightly affected).
	3	Moderate (where the affected environment is altered but natural, cultural and social functions and processes continue albeit in a modified way).
	4	High (where natural, cultural or social functions or processes are altered to the extent that it will temporarily cease). or
	5	Very high / don't know (where natural, cultural or social functions or processes are altered to the extent that it will permanently cease).
Reversibility	1	Impact is reversible without any time and cost.
	2	Impact is reversible without incurring significant time and cost.
	3	Impact is reversible only by incurring significant time and cost.
	4	Impact is reversible only by incurring prohibitively high time and cost.
	5	Irreversible impact

Once the C has been determined, the ER is determined in accordance with the standard risk assessment relationship by multiplying the C and the P. Probability is rated/ scored as per Table 8.

Table 8 - Probability Scoring

Probability	1	Improbable (the possibility of the impact materialising is very low as a result of design, historic experience, or implementation of adequate corrective actions; <25%).
	2	Low probability (there is a possibility that the impact will occur; >25% and <50%).
	3	Medium probability (the impact may occur; >50% and <75%).
	4	High probability (it is most likely that the impact will occur- > 75% probability). or
	5	Definite (the impact will occur)

The result is a qualitative representation of relative ER associated with the impact. ER is therefore calculated as follows:

ER= C x P

Table 9 - Determination of Environmental Risk

Consequence	5	5	10	15	20	25
	4	4	8	12	16	20
	3	3	6	9	12	15
	2	2	4	6	8	10
	1	1	2	3	4	5
	0	1	2	3	4	5
	Probability					

The outcome of the environmental risk assessment will result in a range of scores, ranging from 1 through to 25. These ER scores are then grouped into respective classes as described in Table 10.

Table 10 - Significance Classes

Environmental Risk Score	
Value	**Description**
<9	Low (i.e., where this impact is unlikely to be a significant environmental risk).
≥9 - <17	Medium (i.e., where the impact could have a significant environmental risk).
≥17	High (i.e., where the impact will have a significant environmental risk).

The impact ER will be determined for each impact without relevant management and mitigation measures (pre-mitigation), as well as post-implementation of relevant management and mitigation measures (post-mitigation). This allows for a prediction in the degree to which the impact can be managed/mitigated.

10.5 IMPACT PRIORITISATION

Further to the assessment criteria presented in the section above, it is necessary to assess each potentially significant impact in terms of:

1. Cumulative impacts; and
2. The degree to which the impact may cause irreplaceable loss of resources.

To ensure that these factors are considered, an impact prioritisation factor (PF) will be applied to each impact ER (post-mitigation). This prioritisation factor does not aim to detract from the risk ratings but rather to focus the attention of the decision-making authority on the higher priority/significance issues and impacts. The PF will be applied to the ER score based on the assumption that relevant suggested management/mitigation impacts are implemented.

Table 11 - Criteria for Determining Prioritisation

Cumulative Impact (CI)	Low (1)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is unlikely that the impact will result in spatial and temporal cumulative change.
	Medium (2)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is probable that the impact will result in spatial and temporal cumulative change.
	High (3)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/ definite that the impact will result in spatial and temporal cumulative change.
Irreplaceable Loss of Resources (LR)	Low (1)	Where the impact is unlikely to result in irreplaceable loss of resources
	Medium (2)	Where the impact may result in the irreplaceable loss (cannot be replaced or substituted) of resources but the value (services and/or functions) of these resources is limited.

	High (3)	Where the impact may result in the irreplaceable loss of resources of high value (services and/or functions).

The value for the final impact priority is represented as a single consolidated priority, determined as the sum of each individual criteria represented in Table 12. The impact priority is therefore determined as follows:

Priority = CI + LR

The result is a priority score which ranges from 3 to 9 and a consequent PF ranging from 1 to 2 (Refer to Table 12).

Table 12 - Determination of Prioritisation Factor

Priority	Ranking	Prioritisation Factor
2	Low	1
3	Medium	1.125
4	Medium	1.25
5	Medium	1.375
6	High	1.5

To determine the final impact significance, the PF is multiplied by the ER of the post-mitigation scoring. The ultimate aim of the PF is an attempt to increase the post-mitigation environmental risk rating by a full ranking class if all the priority attributes are high (i.e., if an impact comes out with a medium environmental risk after the conventional impact rating, but there is significant cumulative impact potential and significant potential for irreplaceable loss of resources, then the net result would be too upscale the impact to a high significance).

Table 13 - Final Environmental Significance Rating

Environmental Significance Rating	
Value	**Description**
< -17	High negative (i.e., where the impact must have an influence on the decision process to develop in the area).
≥ -17 ≤ -9	Medium negative (i.e., where the impact could influence the decision to develop in the area).
> -9, <0	Low negative (i.e., where this impact would not have a direct influence on the decision to develop in the area).
0	No impact
<0, <9	Low positive (i.e., where this impact would not have a direct influence on the decision to develop in the area).
≥ 10 ≤ 17	Medium positive (i.e., where the impact could influence the decision to develop in the area).
≥ 217	High positive (i.e., where the impact must have an influence on the decision process to develop in the area).

The significance ratings and additional considerations applied to each impact will be used to provide a quantitative comparative assessment of the alternatives being considered. In addition, professional expertise and opinion of the specialists and the environmental consultants will be applied to provide a qualitative comparison of the alternatives under consideration. This process will identify the best alternative for the proposed project.

APPENDIX B

PGS TEAM CVS

WOUTER FOURIE

Professional Heritage Specialist and Professional Archaeologist and Director PGS Heritage

Summary of Experience

Specialised expertise in Archaeological Mitigation and excavations, Cultural Resource Management and Heritage Impact Assessment Management, Archaeology, Anthropology, Applicable survey methods, Fieldwork and project management, Geographic Information Systems, including *inter alia* -

Involvement in various grave relocation projects (some of which relocated up to 1000 graves) and grave "rescue" excavations in the various provinces of South Africa

Involvement with various Heritage Impact Assessments, within South Africa, including -

- Archaeological Walkdowns for various projects
- Phase 2 Heritage Impact Assessments and EMPs for various projects
- Heritage Impact Assessments for various projects
- Iron Age Mitigation Work for various projects, including archaeological excavations and monitoring
- Involvement with various Heritage Impact Assessments, outside South Africa, including -
- Archaeological Studies in Democratic Republic of Congo
- Heritage Impact Assesements in Mozambique, Botswana, and DRC
- Grave Relocation project in DRC

Key Qualifications

BA [Hons] (Cum laude) - Archaeology and Geography - 1997

BA - Archaeology, Geography and Anthropology - 1996

Professional Archaeologist - Association of Southern African Professional Archaeologists (ASAPA) - Professional Member

Accredited Professional Heritage Specialist – Association of Professional Heritage Practitioners (APHP)

CRM Accreditation (ASAPA) -

- Principal Investigator - Grave Relocations
- Field Director – Iron Age
- Field Supervisor – Colonial Period and Stone Age
- Accredited with Amafa KZN

Key Work Experience

2009- current - Director – Professional Grave Solutions (Pty) Ltd

2007 – 2009 - Project Manager – Marakoma-ARM, Heritage Contracts Unit, University of the Witwatersrand

JGS

2005-2007 - Director – Matakoma Heritage Consultants (Pty) Ltd

2000-2004 - CEO– Matakoma Consultants

1998-2000 - Environmental Coordinator – Randfontein Estates Limited, Randfontein, Gauteng

1997-1998 - Environmental Officer – Department of Minerals and Energy, Johannesburg, Gauteng

Worked on various heritage projects in the SADC region including, Botswana, Mauritius, Malawi, Zambia, Mozambique, and the Democratic Republic of the Congo

PROFESSIONAL CURRICULUM VITAE FOR NIKKI MANN

Key Qualifications:

MSc Archaeology (phytolith analysis) - University of Cape Town - 2017
BSc Honours Archaeology - University of Cape Town – 2014
Bachelor of Science (BSc) - University of Cape Town - Majors in Archaeology, and Environmental and Geographical Science -2013

Professional Archaeologist – Association of Southern African Professional Archaeologists **(ASAPA)**

Archaeological Experience

- 2021- Current – Archaeologist – PGS Heritage (Pty) Ltd
- Kathu Tyre Management Plant HIA. Kathu. EXM. Position: Heritage Specialist.
- Kathu Borrow Pit Screening. Kathu. EXM. Position: Heritage Specialist.
- Harmony Karee:and Pipelines Project. Between Klerkdorp and Potchefstroom, North West Province. EIMS. Position: Heritage Specialist
- Black Mountain PV, Northern Cape. Uvuna. Position: Heritage Specialist
- Proposed amendment of existing mining activities for Kolomela Mine. South-west of Postmasburg, Northern Cape. EXM. Position: Heritage Specialist.
- Proposed amendment of existing mining activities for Kudumane Mine. Hotazel, Northern Cape. SRK. Position: Heritage Specialist.
- Victoria West Pipeline project. Victoria West. IXEng. Position: Heritage Specialist.
- Koup 1 and Koup 2 WEF. Beaufort West, Western Cape. SIVEST. Position: Heritage Specialist.
- Victoria West Pipelines. Victoria West, Northern Cape. IXEng. – Position: Heritage Specialist.
- East Orchards Poultry Farm Project. Delmas, Mpumalanga. EcoSphere. – Position: Heritage Specialist.
- Phase 1 Archaeological Impact Assessment (Phase 1 AIA): Gunstfontein Wind Energy Facility (WEF) and overhead powerline, near Sutherland, Northern Cape, South Africa. – Position: Archaeological Specialist (November 2020).
- Phase 1 Archaeological Impact Assessment (Phase 1 AIA): Proposed development of an overhead powerline for the approved Oya PV Facility, between Sutherland and Matjiesfontein, Northern and Western Cape, South Africa. – Position: Archaeological Specialist (October 2020).
- Phase 1 Archaeological Impact Assessment (Phase 1 AIA): Proposed development of infrastructure for the approved Kudusberg Wind Energy Facility (WEF), between Sutherland and Matjiesfontein, Northern and Western Cape, South Africa. – Position: Archaeological Specialist (October 2020).
- Phase 1 Archaeological Impact Assessment (Phase 1 AIA): Proposed Square Kilometre Array (SKA) fibre optic cable, between Beaufort West and Carnarvon, Northern and Western Cape, South Africa. (September 2020).
- Phase 1 Archaeological Impact Assessment (**Phase 1 AIA**): Kolkies PV (Photovoltaics) Project, north of Touws River, Western Cape, South Africa. – Position: Archaeological Specialist (September 2020).
- Phase 1 Archaeological Impact Assessment (**Phase 1 AIA**): Plenaarspoort Wind Energy Facility (WEF) Project 1 and 2, north-west of Matjiesfontein, Western Cape, South Africa. – Position: Archaeological Specialist (September 2020).
- Phase 1 Archaeological Impact Assessment (**Phase 1 AIA**): Swellendam Wind Energy Facility (WEF), Swellendam, Western Cape, South Africa. – Position: Archaeological Specialist (August 2020).

- **Phase 2 Archaeological Mitigation**: Proposed development of infrastructure in the Port of Ngqura within the Coega Industrial Development Zone (IDZ), Nelson Mandela Bay Municipality, Eastern Cape, South Africa: Contract Archaeologist, excavation of Later Stone Age (LSA) shell middens (July 2020). Contracted to work with PGS Heritage.
- Polihali Dam Heritage Management Project, Lesotho: Junior field archaeologist, excavation of Later Stone Age (LSA) sites (May 2019- May 2020) as part of PGS Heritage.
  - Duties included excavation of rock shelters, site supervision, site recording, photography, lab work, section drawing and digital illustration (Inkscape and Photoshop), assisting in report writing and implementation of HSE practices.
- Ledi-Geraru Research Project, Ethiopia: excavation of Early Stone Age (ESA) sites (February-March 2020; Directed by Dr David R. Braun)
- Gorras Farm, Northern Cape, South Africa: excavation of middens next to a corbelled building; Historical site (October 2018; supervised by Simon Lee Hall and UCT PhD student Ms Vuyiswa Thembelihle Lupuwana)
  - Duties included excavation of middens and surface collection.
- **Phase 2 Archaeological Mitigation**: Proposed development of boreholes and associated pipelines for the Langebaan Aquifer within the Hopefield Private Nature Reserve, Hopefield, Western Cape. - Position: Archaeological specialist (August 2018).
- Koobi Fora Field School, Kenya: Intern, excavation of Early Stone Age (ESA) and Middle Stone Age (MSA) sites (June-July 2018; Directed by Dr David R. Braun, Kathryn Ranhorn (Postdoctoral Research Fellow at Harvard University) and Jonathan Reeves (PhD student at The George Washington University))
- Data extraction to SAHRIS (South African Heritage Resource Agency) for CTS Heritage (April 2018)
- Phase 1 Archaeological Impact Assessment (**Phase 1 AIA**). Matjiesfontein Road Extension Project, Matjiesfontein, Western Cape. – Position: Archaeological Specialist (April 2018).
- Ledi-Geraru Research Project, Ethiopia: excavation of Early Stone Age (ESA) sites (February-March 2018; Directed by Dr David R. Braun)
- Ferrycarrig, Irish National Heritage Park, Wexford, southeast Ireland: Excavation of ringwork castle site associated with the Anglo-Norman invasion of Ireland (January 2018; Directed by Dr Denis Shine and Dr Stephen Mandal)

DECLARATION OF THE ENVIRONMENTAL SPECIALIST

I, Wouter Fourie declare that –

General declaration:

- I act as an independent specialist in this application.
- I will perform the work relating to the application in an objective manner, even if this results in views and findings that are not favorable to the applicant.
- I declare that there are no circumstances that may compromise my objectivity in performing such work.
- I have expertise in conducting undertaking the specialist work as required, including knowledge of the Act, Regulations and any guidelines that have relevance to the proposed activity.
- I will comply with the Act, Regulations, and all other applicable legislation.
- I have not, and will not engage in, conflicting interest in the undertaking of the activity.
- I understand to disclose to the applicant and competent authority all material information in my possession that reasonably has or may have the potential of influencing- any decision to be taken with respect to the application by the competent authority; and the objectivity of any report, plan or document to be prepared by myself for submission to the competent authority.
- I have taken into account, to the extent possible, the matters referred to in Regulation 18 when preparing the report, plan or document.
- I will provide the competent authority with access to all information at my disposal regarding the application, whether such information is favourable to the applicant or not.
- All the particulars furnished by me this form are true and correct.
- I will perform all other obligations as expected from an environmental assessment practitioner in terms of the Regulations.
- I am aware of what constitutes an offence in terms of Regulation 48 and that a person convicted of an offence in terms of Regulation 48(1) is liable to the penalties as contemplated in Section 49B of the Act.

Disclosure of Vested Interest

I do not have and will not have any vested interest (either business, financial, personal or other) in the proposed activity proceeding other than remunerative for work performed in terms of the Regulations.

Signature of the Specialist:

Name of Company: PGS Heritage Pty Ltd

Date: 5/12/2022

UNDERTAKING UNDER OATH/AFFIRMATION

E-25

I, Wouter Fourie swear under oath/affirm that all the information submitted or to be submitted for the purposes of this application is true and correct.

TGS Orange Basin Reconnaissance Project

Social Impact Assessment

Prepared by:

Equispectives Research & Consulting Services

Contact person: Ms San-Marié Aucamp

Dr Ilse Aucamp

Prepared for:
EIMS

September 2022

Executive Summary

TGS Geophysical Company (UK) Ltd proposes to undertake a 3D seismic survey off the West Coast of South Africa. The proposed project area is located approximately 256 km offshore of St Helena Bay, extending north along the western coastline to approximately 220 km offshore of Hondeklip Bay over a number of petroleum license blocks. At the closest point the proposed survey area is approximately 218 km offshore of the coast of the Western and Northern Cape provinces. The area of interest for the proposed 3D seismic survey is approximately 30 000 km^2 in extent.

TGS's activities for this application would be of short duration if approved, and if viewed in isolation considering only technical risks as discussed in various specialist reports conducted as part of the EIA process, the impacts will be negligible. However, communities feel that there are significant gaps in the available data and from a social perspective the non-technical or social risks can potentially cause significant impacts. The following potential social impacts have been identified:

- Uncertainty
- Further marginalisation of vulnerable groups
- Concerns about cumulative impacts
- Perceived impact on livelihoods
- Impacts on sense and spirit of place
- Impacts on the social licence to operate
- Stakeholder fatigue and disillusionment
- Community expectations
- Social unrest

JRDS

Seismic reconnaissance projects are controversial in South Africa and has been in the news frequently in the last year. For many stakeholders it is an emotional matter, for others the potential of impacting their livelihoods is the biggest fear. There are also stakeholders that feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change. Other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. It is a complex and wicked[1] problem.

Based on the findings, the following recommendations are made:

- TGS should develop a community engagement protocol, communication strategy and grievance mechanism that is based on the San Code of Research Ethics.
- TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. Collaboration across seismic operators with holders of hydrocarbon exploration and the industry as a whole to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study. This would quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in South African Waters.
- Consult with communities on potential ways in which to make a positive contribution to the communities.
- Engage in meaningful consultation.
- The seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign.

[1] a wicked problem is a problem that is difficult or impossible to solve because of incomplete, contradictory, and changing requirements that are often difficult to recognize.

From a social perspective it is clear that the communities and majority of local people are opposed to the project. If the project is considered in isolation, the impacts are negligible. However, the project does not happen in a vacuum, and the social environment is much wider than the footprint of the project. If the social risks and potential damage to cultural and indigenous rights are considered the impact on the social fabric of already vulnerable communities may be significant. At this stage communities feel that they cannot make informed decisions. Communities does not distinguish between the different role players in the seismic survey industry. Although all legal processes have been followed by TGS, the seismic survey industry is not moving at the pace of the community, and in the long run this will be detrimental to the industry. Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed. From a social perspective it is recommended that the project proceed subject to the mitigation measures (i.e. meaningful consultation, local research, education, and awareness raising in the project-affected communities) forming part of the conditions for authorisation and being implemented prior to the commencement of the actual survey.

Opsomming

TGS Geophysical Company (UK) Ltd beoog om 'n 3D seismiese opname te doen aan die Weskus van Suid-Afrika. Die voorgenome projek area is ongeveer 256 km van St Helena Baai in die diepsee geleë, en strek dan Noord teen die westelike kuslyn af tot ongeveer 220 km in die diepsee in vanaf Hondeklipbaai oor 'n aantal petroleum lisensie blokke. Die punt wat die naaste aan die land is, is ongeveer 218 km in die diepsee aan die kus van die Wes Kaap en die Noord Kaap Provinsies. Die gebied wat die voorgenome 3D seismiese opname beplan om te dek beslaan ongeveer 30 000 km^2.

TGS se aktiwiteite vir hierdie aansoek sal van korte duur wees indien dit goedgekeur word, en wanneer dit in isolasie beskou word en slegs die tegniese risiko's oorweeg word soos wat bepreek is in die onderskeie spesialis studies wat gedoen is as deel van die omgewingsimpak assessering proses is die impakte gering. Die betrokke gemeenskappe voel egter dat daar betekenisvolle gapings in die beskikbare data is en van 'n sosiale perspektief kan die nie-tegnies of sosiale risiko's potensieel betekenisvolle impakte veroorsaak. Die volgende sosiale impakte is geïdentifiseer:

- Onsekerheid
- Verdere uitskuiwing van weerbare groepe
- Bekommernisse oor kumulatiewe impakte
- Perceived impak op vermoë om 'n lewensbestaan te maak
- Impakte op sin en gees van plek
- Impakte op die sosiale bedryfslisensie
- Uitputting en ontmugtering van geaffekteerde gemeenskappe (agv volume van konsultasie)
- Verwagtinge van die gemeenskappe

- Maatskaplike onrus

Seismiese verkenningsprojekte is kontroversieel in Suid Afrika en was dikwels in die nuus die afgelope jaar. Vir baie belanghebbendes is dit 'n emosionele saak, vir ander is die moontlikheid dat hulle lewensbestaan geaffekteer gaan word die grootste vrees. Daar is ook belanghebbendes wat voel dat die eksplorasie vir fossielbrandstowwe nie in lyn is met volhoubare ontwikkeling en die stryd teen klimaatsverandering is nie. Ander belanghebbendes voel dat dit noodsaaklik is vir die groei en ontwikkeling van die Suid Afrikaanse ekonomie om betrokke te raak by hierdie ondersoeke. Dit is 'n komplekse probleem, en 'n probleem wat moeilik of onmoontlik is om op te los.

Gebaseer op die bevindinge word die volgende aanbevelings gemaak:

- TGS moet 'n gemeenskapsbetrokkenheid protokol, kommunikasie strategie en grief meganisme ontwikkel wat gebaseer is op die San Kode van Navorsingsetiek.

- TGS moet behulpsaam wees met samewerking tot onafhanklike navorsing oor hoe visspesies aan die Weskus soos snoek reageer op seismiese opnames. Samewerking tussen seismiese operateurs en houers van koolwaterstof eksplorasie regte en die industrie as 'n geheel om kollektief pro-aktiewe navorsing te befonds sal die geleentheid bied vir die ontwikkeling en implementering van 'n gestruktureerd en eksperimenteel solide akoestiese studie. Dit sal die owerhede en belanghebbendes kwantitatief inlig omtrent die akoestiese impakte op die verskeie fauna groepe in die Suid Afrikaanse waters.

- Konsulteer met die gemeenskap op maniere waarop 'n positiewe bydrae tot die gemeenskappe gelewer kan word.

- Raak betrokke by betekenisvolle konsultasie.

- Die seismiese opname bedryf moet hulle posisie en sosiale bedryfslisensie as 'n industrie in die Suid-Afrikaanse konteks heroorweeg en 'n strategiese omgewingsassessering van die impak van die bedryf uitvoer en 'n bewusmakings- en opvoedkundige veldtog van stapel stuur.

Vanuit 'n sosiale perspektief is dit duidelik dat die gemeenskappe en die meerderheid van die plaaslike mense gekant is teen die projek. As die projek in isolasie beskou word, is die impakte gering. Die projek vind egter nie in 'n vakuum plaas nie, en die sosiale omgewing is heelwat breër as die voetspoor van die projek. Indien die sosiale risiko's en potensiële skade aan die kulturele en inheemse regte oorweeg word, kan die impak op die sosiale weefsel van die reeds weerlose gemeenskappe betekenisvol wees. Vanuit 'n sosiale perspektief kan die projek slegs aanbeveel word na betekenisvolle konsultasie, plaaslike navorsing, opvoeding, en bewusmaking gedoen is in die gemeenskappe wat deur die projek geraak is. Tans voel die gemeenskappe dat hulle nie ingeligte besluite kan neem nie. Gemeenskappe onderskei nie tussen die verskillende rolspelers in die seismiese opname industrie nie. Alhoewel al die wetlike prosesse deur TGS gevolg is, beweeg die seismiese opname bedryf nie teen die pas van die gemeenskap nie, en op die lange duur sal dit tot nadeel van die industrie wees. Moontlike toekomstige voordele en ekonomiese ontwikkeling van die land indien die opnames betekenisvolle hulpbronne vind, word nie betwyfel nie. Die aanbeveling is gevolglik dat die projek slegs kan voortgaan sodra die mitigasie maatreëls geïmplementeer is en die gemeenskappe genoegsaam ingelig en toegerus is om op 'n betekenisvolle manier betrokke te raak.

Declaration of Independence

Equispectives Research and Consulting Services declare that:

- All work undertaken relating to the proposed project was done as independent consultants;
- They have the necessary required expertise to conduct social impact assessments, including the required knowledge and understanding of any guidelines or policies that are relevant to the proposed activity;
- They have undertaken all the work and associated studies in an objective manner, even if the findings of these studies were not favourable to the project proponent;
- They have no vested interest, financial or otherwise, in the proposed project or the outcome thereof, apart from remuneration for the work undertaken under the auspices of the above-mentioned regulations;
- They have no vested interest, including any conflicts of interest, in either the proposed project or the studies conducted in respect of the proposed project, other than complying with the relevant required regulations; and
- They have disclosed any material factors that may have the potential to influence the competent authority's decision and/or objectivity in terms of any reports, plans or documents related to the proposed project as required by the regulations.

Record of Experience

Ilse Aucamp and San-Marié Aucamp compiled this report.

Ilse Aucamp holds a D Phil degree in Social Work obtained from the University of Pretoria in 2015. She also has master's degree in environmental management (Cum Laude) from the Potchefstroom University for Christian Higher Education, which she obtained in 2004. Prior to that she completed a BA degree in Social Work at the University of Pretoria. She is frequently a guest lecturer in pre- as well as post-graduate programmes at various tertiary institutions. Her expertise includes social impact assessments, social management plans, social and labour plans, social auditing, training as well as public participation. She is a co-author of the newly published *Social Impact Assessment: Guidance for assessing and managing the social impacts of projects* document published by the International Association for Impact Assessment.

San-Marié Aucamp is a registered Research Psychologist with extensive experience in both the practical and theoretical aspects of social research. She has more than 20 years' experience in social research and she occasionally presents guest lectures on social impact assessment. Her experience includes social impact assessments, social and labour plans, training, group facilitation as well as social and marketing research in a range of sectors such as mining, manufacturing, utilities, government, automotive, financial services, telecoms and IT as well as FMCG. She occasionally presents guest lectures at tertiary institutions. San-Marié is a contributor to the international guidance document on assessing and managing social impacts for projects that was published by IAIA International in 2015. She is currently busy with her PhD in Consulting Psychology.

1 Introduction

TGS Geodata UK Ltd proposes to undertake a 3D seismic survey off the West Coast of South Africa. The proposed project area is located approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay over a number of petroleum license blocks. At the closest point the proposed survey area is approximately 218 km offshore of the coast of the Western and Northern Cape provinces. The area of interest for the proposed 3D seismic survey is approximately 57 400 km^2 in extent.

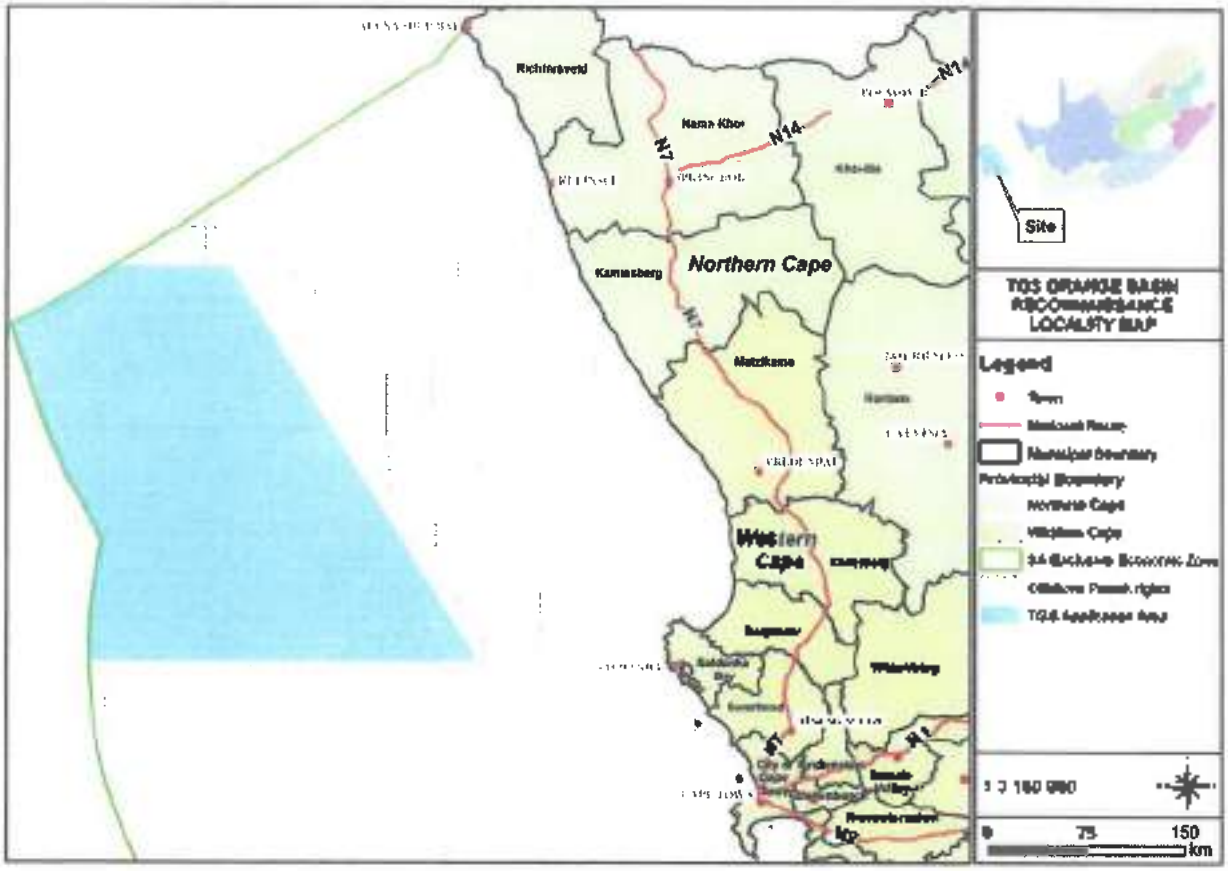
Marine seismic surveys are the primary tool for locating hydrocarbon deposits and are thus a key component of offshore oil and gas exploration. Hydrocarbon deposits occur in reservoirs in sedimentary rock layers. Being lighter than water they accumulate in traps where the sedimentary layers are arched or tilted by folding or faulting of the geological layers. It is currently envisaged that the survey lines would have a NE-SW or a SE-NW orientation. The 3D survey will take in the order of 70 days including downtime.

A single survey vessel equipped with seismic sources and streamers will be used which will be supported by up to two escort vessels. The escort vessel will assist in monitoring for and alerting of other vessels (e.g. fishing, transport, etc) about the survey and the lack of manoeuvrability of the survey vessel. At a minimum one Fisheries Liaison Officer (FLO) that speaks English and Afrikaans will be on board either the survey or escort vessel to facilitate communication in a local language with the fishing or other vessels that are in the area. In addition, there will be Marine Mammal Observers (MMO's) and Passive Acoustic Monitoring on board the survey vessel to monitor for marine mammals and fauna visually and ensure that the survey is conducted in compliance with the specified guidelines as stated in the Environmental Management Programme.

Crew changes will occur by the support or survey vessel calling to port. The onshore logistics base will be either in the Port of Cape Town or the Port of Saldanha Bay.

Figure 1 shows the location of the proposed project area.

Figure 1: Locality of proposed TGS Orange Basin Reconnaissance Project.



The purpose of this report is to provide baseline information regarding the socio-economic environment, to identify possible social and economic impacts and to suggest ways in which these impacts can be mitigated. This will assist decision-makers on the project in making informed decisions by providing information on the potential or actual consequences of their proposed activities. The process entailed the following:

- A baseline socio-economic description of the affected environment;
- Identification of potential social and economic change processes that may occur as a result of the project; and
- Identification of potential social and economic impacts.

JC28

One of the ways in which social risk can be managed is by conducting a social impact assessment (SIA). Such an assessment can assist with identifying possible social impacts and risks. Disregarding social impacts can alter the cost-benefit equation of development and in some cases even undermine the overall viability of a project. A proper social impact assessment can have many benefits for a proposed development (UNEP, 2002) such as:

- Reduced impacts on communities of individuals;
- Enhanced benefits to those affected;
- Avoiding delays and obstruction – helps to gain development approval (social license);
- Lowered costs;
- Better community and stakeholder relations; and
- Improved proposals.

More detail on the scope of each of these phases is included in the section below.

2 Scope of Work

The purpose of the SIA is to provide input in the Environmental Impact Assessment (EIA)/ Environmental Management Programme (EMPr) Report for the proposed seismic reconnaissance study.

3 Methodology

Scientific social research methods were used for this assessment. To clarify the process to the reader, this section will start with a brief explanation of the processes that have been used in this study.

3.1 Information base

The information used in this report was based on the following:

- A literature review (see list provided in the References);
- Data from Statistics South Africa;
- The public participation records provided by EIMS;
- Professional judgement based on experience gained with similar projects; and
- Consultation with affected stakeholders in August and September 2022. It must be noted that not every individual in each community could be consulted. Consultations took place in Hout Bay, Steenberg's Cove, Lamberts Bay and Port Nolloth. Due to other commitments the meeting with the Gurlqua leadership could not take place. The meeting in Hondeklip Bay got cancelled at the last minute by the stakeholders.

3.2 Assumptions and limitations

The following assumptions and limitations were relevant:

1. Not every individual in the community could be interviewed therefore only key people in the community were approached for discussion. Additional information was obtained using existing data.
2. The social environment constantly changes and adapts to change, and external factors outside the scope of the project can offset social changes, for example changes in local political leadership, droughts or economic conditions. It is therefore difficult to predict all impacts to a high level of accuracy, although

care has been taken to identify and address the most likely impacts in the most appropriate way for the current local context within the limitations.

3. Given that the survey will be conducted over a short period of time, the the impacts will be short term and from an outsiders perspective may appear as inconsequential. However, the outcomes of the survey will introduce new social impacts, and the potential of these impacts occuring is already causing fear and uncertainty amongst coastal communities. Communities view the survey as the beginning of potentially significant changes in their socio-economic environment.

4. Social impacts can be felt on an actual or perceptual level, and therefore it is not always straightforward to measure the impacts in a quantitative manner.

5. Social impacts commence when the project enters the public domain. Some of these impacts will occur irrespective of whether the project continues or not, and other impacts have already started. These impacts are difficult to mitigate and some would require immediate action to minimise the risk.

6. There are different groups with different interests in the community, and what one group may experience as a positive social impact, another group may experience as a negative impact. This duality will be pointed out in the impact assessment phase of the report.

7. Social impacts are not site-specific, but take place in the communities surrounding the proposed development.

8. Limited time was available for conducting the assessment.

3.3 Social Impact Assessment Model

The theoretical model used for this impact assessment was developed by Slootweg, Vanclay and Van Schooten and presented in the *International Handbook of Social Impact Assessment* (Vanclay & Becker, 2003). This model identifies pathways by which social impacts may result from proposed projects. The model differentiates between social change processes and social impacts, where the social change process is the

SC25

pathway leading to the social impact. Detail of how the model works is not relevant to this study, but it is important to understand the key concepts, which will be explained in the following paragraphs.

Social change processes are set in motion by project activities or policies. A social change process is a discreet, observable, and describable process that changes the characteristics of a society, taking place regardless of the societal context (that is, independent of specific groups, religions etc.) These processes may, in certain circumstances and depending on the context, lead to the experience of social impacts (Vanclay, 2003). If managed properly, however, these changes may not create impacts. Whether impacts are caused will depend on the characteristics and history of the host community, and the extent of mitigation measures that are put in place (Vanclay, 2003). Social change processes can be measured objectively, independent of the local context. Examples of social change processes are an increase in the population, relocation, or the presence of temporary workers.

For the purpose of this report, the following social change process categories were considered:

- Demographic processes;
- Economic processes;
- Geographic processes;
- Institutional and legal processes;
- Emancipatory and empowerment processes;
- Socio-cultural processes; and
- Other relevant processes.

The *International Association for Impact Assessment* (2003) states that Social Impact Assessment includes the processes of analysing, monitoring, and managing the intended and unintended social consequences, both positive and negative, of planned interventions (policies, programs, plans, projects) and any social change processes

EC28

Invoked by these interventions. Its primary purpose is to bring about a more sustainable and equitable biophysical and human environment.

A social impact is something that is experienced or felt by humans. It can be positive or negative. Social impacts can be experienced in a physical or perceptual sense. Therefore, two types of social impacts can be distinguished:

- **Objective social impacts** – i.e. impacts that can be quantified and verified by independent observers in the local context, such as changes in employment patterns, in standard of living or in health and safety.
- **Subjective social impacts** – i.e. impacts that occur "in the heads" or emotions of people, such as negative public attitudes, psychological stress or reduced quality of life.

It is important to include subjective social impacts, as these can have far-reaching consequences in the form of opposition to, and social mobilisation against the project (Du Preez & Perold, 2005).

For the purpose of this SIA, the following Social Impact Assessment categories were investigated:

- Health and social well-being;
- Quality of the living environment;
- Economic impacts and material well-being;
- Cultural impacts;
- Family and community impacts;
- Institutional, legal, political and equity impacts; and
- Gender impacts.

Relevant criteria for selecting significant social impacts included the following:

- Probability of the event occurring;
- Number of people that will be affected;

- Duration of the impact;
- Value of the benefits or costs to the impacted group;
- Extent to which identified social impacts are reversible or can be mitigated;
- Likelihood that an identified impact will lead to secondary or cumulative impacts;
- Relevance for present and future policy decisions;
- Uncertainty over possible effects; and
- Presence or absence of controversy over the issue.

The model was adapted to suit the South African context, and where processes and impacts were not relevant to the study, it was omitted. Each category has a number of sub-categories, which also have been investigated. The Equator Principles, International Finance Corporation Performance Standards and World Bank Environmental, Health and Safety guidelines were consulted in the writing of this report and the mitigation suggested adheres to these requirements.

3.4 Literature study

A literature search was undertaken to obtain secondary data for the baseline description of the socio-economic environment. The information in this report was acquired via statistical data obtained from Statistics South Africa, SIA literature (see References), previous studies conducted in the area, EIMS's public consultation process and information from reputable sources on the World Wide Web.

3.5 Research approach

Traditionally there are two approaches to SIA, a technical approach, and a participatory approach. A technical approach entails that a scientist remains a neutral observer of social phenomena. The role of the scientist is to identify indicators, obtain objective measures relevant to the situation and provide an expert assessment on how the system will change (Becker, Harris, Nielsen & McLaughlin, 2004). A participatory approach uses the knowledge and experiences of individuals most affected by the proposed changes as the basis for projecting impacts. In this case the

role of the scientist is facilitator of knowledge sharing, interpretation, and reporting of impacts (Becker et al, 2004). A combination of these approaches was used for this study.

The findings presented in this report are based on primary and secondary (desk) research. A qualitative approach was followed for the primary research, while qualitative and quantitative data were used for the secondary research.

The layperson sometimes criticises qualitative research as "subjective" or "not really that scientific". For this reason, it is vital to understand the distinction between qualitative and quantitative research and their respective areas of application.

Qualitative research as a research strategy is usually characterised by the inference of general laws from particular instances, forms theory from various conceptual elements, and explains meaning (David & Sutton, 2004). It emphasises words rather than quantification in the collection and analysis of data. Data collection takes place by using methods such as unstructured or semi-structured interviews, focus groups, observations, etc. Data is not recorded in any standardised coding format but is usually reported according to themes. Qualitative data express information about feelings, values, and attitudes. This approach is used where insight and understanding of a situation is required (Malhotra, 1996). Participants are selected based on their exposure to the experience or situation under review. The aim of qualitative research is to understand, not to quantify and as such it is extremely suitable for assessing social impacts. A potential impact must be understood before it can be assessed appropriately.

Quantitative research as a research strategy usually makes inferences of particular instances by reference to general laws and principles and tends to emphasize what is external to or independent of the mind (objective) and incorporates a natural science model of the research process (David & Sutton, 2004). This makes it easier for a person with a natural or physical sciences background to relate to. This approach emphasises quantification in the collection and analysis of data. Data collection take place by using methods such as structured questionnaires and data is recorded in a numeric or some

other standardised coding format. Data is expressed in numerical format and statistical techniques are usually used to assist with data interpretation. This approach is used when information needs to be generalised to a specific population and participants are usually selected using probability sampling techniques (although non-probability methods can be used depending on the characteristics of the target population).

Although in theory the qualitative phase of this project could be followed by a quantitative phase, for a number of reasons it was not done. A quantitative phase would be more resource intensive in terms of labour, time and cost and the incremental precision obtained in terms of generalisability would not warrant the additional investment. Due to the strong emotional component relating to the perceived impacts, respondents may intentionally magnify the intensity of the impacts or indicate all impacts are equally severe in an attempt to bias the results in their favour, which will reduce the utility of quantitative results as part of the primary research process.

3.6 Ethical issues

The most basic principle of research is that participants should not be harmed by participation in the research project. It is important that research not only does no harm, but also potentially contributes to the wellbeing of others. At times this might place a researcher in a difficult position – what is beneficial to one group may not be beneficial to another (Bless, Higson-Smith & Kagee, 2006). Furthermore, an individual has the autonomy to decide whether to participate in research or not. No person should be forced, either overtly or covertly, to participate in research. Other important principles include justice (based on the assumption that all people are equals), fidelity (keeping promises or agreements, specifically between the researcher and the participant) and respect for participants' rights and dignity. In addition to these overarching ethical principles, important ethical principles that should be met are informed consent, confidentiality, anonymity, and discontinuance. This is in line with international as well as national research practice such as the World Association for Market, Social and Opinion Researchers (ESOMAR) and Southern African

3028

Marketing Research Association (SAMRA) codes of conduct. The researcher has an ethical obligation to develop well-designed projects and execute them with care. Researchers are not allowed to change their data or observations and should report on technical shortcomings, failures, limits of the study, negative findings, and methodological constraints. The honest and accurate reporting of data is also an essential component of scientifically accurate and ethically legitimate research and conclusions should be supported by data.

4 Legislative and Policy Framework

Although there are no explicit acts referring directly to SIA, there are many acts and policies that require specific social outcomes that can be related to this project, and these are discussed in the section below.

4.1 The Constitution of the Republic of South Africa 1996

The current Constitution of the Republic of South Africa 1996 can be regarded as one of the most progressive constitutions in the world. Human rights are enshrined in the South African Constitution, which forms the basis of all the country's legislation. Chapter 2 consists of a Bill of Rights, which explicitly spells out the rights of every South African citizen. Human rights and dignity are fundamental to SIA and it recognises fundamental human rights and the prerogative to protect those rights as core values (Vanclay, 2003). The human rights relevant to the environmental management field that are safeguarded by the Constitution of the Republic of South Africa 1996 in the Bill of Rights, include:

- Right to a healthy environment;
- Right of access to land and to security of tenure; and
- Right to adequate housing and protection against evictions and demolitions.

The right to a protected biophysical environment, the promotion of social development and trans-generational equity is explicitly included in the Constitution of the Republic of South Africa 1996, which states:

"Everyone has the right -

1. To an environment that is not harmful to their health and wellbeing, and
2. To have the environment protected, for the benefit of present and future generations, through reasonable legislative and other measures that:
    1. *Prevent pollution*
    2. *Promote conservation, and*

3. *Secure ecologically sustainable development and use of natural resources while promoting justifiable economic and social development."*

When considering an environment that is not harmful to peoples' health and wellbeing, it is important to reflect on the interconnectedness of biophysical, economic, and social aspects. The impact of development on people, and the true cost of development, as well as the consideration of "who pays the price?" versus "who reaps the benefits?" cannot be ignored in a discussion about human rights and the environment.

The right to a generally satisfactory environment is increasingly seen as a human right in Africa (Du Plessis, 2011), and South Africa's environmental legislation supports this.

4.1.1 The National Environmental Management Act 107 of 1998

The National Environmental Management Act (NEMA) 107 of 1998 states that the State must respect, protect, promote and fulfil the social, economic and environmental rights of everyone and strive to meet the needs of previously disadvantaged communities. It states further that sustainable development requires the integration of social, economic and environmental factors in the planning, evaluation and implementation of decisions to ensure that development serves present and future generations.

Chapter 1 of NEMA contains a list of principles and states clearly that environmental management must place people and their needs at the forefront of its concern, and serve their physical, psychological, developmental, cultural and social interests (NEMA, 1998). It states further that negative impacts on the environment and on peoples' environmental rights must be anticipated and prevented, and if they cannot be prevented, they should be minimised and remedied. It elaborates further on the equity of impacts, and the fact that vulnerable communities should be protected from negative environmental impacts. It refers to the principle that everyone should have equal access to environmental resources, benefits and services to meet their basic

5428

human needs (NEMA, 1998). Therefore there is a clear mandate for environmental and restorative justice in the act, something that must be considered in this project.

Another important aspect of NEMA is the principle of public participation. It states that people should be empowered to participate in the environmental governance processes, and that their capacity to do so should be developed if it does not exist. All decisions regarding the environment should take the needs, interest and values of the public into account, including traditional and ordinary knowledge (NEMA, 1998). There are also specific environmental management acts that fall under NEMA, such as the National Environmental Management, Air Quality Act 39 of 2004 (NEM: AQA), and the National Environmental Management, Waste Act 59 of 2008 (NEM: WA). These acts require similar public participation processes to NEMA and the principles of NEMA also apply to them (Department of Environmental Affairs & Development Planning [DEA&DP], Provincial Government of the Western Cape, 2010).

Chapter 6 of NEMA elaborates on the public participation requirements. This is supplemented by the EIA regulations published in GN 982 of 4 December 2014, which contained requirements for public participation (GN 982 in GG 38282 of 4 December 2014). It provides requirements for the public participation, the minimum legal requirements for public participation processes, the generic steps of a public participation process, requirements for planning a public participation process and a description of the roles and responsibilities of the various role players. A compulsory Public Participation Guideline that was published in 2012 (GN 807 of 10 October 2012) in terms of section J of NEMA (NEMA, 1998) complements these requirements. According to the guidelines, public participation can be seen as one of the most important aspects of the environmental authorisation process. Public participation is the only requirement of the environmental impact assessment process for which exemption cannot be given unless no rights are affected by an application. This stems from the requirement in NEMA that people have a right to be informed about potential decisions that may affect them and that they must be given an opportunity to influence those decisions.

8229

The principles of the National Environmental Management Act 107 of 1998 declare further that community wellbeing and empowerment must be promoted through environmental education, the raising of environmental awareness, sharing of environmental knowledge and experience and any other appropriate means. It states that the social, environmental and economic impacts of activities, including disadvantages and benefits, must be considered, assessed and evaluated, and decisions taken must be appropriate given the assessment and evaluation. NEMA 107 of 1998 recognises that the environment is held in public trust for the people, and therefore the beneficial use of environmental resources must serve the peoples' interest and protect the environment as the peoples' common heritage.

NEMA takes a holistic view of the environment, and promotes the consideration of social, economic, and biophysical factors to obtain sustainable development and achieve effective management of the biophysical environment.

4.1.2 The Mineral and Petroleum Resources Development Act 28 of 2002

The Mineral and Petroleum Resources Development Act (MPRDA) 28 of 2002 is the only environmental act that explicitly requires a social development output, in addition to a public participation process, in the form of a Social and Labour Plan (SLP). In the preamble to the Act it recognises the need to promote local and rural development and the social upliftment of communities affected by resource development. In Section 2 it states that some of the objectives of the act are:

- To substantially and meaningfully expand opportunities for historically disadvantaged persons, including women, to enter the mineral and petroleum industries and to benefit from the exploitation of the nations' mineral and petroleum resources;
- To promote economic growth and mineral and petroleum resources development in the Republic;
- To promote employment and advance the social and economic welfare of all South Africans, and

8203

- To ensure that holders of mining and production rights contribute towards the socio-economic development of the areas in which they are operating.

The MPRDA acknowledges that mineral and petroleum resources are the common heritage of all the people of South Africa and that the State is the custodian thereof for the benefit of all. It states that the Minister of Mineral Resources must ensure the sustainable development of South Africa's mineral and petroleum resources within a framework of national environmental policy, norms and standards while promoting economic and social development (MPRDA, 2002).

In Section 37 of the Mineral and Petroleum Resources Development Act 28 of 2002 it endorses the principles set out in Chapter 1 of the National Environmental Management Act 107 of 1998. In Section 39 of the MPRDA the act explicitly requires a social impact assessment as well as an environmental impact assessment when it states that applicants must:

"...investigate, assess and evaluate the impact of his or her proposed prospecting or mining operations on:

(i) The environment;

(ii) The socio-economic conditions of any person who might be directly affected by the prospecting or mining operation..."

Section 3, Chapter 2, Part I, of the regulations (Government Notice 527, 23 April 2004) published under the MPRDA refers to the public participation process, which must be followed according to the Act. It includes advertising and an invitation to comment on the process.

Sections 40 to 46, Chapter 2, Part II, of the regulations published under the MPRDA deal with the Social and Labour Plan (SLP) requirements (Government Notice 527, 23 April 2004). The Department of Mineral Resources provided guidelines for the development of the SLP (Department of Mineral Resources, 2010). The guidelines specify the objectives of the SLP as:

- Promote economic growth and mineral and petroleum resources development in the Republic;
- Promoting employment and advancing the social and economic welfare of all South Africans;
- Ensuring that holders of mining or production rights contribute towards the socio-economic development of the areas in which they are operating as well as the areas from which the majority of the workforce is sourced, and
- To utilise and expand the existing skills base for the empowerment of Historically Disadvantaged South Africans and to serve the community (Department of Mineral Resources, 2010).

The crux of this section is that the SLP requires applicants for mining and production rights to develop and implement comprehensive Human Resources Development Programmes including Employment Equity Plans, Local Economic Development Programmes and processes to save jobs and manage downscaling and/or closure (MPRDA 28 of 2002). According to the regulations, the above programmes are aimed at promoting employment and advancement of the social and economic welfare of all South Africans whilst ensuring economic growth and socio-economic development. The management of downscaling and/or closure is aimed at minimising the impact of commodity cyclical volatility, economic turbulence and physical depletion of the mineral or production resources on individuals, regions, or local economies. All mines in South Africa are required to compile an SLP, and they must report compliance on a yearly basis (MPRDA, 2002). Compiling an SLP must be done in a participatory manner, and local economic development initiatives must be aligned with the municipal integrated development planning processes. An SLP is not a social impact management plan per se, although it does aim to manage some negative social impacts. The guideline is very clear about the fact that measures put in place for the mitigation of impacts cannot be seen as mine community development projects (Department of Mineral Resources, 2010).

4.1.3 The National Heritage Resources Act 25 of 1999

Although the National Heritage Resources Act (NHRA) 25 of 1999 is not an environmental act per se, it is relevant in the field of environmental management. The

FR28

NHRA affirms that every generation has a moral responsibility to act as trustee of the national heritage for later generations and that the State is obliged to manage heritage resources in the interest of all South Africans. The general principles for heritage management in Chapter 5 of the Act state that in order to ensure that heritage resources are effectively managed, the skills and capacities of persons and communities involved in heritage resources management must be developed. The Act further elaborates on the fact that heritage resources form an important part of the history and beliefs of communities and must be managed in a way that acknowledges the right of affected communities to be consulted and to participate in their management.

The general principles (Chapter 5) state that the identification, assessment and management of the heritage resources of South Africa must:

- Take account of all relevant cultural values and indigenous knowledge systems;
- Take account of material or cultural heritage value and involve the least possible alteration or loss of it;
- Promote the use and enjoyment of and access to heritage resources, in a way consistent with their cultural significance and conservation needs;
- Contribute to social and economic development, and
- Safeguard the options of present and future generations.

The National Heritage Resources Act 25 of 1999 therefore protects the cultural rights and heritage of the people of South Africa. It does not require explicit public participation, or give any guidelines on how the public should participate. It does refer, like the National Environmental Management Act 107 of 1998 and the National Water Act 36 of 1998, to social and economic development. Public participation processes may be requested by the South African Heritage Resources Agency if it deems it necessary for a specific project.

4.1.4 Promotion of Administrative Justice Act 3 of 2000

The Bill of Rights in the Constitution of the Republic of South Africa 1996 states that everyone has the right to administrative action that is legally recognised, reasonable, and procedurally just. The Promotion of Administrative Justice Act (PAJA) 3 of 2000

5028

gives effect to this right. The PAJA applies to all decisions of all State organisations exercising public power or performing a public function in terms of any legislation that negatively affects the rights of any person. The Act prescribes what procedures an organ of State must follow when it takes decisions. If an organ of State implements a decision that impacts on an individual or community without giving them an opportunity to comment, the final decision will be illegal and may be set aside. The Promotion of Administrative Justice Act 3 of 2000 also forces State organisations to explain and give reasons for the manner in which they have arrived at their decisions and, if social issues were involved, and how these issues were considered in the decision-making process.

The Promotion of Administrative Justice Act 3 of 2000 therefore protects the rights of communities and individuals to participate in decision-making processes, especially if these processes affect their daily lives.

4.1.5 Traditional and Khoi-San Leadership Act

The Traditional and Khoi-San Leadership Act 3 of 2019 aims:

- to provide for the recognition of traditional and Khoi-San communities, leadership positions and for the withdrawal of such recognition;
- to provide for the functions and roles of traditional and Khoi-San leaders;
- to provide for the recognition, establishment, functions, roles and administration of kingship or queenship councils, principal traditional councils, traditional councils, Khoi-San councils and traditional sub-councils, as well as the support to such councils;
- to provide for the establishment, composition and functioning of the National House of Traditional and Khoi-San Leaders;
- to provide for the establishment of provincial houses of traditional and Khoi-San leaders;
- to provide for the establishment and composition of local houses of traditional and Khoi-San leaders;
- to provide for the establishment and operation of the Commission on Khoi-San Matters;

- to provide for a code of conduct for members of the National House, provincial houses, local houses and all traditional and Khoi-San councils;
- to provide for regulatory powers of the Minister and Premiers;
- to provide for transitional arrangements;
- to amend certain Acts;
- to provide for the repeal of legislation; and
- to provide for matters connected therewith.

4.1.6 Protection, Promotion, Development and Management of Indigenous Knowledge Act 6 of 2019

The Protection, Promotion, Development and Management of Indigenous Knowledge Act 6 of 2019 intends:

- to provide for the protection, promotion, development and management of indigenous knowledge;
- to provide for the establishment and functions of the National Indigenous Knowledge Systems Office;
- to provide for the management of rights of indigenous knowledge communities;
- to provide for the establishment and functions of the Advisory Panel on indigenous knowledge;
- to provide for access and conditions of access to knowledge of indigenous communities;.
- to provide for the recognition of prior learning;
- to provide for the facilitation and coordination of indigenous knowledge-based innovation; and
- to provide for matters incidental thereto.

4.1.7 Marine Living Resources Act 18 of 1998

The Marine Living Resources Act 18 of 1998 intends:

- to provide for the conservation of the marine ecosystem, the long-term sustainable utilisation of marine living resources and the orderly access to exploitation, utilisation and protection of certain marine living resources; and

5428

- for these purposes to provide for the exercise of control over marine living resources in a fair and equitable manner to the benefit of all the citizens of South Africa; and
- to provide for matters connected therewith.

4.2 Additional governance tools

Legislation is not the only tool that authorities can use to achieve sustainable development and social development outcomes. There are several tools, policies and strategic planning instruments that can contribute to this.

4.2.1 Integrated Development Plans

For the purpose of this project, Integrated Development Plan (IDP) documents of the following municipalities need to be considered:

4.2.1.1 Namakwa District Municipality

In its IDP the Namakwa District Municipality states that its strategic objectives are:

- Monitoring and support local municipalities to deliver basic services which include water, sanitation, housing, electricity and waste management
- Support vulnerable groups in the district
- Improve administrative and financial viability and capability
- Promote and facilitate Local Economic Development (include tourism)
- Enhance good governance (include IGR) (IGR - intergovernmental relations)
- Promote and facilitate spatial transformation and sustainable urban development
- To render municipal health services
- To coordinate the disaster management and fire management services in the district
- Caring for the environment.

4.2.1.1.1 Richtersveld Local Municipality

The Richtersveld Local Municipality indicated in its IDP that its strategic goals/objectives are:

- For every household to have access to clean water, electricity, and sanitation

- To treat all their residents with pride and dignity
- To be an effective and efficient local government
- To be an effective instrument of change within its community
- To be a local government that is accountable with community driven development
- To be the gateway for local economic development and tourism in the north-western coast of the Northern Cape.

4.2.1.1.2 Nama Khoi Local Municipality

The key performance areas of the Nama-Khoi Local Municipality are:

- Basic services delivery
- Municipal financial viability and management
- Local economic development
- Municipal transformation and institutional development
- Good governance and community participation.

4.2.1.1.3 Kamiesberg Local Municipality

The Kamiesberg Local Municipality identified its key performance areas in its IDP as:

- Service delivery – to provide and maintain superior decentralised customer services (water, sanitation, roads, storm water, waste management and electricity)
- Local economic development
- Financial viability
- Municipal transformation
- Good governance.

4.2.1.2 West Coast District Municipality

The West Coast District Municipality stated in its IDP that its objectives are to:

- Care for the social well-being, safety and health of all our communities
- Promote regional economic growth and tourism
- Coordinate and promote the development of bulk and essential services and transport infrastructure

- Foster sound relationships with all stakeholders, especially local municipalities
- Maintain financial viability and good governance.

4.2.1.2.1 Matzikama Local Municipality

The Matzikama Local Municipality identified the following strategic objectives in its IDP:

- Provide municipal basic services to meet demands of growing population and development challenges
- Maintain sufficient revenue resources to enable the municipality to meet its constitutional obligations
- Coordinate, facilitate and stimulate sustainable economic development through strategy, policy and programme development
- Reduce poverty levels as measured by SAMPI
- Maintain sufficient organisation resources, enhance the involvement of the public in the development and decision making processes and provide ethical and professional services to support the needs of the communities
- Provide opportunities to officials and councillors for the development of professional and leadership skills and enhance employment equity in the organisation
- Develop and sustain our spatial, natural and built environment.

4.2.1.2.2 Cederberg Local Municipality

The Bergriver Local Municipality identified the following strategic goals:

- Strengthen financial sustainability and further enhancing good governance
- Sustainable service delivery
- Facilitate an enabling environment for economic growth to alleviate poverty
- Promote safe, healthy, educated and integrated communities
- A sustainable, inclusive and integrated living environment

4.2.1.2.3 Bergrivier Local Municipality

The Cederberg Local Municipality identified the following strategic objectives:

- Improve and sustain basic service delivery and infrastructure development
- Financial viability and economically sustainability

- Good governance, community development and public participation
- Facilitate, expand and nurture sustainable economic growth and eradicate poverty
- Enable a resilient, sustainable, quality and inclusive living environment and human settlements i.e. housing development and informal settlement upgrade
- To facilitate social cohesion, safe and healthy communities
- Development and transformation of the institution to provide a people-centred human resources and administrative services to citizens, staff and council

4.2.1.2.4 Saldanha Bay Local Municipality

The Saldanha Bay Local Municipality identified the following strategic actions to create additional growth:

- Retaining large existing exporting businesses
- Promote Aquaculture-, Fishing-, and Food processing sectors
- Tourism growth
- Attract new industrial investors by creating a more enabling environment
- Maximise the competitive advantages for ports
- Support local SME to access more opportunities
- Availability of credible vocational skills development and tertiary education

4.2.1.2.5 Swartland Local Municipality

The strategic goals of the Swartland Local Municipality are:

- Improved quality of life for citizens
- Inclusive economic growth
- Quality and sustainable living environment
- Caring, competent and responsive institutions, organisations, and business
- Sufficient, affordable and well-run services.

4.2.1.3 City of Cape Town Metropolitan Municipality

The City of Cape Town has sixteen objectives linked to its priorities and foundations:

- Economic growth

- Increased jobs and investment in the Cape Town economy

- Basic services
  - Improved access to quality and reliable basic services
  - End load-shedding in Cape Town over time
  - Well-managed and modernised infrastructure to support economic growth
- Safety
  - Effective law enforcement to make communities safer
  - Strengthen partnerships for safer communities
- Housing
  - Increased supply of affordable, well-located homes
  - Safer, better-quality homes in informal settlements and backyards over time
- Public space, environment and amenities
  - Healthy and sustainable environment
  - Clean and healthy waterways and beaches
  - Quality and safe parks and recreational facilities supported by community partnerships
- Transport
  - A sustainable transport system that is integrated, efficient and provides safe and affordable options for all
  - Safe and quality roads for pedestrians, cyclists and vehicles
- A resilient city
- A more spatial integrate and inclusive city
- A capable and collaborative city government.

4.2.2 Provincial Growth and Development Strategies

The Provincial Growth and Development Strategies of the Northern Cape and Western Cape Provinces need to be considered.

4.2.2.1 Northern Cape Strategic Plan 2020-2035

The four drivers of the Northern Cape Provincial Growth and Development Plan:

823

- Economic transformation, growth and development

  To ensure economic growth and development that will lead to job creation and radical economic transformation for the people of the Northern Cape Province, ten economic drivers or development paths have been identified:

  - Agriculture and agro-processing
  - Mining and mineral beneficiation
  - Tourism market development
  - Rural development and land reform
  - Development of energy sector
  - Manufacturing and trade
  - Competitive infrastructure development
  - Employment and skills development
  - Innovation and knowledge economy
  - Marine economy

- Social transformation and human welfare

  To sustainably address the social injustices and inequalities in the province, social transformation must be accelerated and deepened towards human development and welfare. The following six drivers have been identified:

  - Quality basic education
  - Quality health care
  - Social cohesion and community participation
  - Social protection and safety
  - Sustainable human developments
  - Employment and skills development

- Environmental sustainability and resilience

  The Northern Cape Province has an abundance of natural resources and environmental assets. While these present a wide range of economic opportunities, a concerted effort must be made to ensure that these are protected and enhance to support the developmental objectives of the

province. As the province is an arid region, it must be ensured that enough is done to mitigate the real threat of climate change.

- Effective, efficient, and accountable governance

  A capable and accountable government based on strong inter-governmental cooperation and participatory governance with civil society will be better positioned and capable to perform seamless services based on the needs of those on whose behalf they govern. Three drivers have been identified to facilitate effective, efficient, and accountable governance:

  - Developmental and democratic state
  - Effective local government
  - International relations

4.2.2.2 Western Cape Provincial Strategic Plan 2019-2024

Vision has five strategic priorities with the following problem areas and focus areas:

- Safe and cohesive communities – a place where residents and visitors feel safe
  - Problem areas
    - Violence and violent crime
    - Police capacity and public trust
    - Cohesive communities
  - Focus areas
    - Enhanced capacity and effectiveness of policing and law enforcement
    - Strengthened youth-at-risk referral pathways and child- and family centred initiatives to reduce violence
    - Increased social cohesion and safety in public places
- Growth and jobs – an enabling environment for the private sector and markets to drive growth and create jobs
  - Problem areas
    - Weak economic performance persists
    - Unemployment persists
    - Climate change impacts and resource pressures

JC28

- Focus areas
  - Increasing investment
  - Building and maintaining infrastructure
  - Growing the economy through export growth
  - Creating opportunities for job creation through skills development
  - Creating an enabling environment for economic growth through resource resilience

- Empowering people -residents have opportunities to shape their lives and the lives of others, to ensure a meaningful and dignified live
  - Problem areas
    - Children and families live in unhealthy, violent, neglectful and dysfunctional environments that impede proper development
    - Children have unequal access to quality holistic education and extended learning opportunities, which limits post-schooling success
    - Youth engage in unhealthy and risky behaviours, have few educational and economic opportunities, and become disconnected from productive society
    - Health outcomes are uneven between rich and poor and, despite successes in areas like HIV treatment and sexual and reproductive health, there is an inability to fulfil the growing demand for health services
  - Focus areas
    - Children and families
    - Education and learning
    - Youth and skills
    - Health and wellness

- Mobility and spatial transformation – residents live in well-connected, vibrant, and sustainable communities and move around efficiently on safe, affordable, low-carbon public transport
  - Problem areas
    - Poor communities far from social and economic opportunities

- Inadequate public transport
- Infrastructure backlogs and challenges

- Focus areas
  - Create better linkages between places through safe, efficient, and affordable public transport
  - Inclusive places of opportunities
  - More opportunities for people to live in better locations
  - Improving the places where people live

- Innovation and culture – government services are delivered to the people in an accessible, innovative, and citizen-centric way
  - Problem areas
    - Inward-focused organisational culture
    - Western Cape Government innovation exists, but is not fully embedded
    - Limited integration across the spheres of government and with external partners
    - Good governance is primarily driven by compliance processes
    - Talent and staff development is not responsive to the changing world of work
  - Focus areas
    - Citizen-centric culture
    - Innovation for impact
    - Integrated service delivery
    - Governance transformation
    - Talent and staff development

4.2.3 National Development Plan

On 11 November 2011 the National Planning Commission released the National Development Plan: Vision for 2030 (NPC, 2012) for South Africa and it was adopted as government policy in August 2012. The National Development Plan (NDP) was undertaken to envision what South Africa should look like in 2030 and what action

steps should be taken to achieve this (RSA, 2013). The aim of the NDP is to eliminate poverty and reduce inequality by 2030. The report identifies nine central challenges to development in South Africa:

1. Too few people work.
2. The standard of education for most black learners is of poor quality.
3. Infrastructure is poorly located, under-maintained and insufficient to foster higher growth.
4. Spatial patterns exclude the poor from the fruits of development.
5. The economy is overly and unsustainably resource intensive.
6. A widespread disease burden is compounded by a failing public health system.
7. Public services are uneven and often of poor quality.
8. Corruption is widespread.
9. South Africa remains a divided society (NPC, 2012).

The plan focuses on creating an enabling environment for development and wants to shift from a paradigm of entitlement to a paradigm of development that promotes the development of capabilities, the creation of opportunities and the involvement of all citizens (NPC, 2012). The National Development Plan (NPC, 2012) wants to achieve the following:

1. An economy that will create more jobs.
2. Improving infrastructure.
3. Transition to a low-carbon economy.
4. An inclusive and integrated rural economy.
5. Reversing the spatial effects of apartheid.

6. Improving the quality of education, training, and innovation.
7. Quality healthcare for all.
8. Social protection.
9. Building safer communities.
10. Reforming the public service.
11. Fighting corruption.
12. Transforming society and uniting the country.

Each of the points above is a chapter in the plan and contains a range of targets and proposals. Some are general statements of policy intent, while others are specific policy proposals, actions or processes that should take place (NPC, 2012).

4.2.4 Sustainable Development Goals

All 189 Members States of the United Nations, including South Africa, adopted the United Nations Millennium Declaration in September 2000 (UN, 2000). The commitments made by the Millennium Declaration are known as the Millennium Development Goals (MDGs), and 2015 was targeted as the year to achieve these goals. The United Nations Open Working Group of the General Assembly identified seventeen sustainable development goals (Figure 2), built on the foundation of the MDGs as the next global development target (UN, 2014). The sustainable development goals include aspects such as ending poverty, addressing food security, promoting health, wellbeing and education, gender equality, water and sanitation, economic growth and employment creation, sustainable infrastructure, reducing inequality, creating sustainable cities and human settlements, and addressing challenges in the physical environment such as climate change and environmental resources (UN, 2014). These aspects are included in the NPD, and it can therefore be assumed that South Africa's development path is aligned with the international development agenda.

Figure 2: Sustainable Development Goals (Source: www.un.org)

4.3 National and international standards

National and international industry standards aimed at sustainable development and social justice specifically have become abundant in the last decade. Many industries use these standards as indicators for best practice. The discussion below highlights only a few of these standards.

4.3.1 ISO 26000:2010/SANS 26000:2010

Performance standards have long been a voluntary tool used by industry to achieve certain outcomes. The first standard on social responsibility, ISO 26000 was published on 1 November 2010 (ISO, 2010). It was developed using a multi-stakeholder approach involving experts from more than 90 countries and 40 international or broadly based regional organisations involved in different aspects of social responsibility (ISO, 2010).

The South African Bureau of Standards (SABS), a statutory body that is mandated to develop, promote and maintain South African National Standards (SABS, [sa]) adopted the ISO 26000 Standard as a South African National Standard (SANS) 26000:2010.

Social responsibility is defined in the standard as the responsibility of an organisation for the impacts of its decisions and activities on society and the environment, through transparent and ethical behaviour that contributes to sustainable development, including health and welfare of society; takes into account the expectations of the stakeholders; complies with applicable law and is consistent with international behaviour norms, and is integrated throughout the organisation and practiced in its relationships (ISO, 2010).

The document identifies seven principles for social responsibility and seven core subjects that should be addressed by organisations. The seven principles for social responsibility are accountability, transparency, ethical behaviour, respect for stakeholder interests, respect for the rule of law, respect for international norms of behaviour and respect for human rights (ISO, 2010). The core subjects that should be addressed include organisational governance, human rights, labour practices, environment, fair operating practices, consumer issues and community involvement and development (ISO, 2010). Economic aspects, health and safety and the value chain are dealt with throughout the seven core subjects, and gender issues are considered.

ISO 26000 is a good introduction to what social responsibility is and what measures should be taken to move towards being a more socially responsible company. It deals with equity issues and can encourage social development initiatives by companies through activities such as social investment projects, employment creation, skills development and income creation. Any company operating in area where people are affected by their activities has a social responsibility towards the affected community, and as such it would be in the interest of TGS to address the core subjects as suggested by ISO 26000:2010.

4.3.2 International Social Performance Standards/Initiatives

There is a profusion of global initiatives aiming at assisting companies to make their operations more sustainable. Human rights, environmental protection and social justice are gaining support from industry. The social agenda forms an important part of this trend. Only a few relevant initiatives will be mentioned in this section.

The Global Reporting Initiative (GRI) is a leading organisation in the sustainability field that promotes sustainability reporting as a way for companies to become more sustainable and contribute to sustainable development. A company publishes a sustainability report to report the economic, social and environmental impacts of its everyday activities, present its values and governance model and explain the link between its strategy and its commitment to sustainable development (GRI, [sa]). The GRI have strategic partnerships with the United Nations Environment Programme, the United Nations Global Compact, the Organisation for Economic Co-operation and Development and the International Organisation for Standardisation, amongst others (GRI, [sa]). The social category relates to the impact of the company on the social systems in which it operates. The social category consists of four subcategories namely labour practices and decent work; human rights; society; and product responsibility. Each of the categories is unpacked by using a number of aspects that should be considered (GRI, [sa]). GRI Focal Points are national offices that drive the initiatives in particular countries and regions. On 26 February 2013 the GRI Focal Point South Africa was launched. South Africa is one of the countries with the largest number of GRI reporters in the world. The GRI Focal Point South Africa aims to work with multi-national companies to expand and share best practices across the continent (GRI, [sa]).

Many of the multi-lateral funding agencies such as the World Bank have social standards that they must uphold. The most frequently used in the EIA industry is the International Finance Corporation's (IFC) principles (IFC, 2012). The IFC is a member of the World Bank group, and as a part of their sustainability framework they created performance standards on environmental and social sustainability (IFC, 2012). The standards relevant to the social environment are the following:

1. Environmental and Social Standard 1. Assessment and Management of Environmental and Social Risks and Impacts
2. Environmental and Social Standard 2: Labour and Working Conditions
3. Environmental and Social Standard 4: Community Health and Safety

4. Environmental and Social Standard 5 Land Acquisition, Restrictions on Land Use and Involuntary Resettlement

5. Environmental and Social Standard 8: Cultural Heritage

6. Environmental and Social Standard 10. Stakeholder Engagement and Information Disclosure (World Bank, 2016)

Issues such as gender, climate change, water and human rights are addressed across the standards. A guidance note accompanies each standard (IFC, 2012:4). Environmental and social risks and impacts must be managed by using an Environmental and Social Management System. The standard applies to all the activities funded by the IFC for the duration of the loan period. A number of private banks adopted most of the IFC standards in an initiative known as the Equator Principles (Esteves, Franks & Vanclay, 2012).

4.3.3 International Principles for SIA

The practice of SIA is guided by a set of *International Principles* that defines the core values, fundamental principles for development and principles specific to SIA practice (Vanclay, 2003). When the *International Principles* are considered, it is clear that SIA aspires to more than just assessing the impact of development on people and includes sustainable outcomes. The following specific principles refer to these sustainable outcomes (Vanclay, 2003):

1. Development projects should be broadly acceptable to the members of those communities likely to benefit from, or be affected by, the planned intervention.

2. The primary focus of all developments should be positive outcomes, such as capacity building, empowerment, and the realisation of human and social capital.

3. The term "environment" should be defined broadly to include social and human dimensions, and in such inclusion, care must be taken to ensure that adequate attention is given to the realm of the social.

4. Equity considerations should be a fundamental element of impact assessment and of development planning.

5. There should be a focus on socially sustainable development, with the SIA contributing to the determination of best development alternative(s) – SIA (and EIA) has more to offer than just being an arbiter between economic benefit and social cost.

6. In all planned interventions and their assessments, avenues should be developed to build the social and human capital of local communities and to strengthen democratic processes.

7. Local knowledge, experience and acknowledgement of different cultural values should be incorporated in any assessment.

8. Development processes that infringe the human rights of any section of society should not be accepted.

In addition to the *International Principles*, the international SIA community produced a document titled: *Social Impact Assessment: Guidance for assessing and managing the social impacts of projects* (Vanclay, Esteves, Aucamp & Franks, 2015) in April 2015. The purpose of this document is to provide advice to various stakeholders (including proponents) about good practice SIA and social impact management (Vanclay et al., 2015). This document aspires to provide a much-needed benchmark for SIA practice across the globe.

5 Receiving environment

According to the National Environmental Management Act (NEMA, 1998) environment refers to the surroundings in which humans exist. When viewing the environment from a socio-economic perspective the question can be asked what exactly the social environment is. Different definitions for social environment exist, but a clear and comprehensive definition that is widely accepted remains elusive. Barnett & Casper (2001) offers the following definition of human social environment:

> *"Human social environments encompass the immediate physical surroundings, social relationships, and cultural milieus within which defined groups of people function and interact. Components of the social environment include built infrastructure; industrial and occupational structure; labour markets; social and economic processes; wealth; social, human, and health services; power relations; government; race relations; social inequality; cultural practices; the arts; religious institutions and practices; and beliefs about place and community. The social environment subsumes many aspects of the physical environment, given that contemporary landscapes, water resources, and other natural resources have been at least partially configured by human social processes. Embedded within contemporary social environments are historical social and power relations that have become institutionalized over time. Social environments can be experienced at multiple scales, often simultaneously, including households, kin networks, neighbourhoods, towns and cities, and regions. Social environments are dynamic and change over time as the result of both internal and external forces. There are relationships of dependency among the social environments of different local areas, because these areas are connected through larger regional, national, and international social and economic processes and power relations."*

Environment-behaviour relationships are interrelationships (Bell, Fisher, Baum & Greene, 1996). The environment influences and constrains the behaviour of people, but behaviour also leads to changes in the environment. The impacts of a project on

people can only be truly understood if their environmental context is understood. The baseline description of the social environment will include a description of the area within a provincial, district and local context that will focus on the identity and history of the area as well as a description of the population of the area based on a number of demographic, social and economic variables.

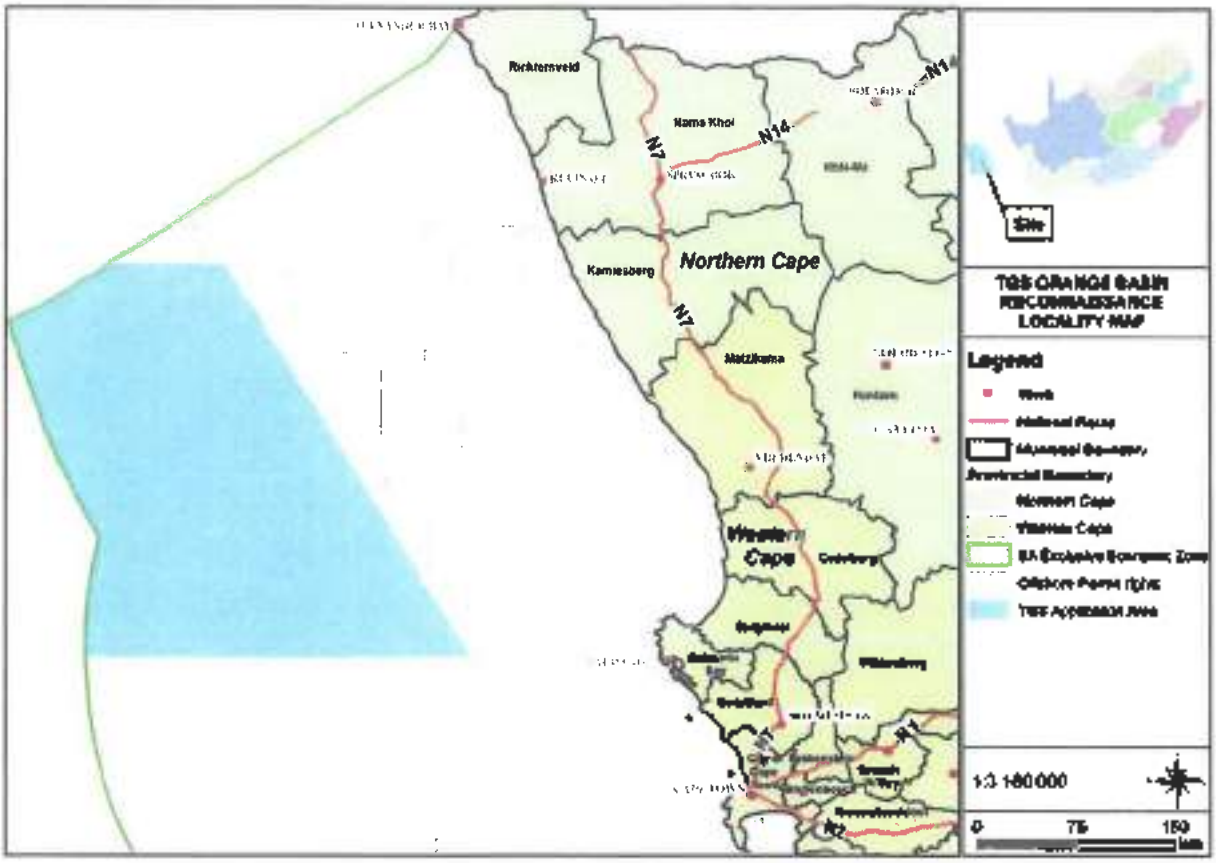
5.1 Description of the area

The proposed project area for the TGS Seismic Reconnaissance project is located on the edge of the South African exclusive economic zone in the Atlantic Ocean. The people potentially affected by the proposed project are those living in the areas adjacent to the ocean whose activities could potentially be affected. The following areas are included in the baseline description of the social environment:

- Northern Cape Province
  - Namakwa District Municipality
    - Richtersveld Local Municipality (Wards 2, 3, 4)
    - Nama Khoi Local Municipality (Ward 8)
    - Kamiesberg Local Municipality (Wards 1, 2)
- Western Cape Province
  - West Coast District Municipality
    - Matzikama Local Municipality (Wards 2, 5, 8)
    - Cederberg Local Municipality (Ward 5)
    - Bergrivier Local Municipality (Wards 6, 7)
    - Saldanha Bay Local Municipality (Wards 1, 3, 5, 6, 11, 12, 14)
    - Swartland Local Municipality (Ward 5)
  - City of Cape Town Metropolitan Municipality (Wards 4, 23, 29, 32, 54, 55, 74, 107, 113, 115)

Figure 3 shows the location of the proposed project area in relation to these municipal areas.

Figure 3: Location of the proposed project area.



5.1.1 Northern Cape Province

The Northern Cape Province is South Africa's largest province. It takes up almost a third of the country and covers an area of 372 889 km² (www.municipalities.co.za). It is bordered by the provinces of North West, Free State, Eastern Cape and Western Cape as well as the countries of Namibia and Botswana and the Atlantic Ocean. It consists of the Frances Baard, John Taolo Gaetsewe, Namakwa, Pixley Ka Seme and ZF Mgcawu District Municipalities.

The capital of the province is Kimberley and other towns in the province include Springbok, Kuruman, De Aar, Sutherland, Alexander Bay, Port Nolloth, Kathu, Okiep, Springbok, Aggeneys, Upington, Kakamas, Keimoes and Warrenton.

The economy of the province relies mainly on mining and agriculture. Commodities being mined include iron ore, copper, asbestos, manganese, fluorspar, semi-precious stones, and marble. Alluvial diamonds are being extracted from the beaches and sea

in the area around Alexander Bay and Port Nolloth. Agricultural products include sheep, wheat, fruit, grapes, wheat, peanuts, maize, and cotton. The province is known for its dried fruit, wine, and karakul pelt.

The spring-flowers in Namakwaland is a popular tourist attraction. The province also houses the southern hemisphere's largest astronomical observatory at Sutherland.

5.1.1.1 *Namakwa District Municipality*

The Namakwa District Municipality is the largest district municipality in the province and covers an area of 126 836 km² (www.municipalities.co.za). It is bordered by the ZF Mgcawu Local Municipality, the Cape Winelands, West Coast, Pixley Ka Seme and Central Karoo District Municipalities, the country of Namibia and the Atlantic Ocean. It is the largest district in the province, making up almost a third of the province.

The district consists of six local municipalities, namely the Hantam, Kamiesberg, Karoo Hoogland, Khai-Ma, Nama Khoi, and Richtersveld Local municipalities. The capital of the province is Springbok and other towns include Aggeneys, Alexander Bay, Brandvlei, Bulletrap, Calvinia, Carolusberg, Concordia, Eksteensfontein, Fraserburg, Garies, Hondeklip Bay, Kamieskroon, Kleinzee, Koingnaas, Komaggas, Kuboes, Leliefontein/Kamiesberg, Loeriesfontein, Middelpos, Nababeep, Nieuwoudtville, O'Kiep, Onderste Doorns, Pella, Pofadder, Port Nolloth, Richtersveld, Sanddrift, Springbok, Steinkopf, Sutherland, and Williston.

The main economic sectors are tourism and agriculture.

5.1.1.1.1 Richtersveld Local Municipality

The Richtersveld municipality is the smallest municipality in the district and covers an area of 9 608 km² (www.municipalities.co.za). The municipality borders the Atlantic Ocean and the main towns are Alexander Bay, Eksteensfontein, Kuboes, Port Nolloth, Richtersveld and Sanddrift. Port Nolloth is the main economic centre of the municipality.The main economic sectors are mining, agriculture, fishing and tourism0 Richtersveld Local Municipality IDP 2022/2027).

The main challenges that municipality faces relate to infrastructure, and socio-economic, spatial and housing issues, as well as issues relative to social facilities and services. The Richtersveld Municipal area is earmarked for a massive harbour development at Boegoebaai (about 60 km north of Port Nolloth and 20 km south of the border between Namibia and South Africa). This project is currently in its initial phase, and it is envisaged that this development will serve as an enabler of further development in the Northern Cape (Namakwa District Municipality IDP 2022-2027).

The Boegoebaai port is closely linked to the Northern Cape Green Hydrogen Strategy which was launched to the global community at the COP26 summit in Glasgow in November 2021 (www.globalafricanetwork.com). Green hydrogen refers to the production of hydrogen using renewable energy sources (www.un.org). Black/brown hydrogen is produced using coal and grey/blue hydrogen is derived from methane. Being an energy carrier, green hydrogen would act like a battery that allows the storage of excess energy created by renewable sources and would reduce the intermittency of renewables that cannot generate power all hours of the day, ensuring a sufficient and continuous supply of power for the grid.

5.1.1.1.2 Nama Khoi Local Municipality

The Nama Khoi Local Municipality covers an area of 17 990 km^2 (www.municipalities.co.za). It is home to Nama, Khoe and San people who have occupied the area for hundreds of years. The municipality borders the Atlantic Ocean, and the main towns are Bulletrap, Carolusberg, Concordia, Kleinzee, Komaggas, Nababeep, O'Kiep, Springbok, Steinkopf. The main economic activities are mining and tourism, but there are also some government departments. This region is known as the land of the Nama people.

5.1.1.1.3 Kamiesberg Local Municipality

The Kamiesberg Local Municipality covers an area of 14 208 km^2 (www.municipalities.co.za). The municipality borders the Atlantic Ocean and the main towns are Garies, Hondeklip Bay, Kamieskroon, Koingnaas, and Lekkefontein/Kamiesberg. Hondeklip Bay has a harbor that serves fishing and diamond boats (Namakwa District Municipality IDP 2022-2027). It is also a mariculture centre

and popular with tourists for scenic drives and 4x4 routes. Garies and Kamieskroon are known for wildflowers in spring, while Koingnaas is a mining town for alluvial diamonds.

5.1.2 Western Cape Province

The Western Cape Province is located on the southern tip of Africa between the Atlantic and Indian Oceans and is bordered by the Northern Cape and Eastern Cape Provinces. It covers an area of 129 462 km² (www.municipalities.co.za). The province is divided into one metropolitan municipality and five district municipalities. The capital of the province is the city of Cape Town and other major cities and towns include George, Knysna, Paarl, Swellendam, Oudtshoorn, Stellenbosch, Worcester, Mossel Bay and Strand.

The province has a well-established industrial and business base. Main economic activities include finance, real estate, ICT, retail, and tourism. Fishing is the most important industry along the west coast and sheep farming in the Karoo. In terms of agriculture main produce include grapes, fruit, vegetables, and wheat. A number of vineyards are located in the Western Cape Province.

5.1.2.1 West Coast District Municipality

The West Coast District Municipality covers an area of 31 118 km² (www.municipalities.co.za) and is bordered by the Namakwa and Cape Winelands District Municipalities, the City of Cape Town, and the Atlantic Ocean. The municipality consists of five local municipalities, namely the Swartland, Bergrivier, Matzikama, Cederberg and Saldanha Bay Local Municipalities.

The capital of the district is Moorreesburg and other main towns include Abbotsdale, Aurora, Bitterfontein, Chatsworth, Citrusdal, Clanwilliam, Darling, Doring Bay, Ebenhaezer, Eendekuil, Elands Bay, Graafwater, Grotto Bay, Hopefield, Jacobs Bay, Kalbaskraal, Klawer, Kliprand, Koekenaa, Koringberg, Lamberts Bay, Langebaan, Leipoldtville, Lutzville, Malmesbury, Molsviei, Moorreesburg, Nuwerus, Paternoster, Piketberg, Porterville, Putsekloof, Redelinghuys, Riebeeck Kasteel, Riebeeck West,

Rietpoort, Riverlands, Saldanha, St Helena Bay, Stofkraal, Strandfontein, Vanrhynsdorp, Velddrif, Vredenburg, Vredendal, Wupperthal, and Yzerfontein.

Despite lively economic activity in the Swartland, Saldanha and Bergrivier areas, large parts of the district remain impoverished. The district has the second lowest GDPR in the Western Cape Province and income inequality has worsened over the years (West Coast District Municipality IDP 2022-2027). The economic activities are mainly driven by activities within the manufacturing; agriculture, forestry and fishing; as well as wholesale and retail trade sector. The recent drought has had a significant impact on the agriculture, forestry and fishery sectors within the district.

5.1.2.1.1 Matzikama Local Municipality

The Matzikama Local Municipality borders the Northern Cape Province and the Atlantic Ocean. It is the largest of the five municipalities in the district, making up almost half of the district. It covers an area of 12 981 km² (www.municipalities.co.za). There are 18 towns and villages in the municipal area with most of the population being concentrated along the Olifants River and its canal system. The main towns and villages include Bitterfontein, Doring Bay, Ebenhaezer, Klawer, Kliprand, Koekenaa, Lutzville, Molsvlei, Nuwerus, Putsekloof, Rietpoort, Stofkraal, Strandfontein, Vanrhynsdorp,aand Vredendal.

The agriculture, forestry and fishery sector was the main driver of the municipality's economy, followed by the wholesale and retail trade, catering and accommodation sector (Matzikama Local Municipality IDP, May 2022). The municipality is under severe strain with regards to coastal resource use (mining pressure, marine living resources), exploitation of estuarine resources and coastal vulnerabilities (illegal off-road vehicles, illegal camping and coastal erosion). Due to the dwindling fishing stocks the capture fisheries industry closed down more than 10 years ago and the likeliness of it being restored to its original form is unlikely. The only remaining activity of this industry is subsistence and small scale fishing.

Operation Phakisa – Oceans Economy forms part of the Matzikama Coastal Management Plan, also in terms of the socio-economic development of the coastal

0208

zones (Matzikama Local Municipality IDP, May 2022). Operation Phakisa – Oceans Economy was launched in July 2014 as a priority programme of the South African Government with the aim to considerably grow the Ocean Economy's contribution to the country's GDP by 2033. It is a results-driven approach that involves clear plans and targets, ongoing monitoring of progress and making these results public. It focuses on bringing key stakeholders from the public and private sectors, academia as well as civil society organisations together to collaborate in (www.dffe.gov.za):

- Detailed problem analysis;
- Priority setting;
- Intervention planning; and
- Delivery.

The project focuses on six growth areas, namely:

- Marine transport and manufacturing;
- Offshore oil and gas exploration;
- Aquaculture;
- Marine protection services and ocean governance;
- Small harbours; and
- Marine tourism.

The six growth areas are supported by two enablers, namely:

- Skills and capacity building; and
- Research, technology and innovation.

5.1.2.1.2 Cederberg Local Municipality

The Cederberg Local Municipality covers an area of 8 007 km² (www.municipalities.co.za). It is bordered by the Atlantic Ocean and the Cederberg Mountains and is located on the Cape-Namibia corridor. The main towns in the area include Citrusdal, Clanwilliam, Elands Bay, Graafwater, Lamberts Bay, Leipoldtville, and Wupperthal.

The economic activities in the Cederberg Local Municipality are dominated by agriculture and fishing, manufacturing, wholesale and retail trade, catering and accommodation, and transport, storage and accommodation (Cederberg Local Municipality IDP 2022-23). The area consists of a mix of sparsely and densely populated towns with Clanwilliam and Citrusdal serving as the main agricultural

centres. The area is characterised by high levels of unemployment, poverty and social grant dependence. The road network is diverse with national, trunk, main and divisional roads of varying quality.

5.1.2.1.3 Bergrivier Local Municipality

The Bergrivier Local Municipality covers an area of 4 407 km² (www.municipalities.co.za). The main towns in the area include Aurora, Eendekuil, Piketberg, Porterville, Redelinghuys, and Velddrif. The agriculture sector is the largest employer in the municipal area with a contribution of 50.4% to total employment (Bergrivier Local Municipality IDP, May 2022). The four pillars for economic development in the municipal area are agriculture and agro processing; tourism; manufacturing; and the development of small and medium enterprises.

5.1.2.1.4 Saldanha Bay Local Municipality

The Saldanha Bay Local Municipality is the smallest of the five municipalities in the district and covers an area of 2 015 km² (www.municipalities.co.za). The main towns in the area are Hopefield, Jacobs Bay, Langebaan, Paternoster, Saldanha, St Helena Bay, Vredenburg.

The Saldanha Bay area plays an important role in the broader strategic framework of the South African Government as driven by the National Development Plan and National Growth Plan. It was identified as a special intervention area, attributed to the natural deep-water harbour and industrial development prospects that warrants its designation as a national growth management zone. The Saldanha Bay Industrial Development Zone (IDZ) was launched in October 2013 with the aim of serving as an important mechanism to achieve the government's aim of sustainable economic development and job creation in the localised economy. Diversification, and transformation of the historically under-developed and under-supported industrial maritime and energy sectors and broadening of the regional and national economic base through industrialisation (Saldanha Bat Local Municipality IDP, May 2022).

St Helena Bay is one of the world's principal fishing centres. Huge shoals of anchovies and pilchards fed in the area before they were depleted by overfishing. Twelve fish-

processing factories were established along the 21 km curve of the shore from West Point to Sandy Point and Stompneus. The bay is also well known for its snoek, especially during the winter months.

Saldanha Bay is the largest natural bay in South Africa and has a huge iron ore quay and is home to a large variety of fishing vessels. The town is not only important for export, but also hosts a number of other industries, such as crayfish, fish, mussels, oysters, seaweed and many more. It is also home to the South African Military Academy as well as SAS SALDANHA, a naval training unit.

The largest economic sectors in the municipal area are manufacturing, trade, and finance, while the agricultural sector is the largest contributor to employment. The fishing industry and fish processing are the largest primary and secondary industries in the municipality.

5.1.2.1.5 Swartland Local Municipality

The Swartland Local Municipality covers an area of 3 708 km^2 (www.municipalities.co.za). Main towns in the area include Abbotsdale, Chatsworth, Darling, Grotto Bay, Kalbaskraal, Koringberg, Malmesbury, Moorreesburg, Riebeeck Kasteel, Riebeeck West, Riverlands, and Yzerfontein.

The town of Malmesbury fulfils an important niche in the region due to its high development potential that can be attributed to factors like its relative accessibility along the N7 road/rail corridor; proximity to Cape Town; a diversified economic base that not only accommodates agriculture, but also well-developed industrial and commercial sectors; and supportive infrastructure. A number of people moved here and commute to jobs in Cape Town because of the high property rates in the Cape Town Metropolitan area and the tranquil environment that it offers.

Commercial services; Manufacturing; and Agriculture are the biggest contributors to the economy of the municipal area, with Agriculture being the second highest contributor to employment.

5.1.2.2 City of Cape Town Metropolitan Municipality

The City of Cape Town Metropolitan Municipality is situated in the southern peninsula of the Western Cape Province and covers an area of 2 461 km² (www.municipality.co.za). It is South Africa's second largest economic centre and the second most populous city after Johannesburg. It is the provincial capital as well as the legislative capital of South Africa. The city is known for its harbour, floral kingdom and well-known landmarks like Table Mountain and Cape Point.

Main towns and cities in the area include Athlone, Atlantis, Belhar, Bellville, Blackheath, Blouberg, Blue Downs, Brackenfell, Cape Point, Cape Town, Delft, Durbanville, Elsies River, Fish Hoek, Goodwood, Gordon's Bay, Grassy Park, Guguletu, Hout Bay, Khayelitsha, Kommetjie, Kraaifontein, Kuils River, Langa, Macassar, Matroosfontein, Melkbosstrand, Milnerton, Mitchells Plain, Muizenberg, Noordhoek, Nyanga, Parow, Philadelphia, Philippi, Robben Island, Scarborough, Simon's Town, Sir Lowry's Pass, Somerset West, Southern Suburbs, Strand, and Table View.

5.2 Description of the population

The baseline description of the population will take place on three levels, namely provincial, district and local. Impacts can only truly be comprehended by understanding the differences and similarities between the different levels. The baseline description will focus on the municipal areas along the west coast that are most likely to be affected by the proposed project. Where possible, the data will be reviewed on a ward level. The data used for the socio-economic description was sourced from Census 2011. Census 2011 was a *de facto* census (a census in which people are enumerated according to where they stay on census night) where the reference night was 9-10 October 2011. The results should be viewed as indicative of the population characteristics in the area and should not be interpreted as absolute.

The following points regarding Census 2011 must be kept in mind (www.statssa.co.za):

- Comparisons of the results of labour market indicators in the post-apartheid population censuses over time have been a cause for concern. Improvements to key questions over the years mean that the labour market outcomes based

5228

on the post-apartheid censuses must be analysed with caution. The differences in the results over the years may be partly attributable to improvements in the questionnaire since 1996 rather than to actual developments in the labour market. The numbers published for the 1996, 2001, and 2011 censuses are therefore not comparable over time and are different from those published by Statistics South Africa in the surveys designed specifically for capturing official labour market results.

- For purposes of comparison over the period 1996–2011, certain categories of answers to questions in the censuses of 1996, 2001 and 2011, have either been merged or separated.

- The tenure status question for 1996 has been dropped since the question asked was totally unrelated to that asked thereafter. Comparisons for 2001 and 2011 do however remain.

- All household variables are controlled for housing units only and hence exclude all collective living arrangements as well as transient populations.

- When making comparisons of any indicator it must be considered that the time period between the first two censuses is five years and that between the second and third census is ten years. Although Census captures information at one given point in time, the period available for an indicator to change is different.

5.2.1 Population and household sizes

According to the Community Survey 2016, the population of South Africa is approximately 55,7 million and has shown an increase of about 7.5% since 2011. The household density for the country is estimated on approximately 3.29 people per household, indicating an average household size of 3-4 people (leaning towards 3) for most households, which is down from the 2011 average household size of 3.58 people per household. Smaller household sizes are in general associated with higher levels of urbanisation.

The greatest increase in population since 2011 has been in the Swartland and Saldanha Bay Local Municipalities (Table 1) and the increases were well above the national average. The Richtersveld Local Municipality where Port Nolloth is located is the only one of the coastal municipalities in the Northern Cape that showed an increase in population. The Kamiesberg Local Municipality where Hondeklip Bay is located, saw the greatest decrease in population between 2011 and 2016. Population density refers to the number of people per square kilometre and the population density on a national level has increased from 42.45 people per km2 in 2011 to 45.63 people per km2 in 2016. The City of Cape Town had the highest population density in 2016, and the Kamiesberg Local Municipality the lowest. Figure 4 gives a comparison of the population density. The municipalities in the rural areas in the Northern Cape are the least densely populated, while the metropolitan areas in Cape Town have the highest population density. Figure 5 shows the number of people per ward. The wards in the rural areas tend to have less people spread over a greater area, while in the urban areas there are more people in a much smaller area.

Table 1: Population density and growth estimates (sources: Census 2011, Community Survey 2016)

Area	Size in km²	Population 2011	Population 2016	Population density 2011	Population density 2016	Growth in population (%)

Figure 4: Population density (source: Community Survey 2016)

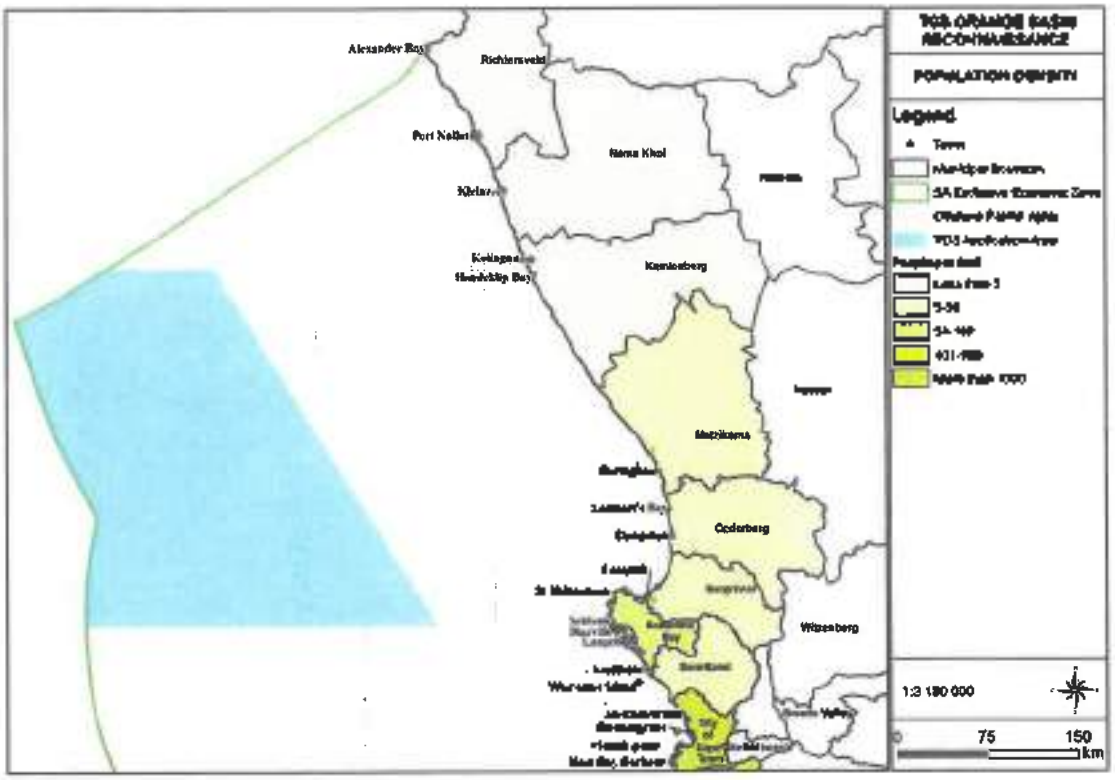

Figure 5: People per ward (source: Census 2011)

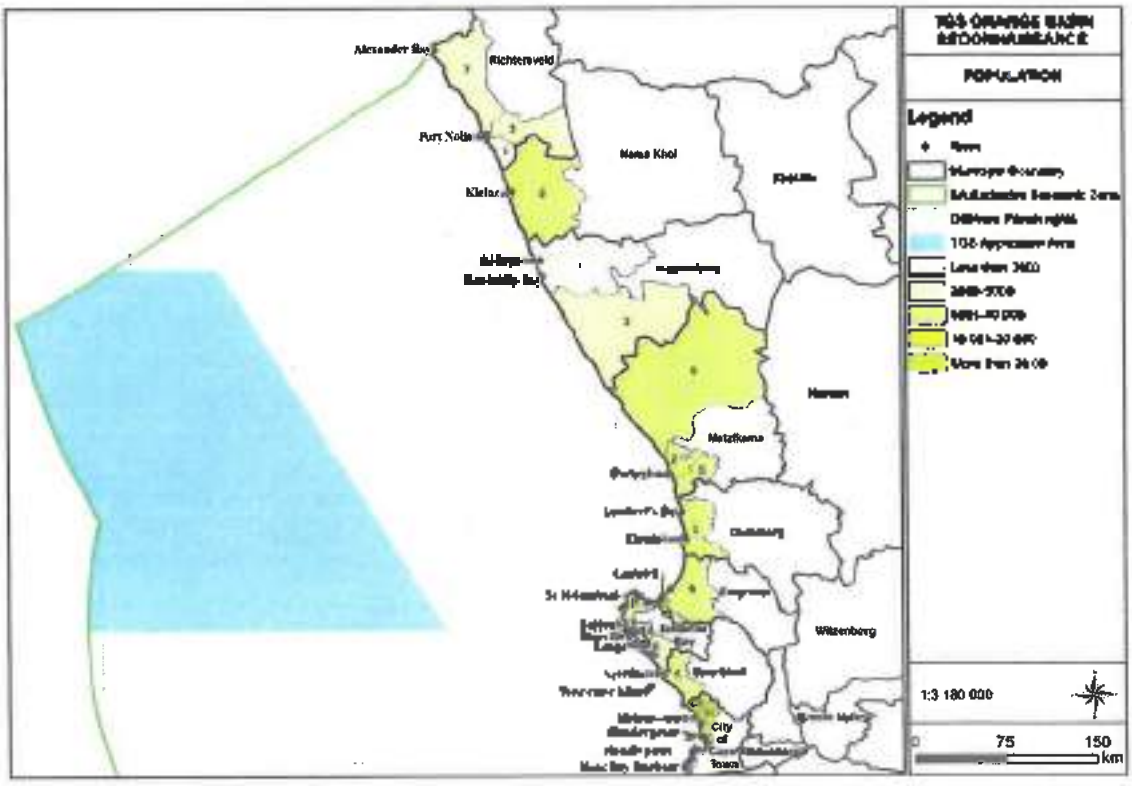

The number of households in the study area has increased on all levels (Table 2). The proportionate increase in households were greater than the increase in population on all levels. The greatest proportional increases in households were in the Swartland and Saldanha Bay Local Municipalities. The average household size has shown a decrease on all levels, which means there are more households, but with less members.

Table 2: Household sizes and growth estimates (sources: Census 2011, Community Survey 2016)

Area	Households 2011	Households 2016	Average household size 2011	Average household size 2016	Growth in households (%)

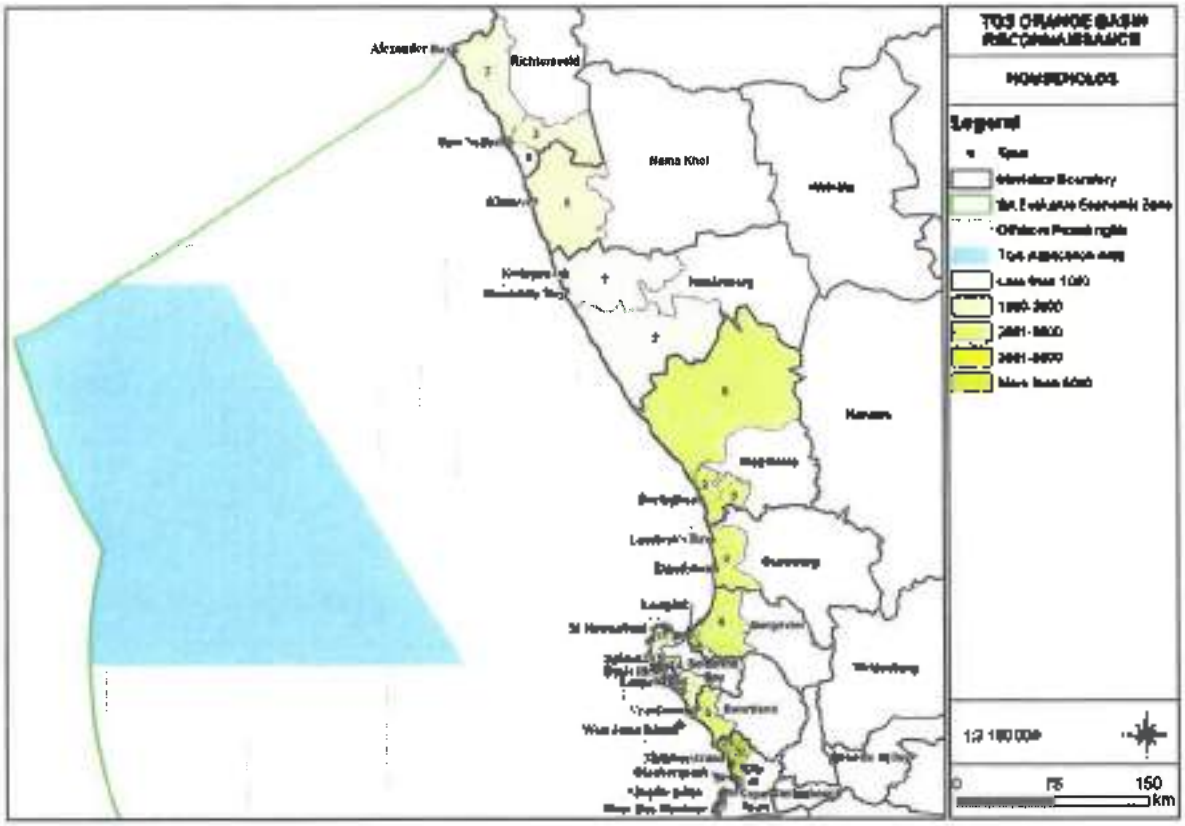
Figure 6 shows the number of households per ward. The wards in the Kamiesberg Local Municipality have the fewest people per ward.

Figure 6: Households per ward (source: Census 2011)



The total dependency ratio is used to measure the pressure on the productive population and refer to the proportion of dependents per 100 working-age population. As the ratio increases, there may be an increased burden on the productive part of the population to maintain the upbringing and pensions of the economically dependent. A high dependency ratio can cause serious problems for a country as the largest proportion of a government's expenditure is on health, social grants and education that are most used by the old and young population.

The Kamiesberg Local Municipality has the highest total dependency ratio (Table 3), while in the Richtersveld Local Municipality have the lowest. Employed dependency ratio refers to the proportion of people dependent on the people who are employed, and not only those of working age. The employed dependency ratio for the Kamiesberg and Nama Khoi Local Municipalities are the highest. This suggests high levels of poverty in these areas. Figure 7 and Figure 8 show the total and employed dependency ratios on a ward level.

1428

Table 3: Total dependency ratios (source: Census 2011).

Area	Total dependency	Youth dependency	Aged dependency	Employed dependency

Figure 7: Total dependency ratios (source: Census 2011)

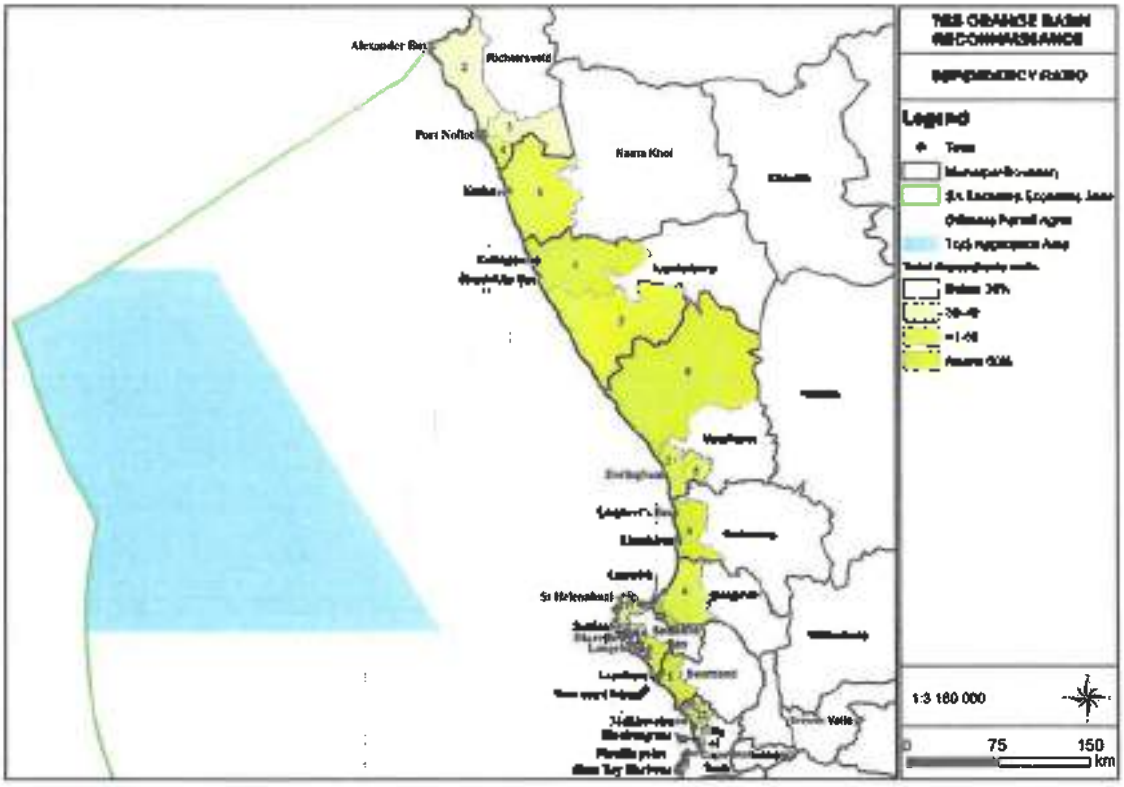

Figure 8: Employed dependency ratio (source: Census 2011).

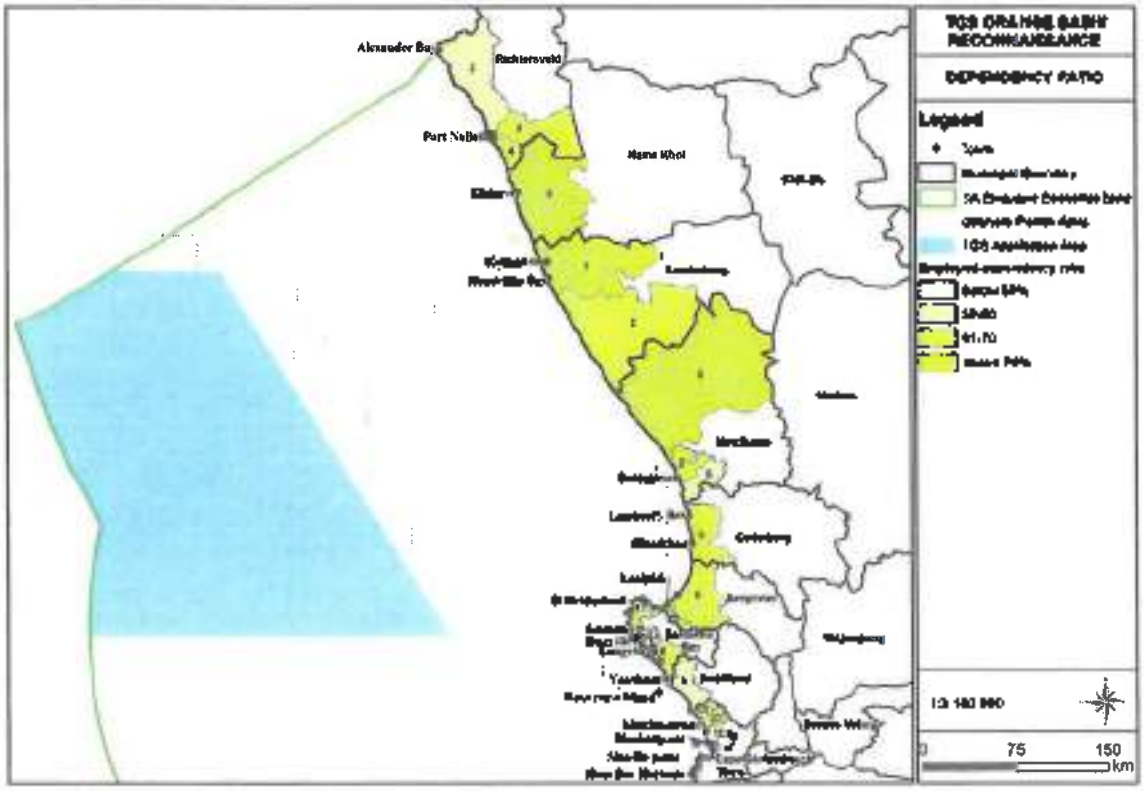

Poverty is a complex issue that manifests itself in economic, social, and political ways and to define poverty by a unidimensional measure such as income or expenditure would be an oversimplification of the matter. Poor people themselves describe their experience of poverty as multidimensional. The South African Multidimensional Poverty Index (SAMPI) (Statistics South Africa, 2014) assess poverty on the dimensions of health, education, standard of living and economic activity using the indicators child mortality, years of schooling, school attendance, fuel for heating, lighting, and cooking, water access, sanitation, dwelling type, asset ownership and unemployment.

The poverty headcount refers to the proportion of households that can be defined as multi-dimensionally poor by using the SAMPI's poverty cut-offs (Statistics South Africa, 2014). The poverty headcount has increased on all levels since 2011 (Table 4), indicating an increase in the number of multi-dimensionally poor households.

The intensity of poverty experienced refers to the average proportion of indicators in which poor households are deprived (Statistics South Africa, 2014). The intensity of poverty has increased slightly on all levels. The intensity of poverty and the poverty headcount is used to calculate the SAMPI score. A higher score indicates a very poor community that is deprived on many indicators. The SAMPI score has decreased in the Northern Cape (Table 4) as well as the Northern Cape municipalities included in the study. In the Nama Khoi Local Municipality, the score remained the same although there was a slight increase in the intensity of the poverty. In the Western Cape the SAMPI score decreased on a provincial level, but in the West Coast District Municipality it has increased.

Table 4: Poverty and SAMPI scores (sources: Census 2011 and Community Survey 2016).

Area	Poverty headcount 2011 (%)	Poverty intensity 2011 (%)	SAMPI 2011	Poverty headcount 2016 (%)	Poverty intensity 2016 (%)	SAMPI 2016

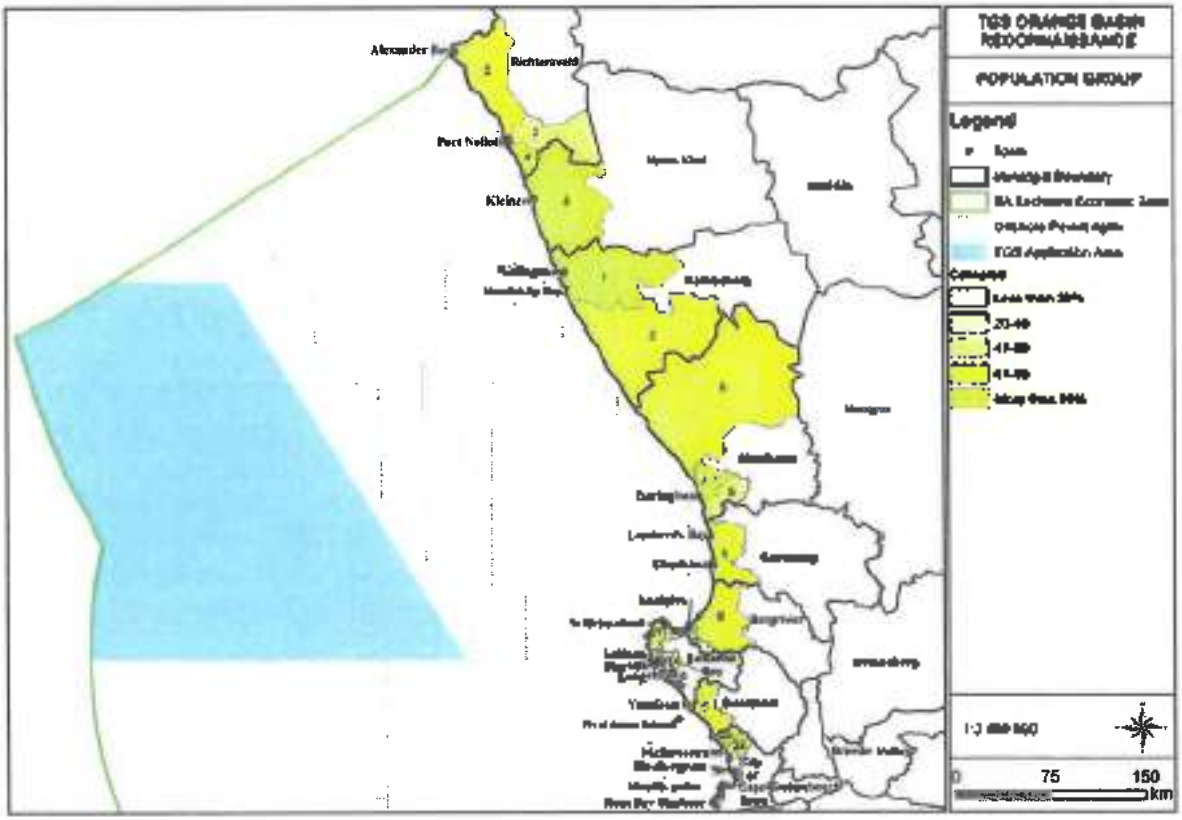
5.2.2 Population composition, age, gender and home language

The majority of the people living in wards adjacent to the ocean are classified as belonging to the Coloured population group (Figure 9). The Coloured population group include Khoe and San people who in general find this classification offensive and they do not identify as such.

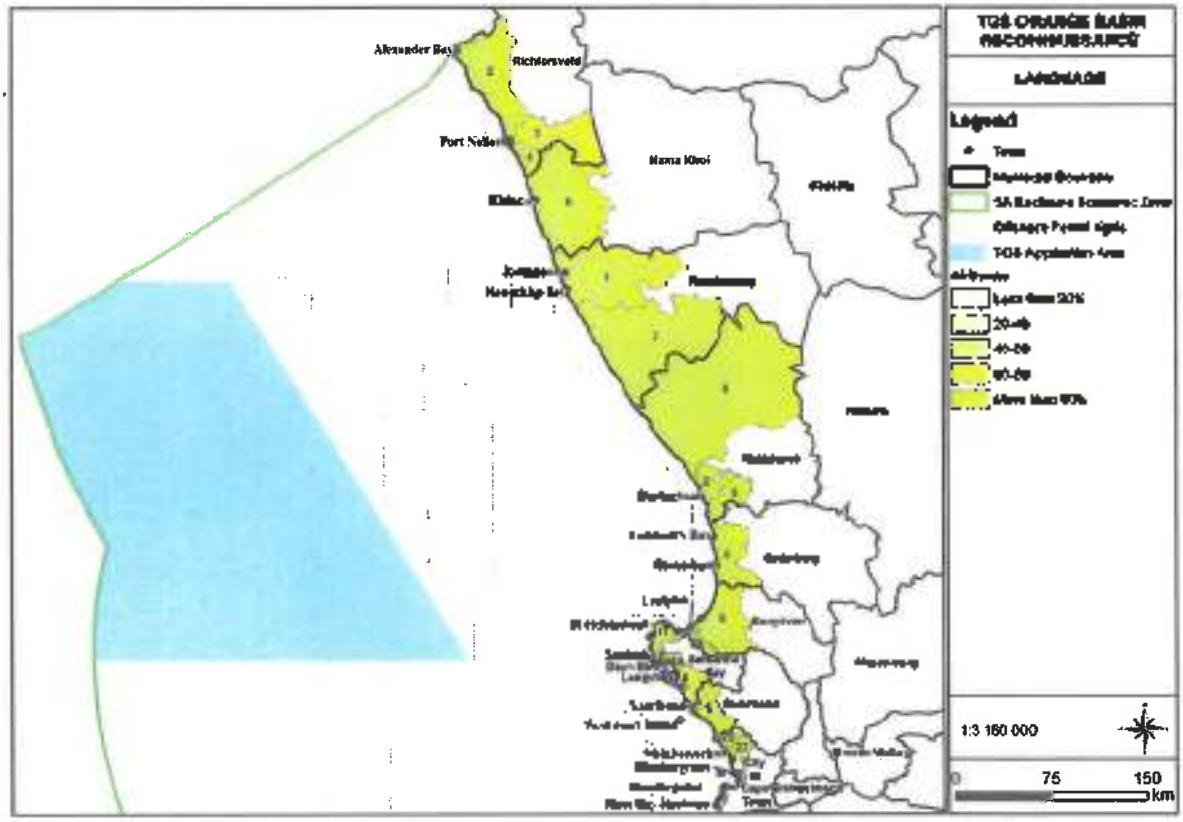
Figure 9: Classified as Coloured (shown in percentage, source: Census 2011)



The Kamiesberg Local Municipality has the highest average age (33.17 years) while the Saldanha Bay Local Municipality has the lowest (29.86 years). Average age varies on a ward level.

The gender distribution is more or less equal in most municipal areas, except for the Richtersveld Local Municipality where there is a bias towards males. This is most likely due to mining activities that are taking place in the area. On a ward level, most people have Afrikaans as home language (Figure 10).

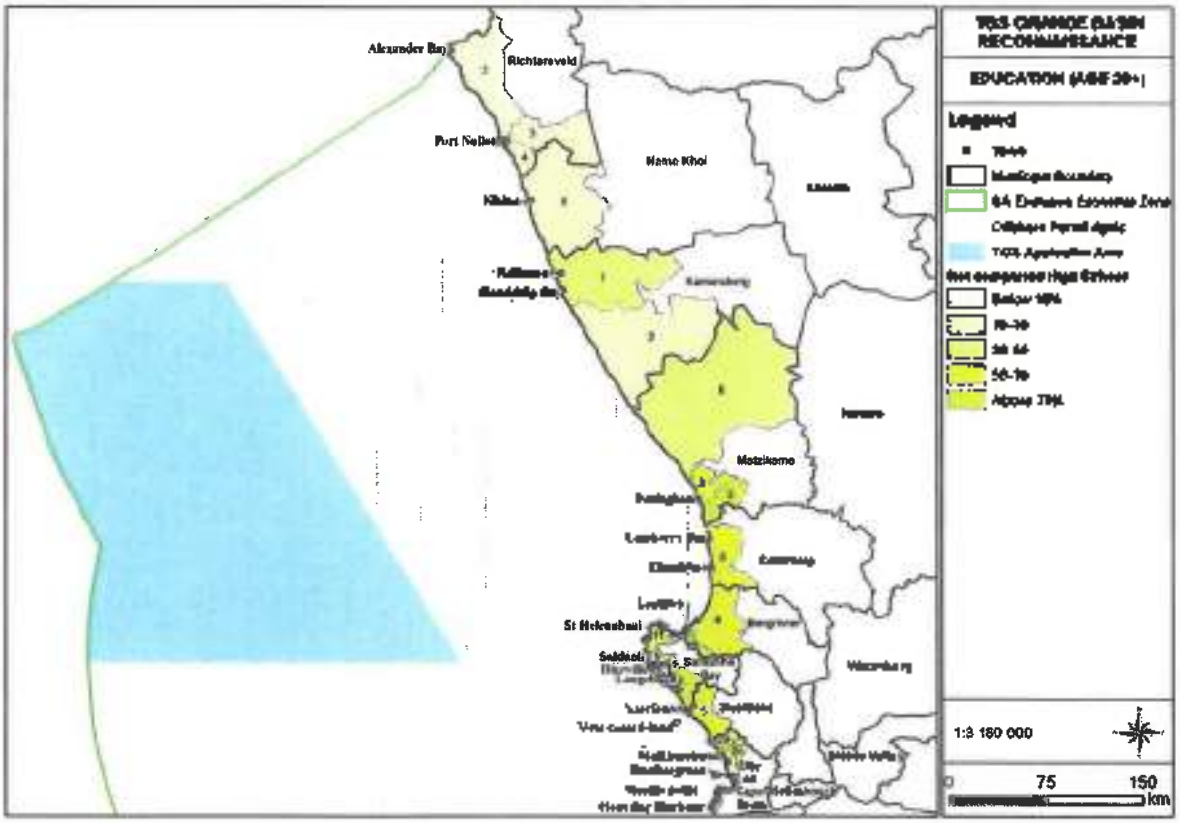
Figure 10: Home language Afrikaans (shown in percentage, source: Census 2011)



5.2.3 Education

The highest proportion of people who did not complete high school is in the Saldanha Bay (73.59%) and the Swartland (72.83%) Local Municipalities while the Matzikama (32.7%) and Nama Khoi (37.37%) Local Municipalities have the lowest proportion of people that did not complete high school (Figure 11).

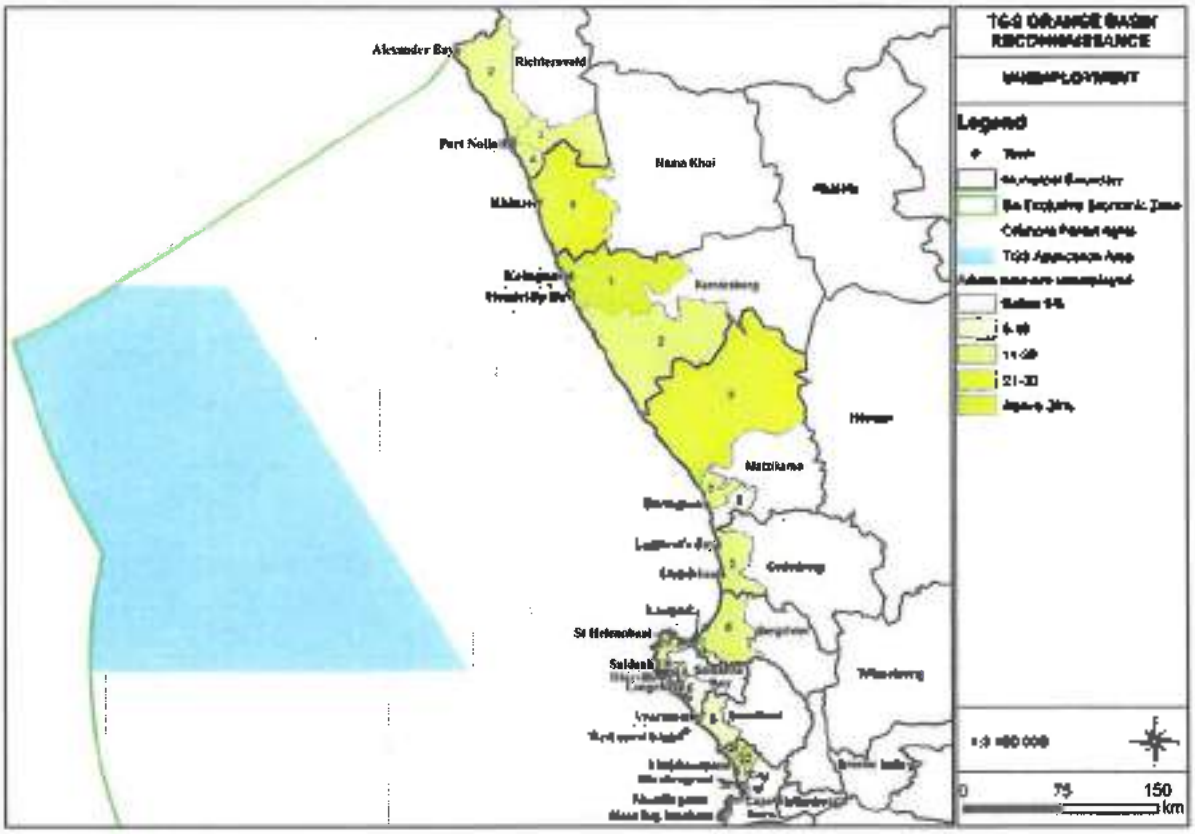
Figure 11: Proportion of people that did not complete secondary school (shown in percentage, source: Census 2011).



5.2.4 Employment

In 2011 the area with the highest proportion of unemployed people was ward 1 in the Kannieberg Local Municipality where Hondeklip Bay is located (Figure 12). The proportion of unemployed people include those actively seeking for work as well as discouraged work seekers. The majority of people who are working, is employed in the formal sector.

Figure 12: Proportion of adults that are unemployed (shown in percentage, source: Census 2011).

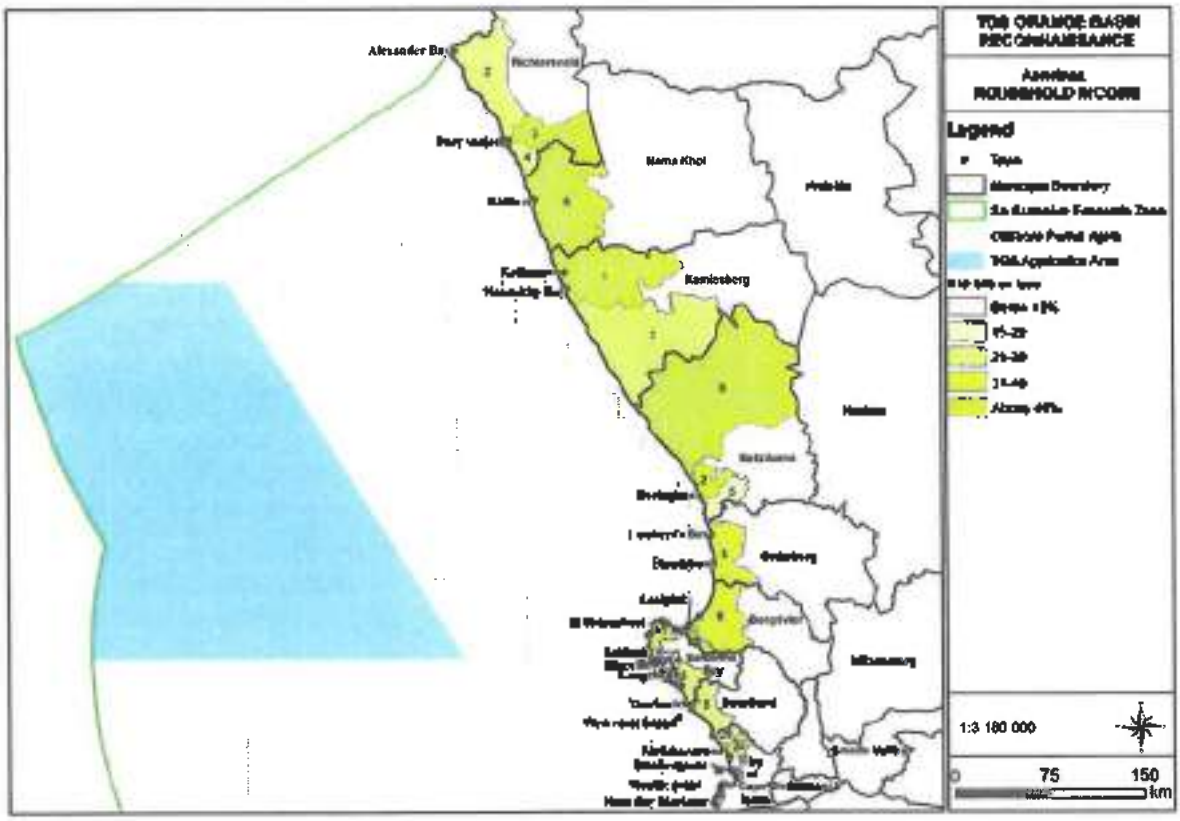


5.2.5 Household income

In 2011 almost a third of households on municipal level had an annual household income of R19 600 or less, with great variation between wards (Figure 13). Statistics South Africa (2015) has calculated the Food Poverty Line (FPL) for the Northern Cape Province as R310 per capita per month for 2011 where the FPL is the Rand value below which individuals are unable to purchase or consume enough food to supply them with the minimum per-capita-per-day energy requirement for good health. The FPL is one of three poverty lines, the others being the upper bound poverty line (UBPL) and the lower bound poverty line (LBPL). The LBPL and UBPL both include a non-food component. Individuals at the LBPL do not have enough resources to consumer or purchase both adequate food and non-food items and are forced to sacrifice food to obtain essential non-food items, while individuals at the UBPL can purchase both adequate food and non-food items. The LBPL for the Northern Cape Province was R457 per capita per month in 2011 and the UBPL R705 per capita per month

respectively. The FPL for Western Cape was R352 per capita per month, the LBPL was R545 and the UPL was R804. Based on this, a household with four members needed an annual household income of approximately R17 000 in 2011 to be just above the FPL. When comparing this with the SAMPI data it seems as if there are more households below the poverty lines in the area than who are multi-dimensionally poor. This is due to the poverty lines using a financial measure and do not take into consideration payment in kind and livelihood strategies such as subsistence farming. If these were to be converted into a Rand value, the poverty line picture may have a closer resemblance to the SAMPI data.

Figure 13: Proportion of households with an annual income of R19 600 or less in 2011 (shown in percentage, source: Census 2011).



5.2.6 Housing

The majority of households live in areas that are classified as urban, except in the Matzikama Local Municipality (Figure 14). The majority of people live in formal dwellings that that are houses or structures that are on a separate stand or yard. The incidence of informal dwellings is relatively low (Figure 15), except for Ward 1 of the

Saldanha Bay Local Municipality where the majority of people live in informal dwellings. Wards 32 and 74 also have a relatively large proportion of households living in informal dwellings.

Figure 14: Proportion of households that live in urban areas (shown in percentage, source: Census 2011).

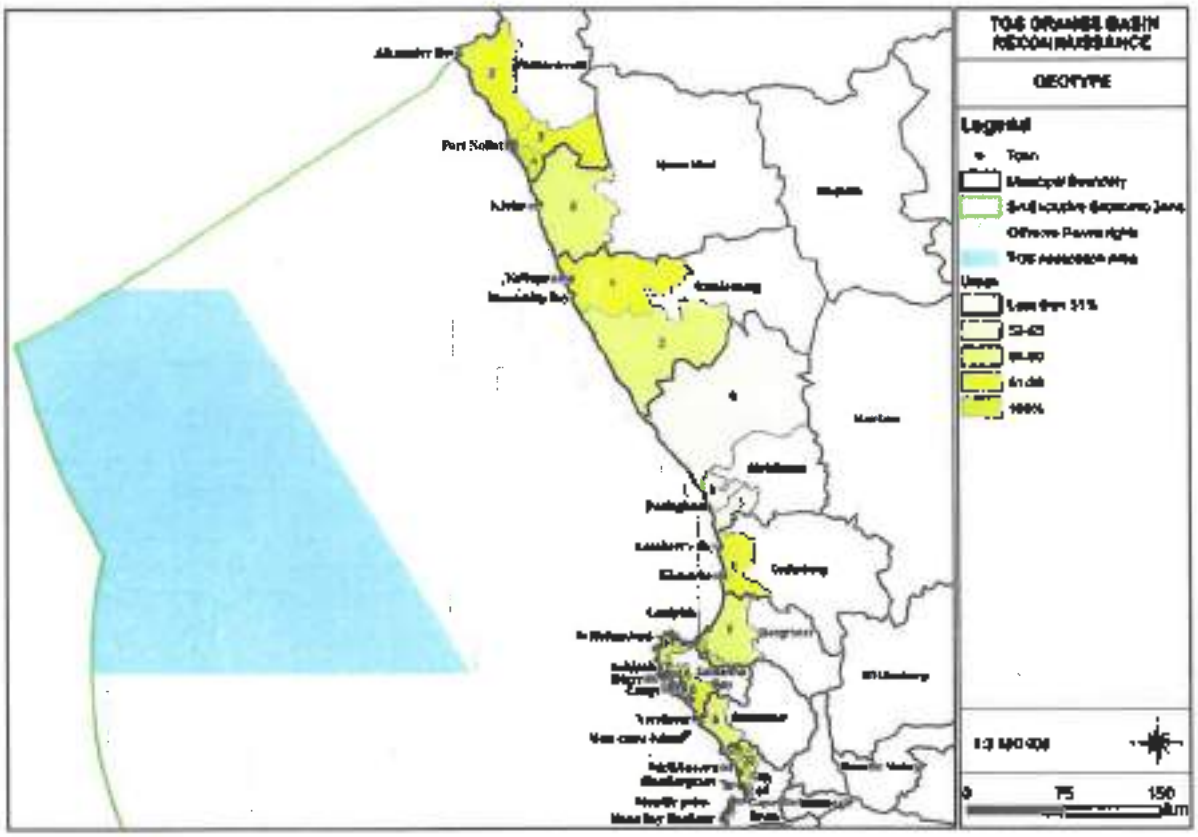


Figure 15: Proportion of households that live in informal dwellings (shown in percentage, source: Census 2011).

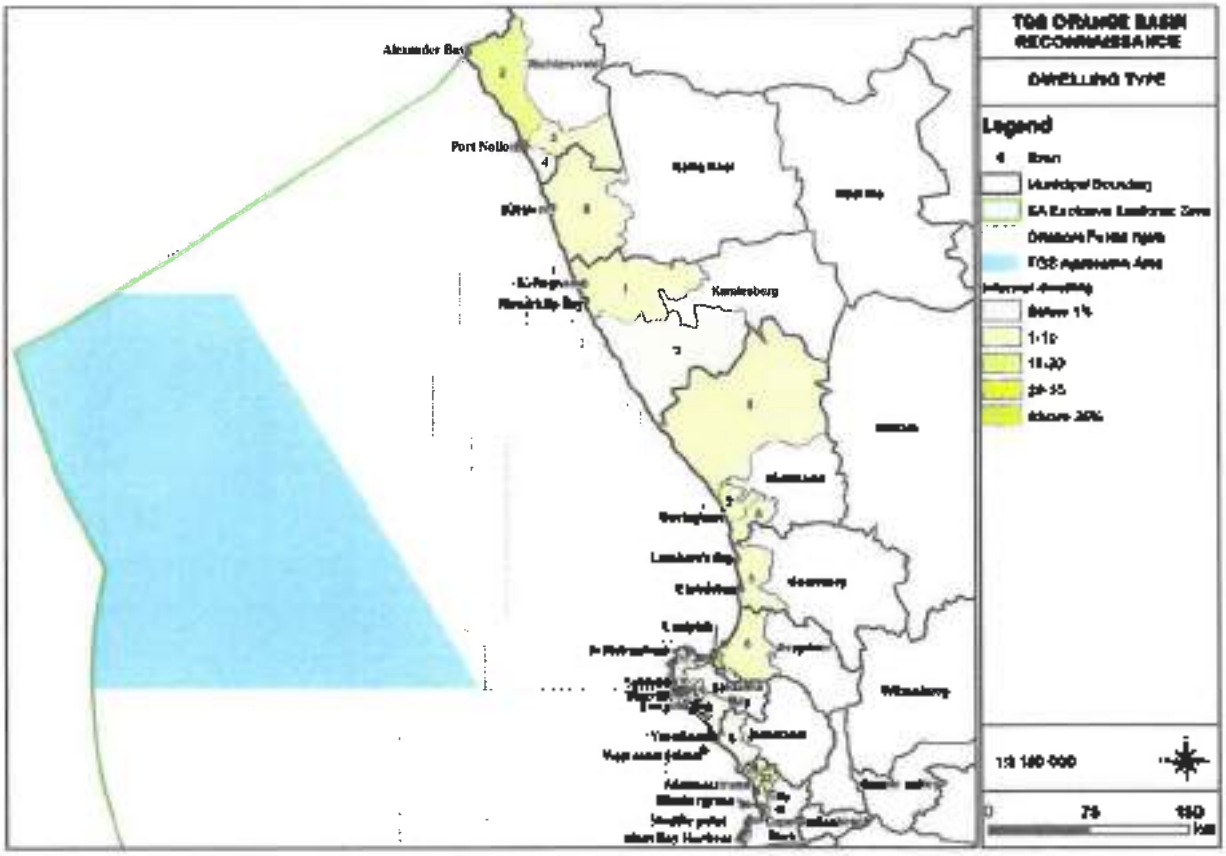
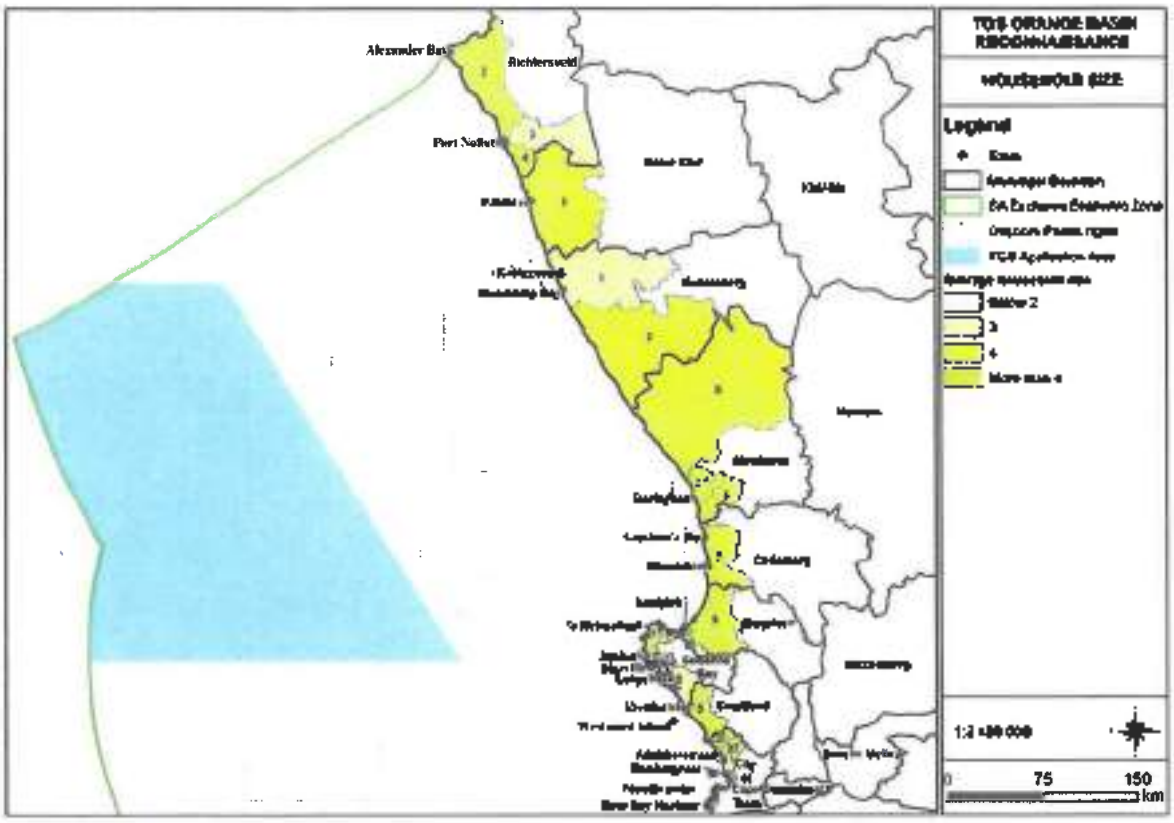


5.2.7 Household size

The average household size in the wards vary between 1.96 people per household and 4.86 people per household (Figure 16).

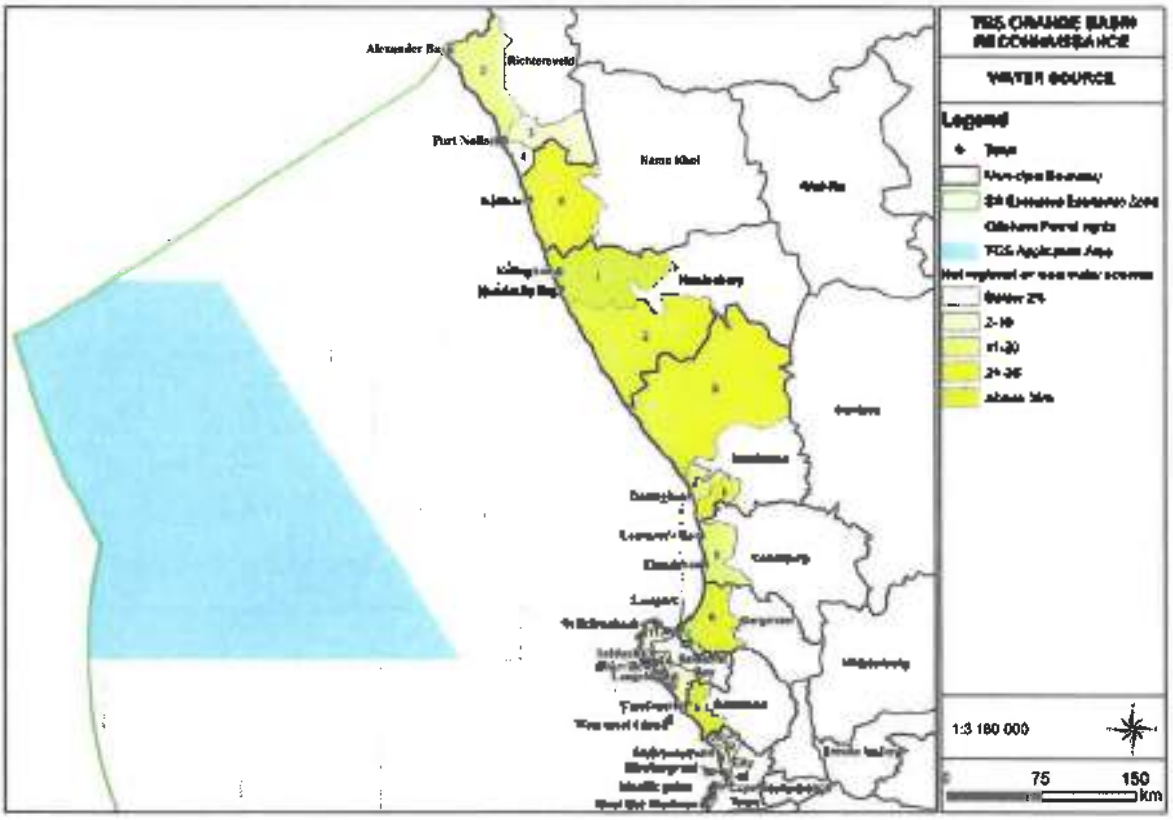
Figure 16: Average household sizes (source: Census 2011).



5.2.8 Access to water and sanitation

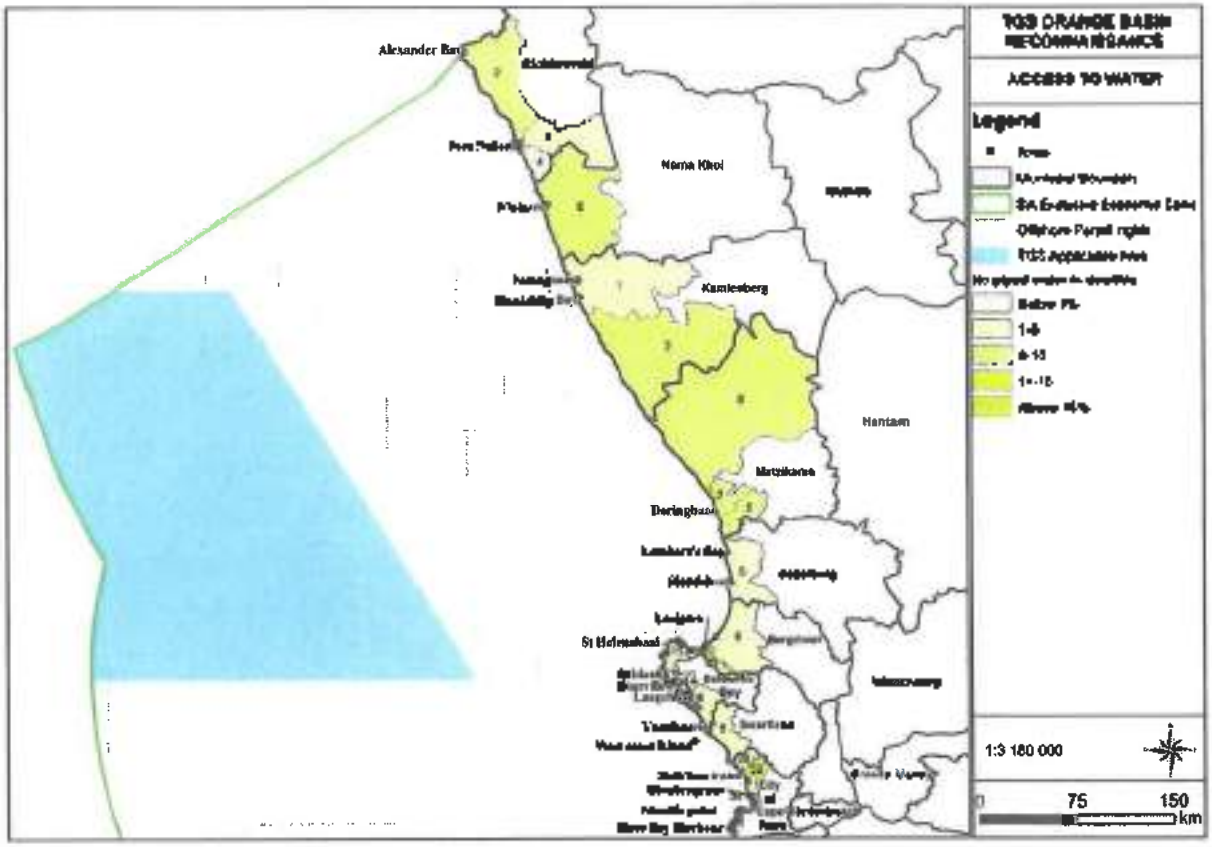
Access to piped water, electricity and sanitation relate to the domain of Living Environment Deprivation as identified by Noble et al (2006). Most households get their water from a regional or local water scheme, with the lowest incidence in Ward 1 of the Kamieskroon Local Municipality where Hondeklip Bay is located (Figure 17).

Figure 17: Proportion of households that does not get water from a regional or local water scheme (shown in percentage, source: Census 2011).



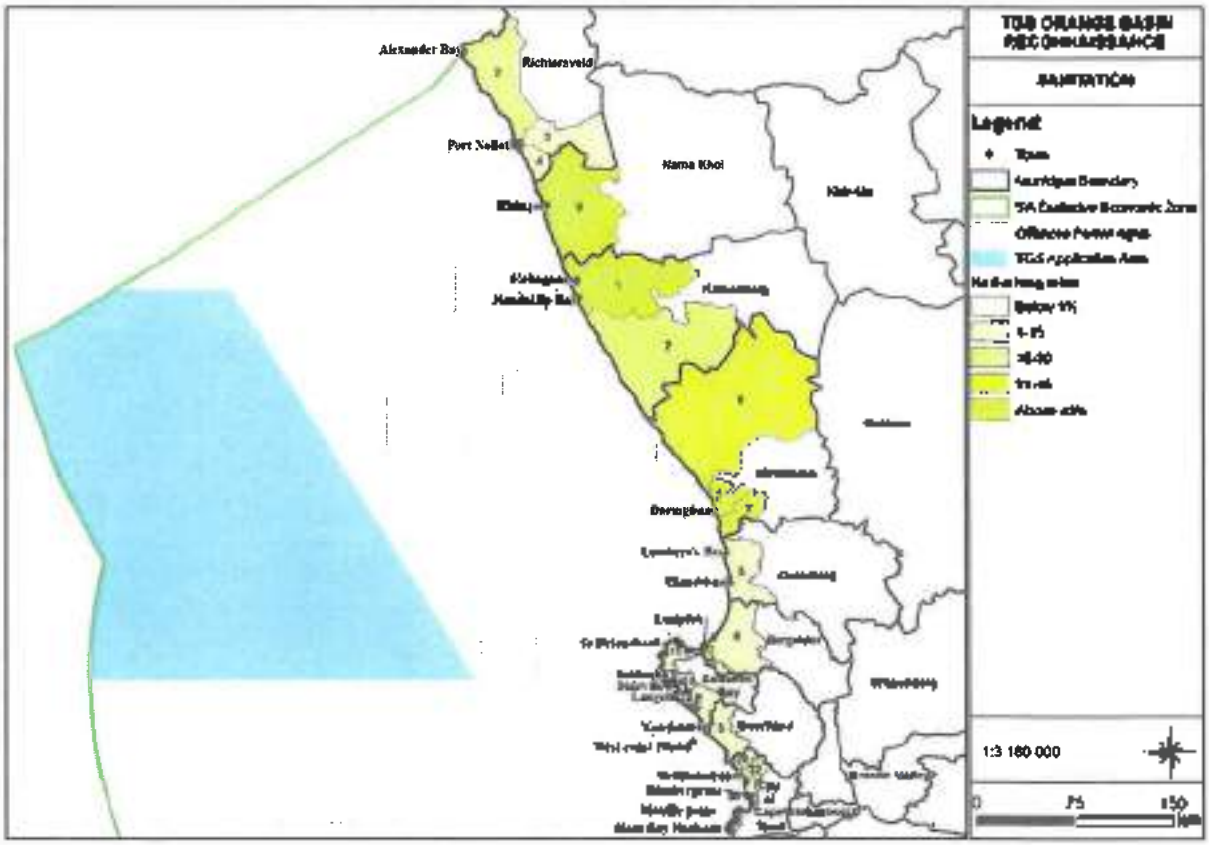
The incidence of access to piped water inside the dwelling varies and tend to be lower in the Northern Cape municipalities (Figure 18).

Figure 18: Proportion of households that does not have piped water in the dwelling (shown in percentage, source: Census 2011).



Access to a flush toilet is in general lower in the Northern Cape Municipalities (Figure 19).

Figure 19: Proportion of households that does not have a flush toilet (shown in percentage, source: Census 2011).



5.2.9 Energy

Electricity is seen as the preferred lighting source (Noble et al, 2006) and the lack thereof should thus be considered a deprivation. Even though electricity as an energy source may be available, the choice of energy for cooking may be dependent on other factors such as cost. The majority of households have access to electricity for lighting purposes (Figure 20) but a lower proportion use electricity for heating (Figure 21) and cooking (Figure 22) purposes.

Figure 20: Proportion of households that use paraffin, candles, wood or nothing for lighting purposes (shown in percentage, source: Census 2011).

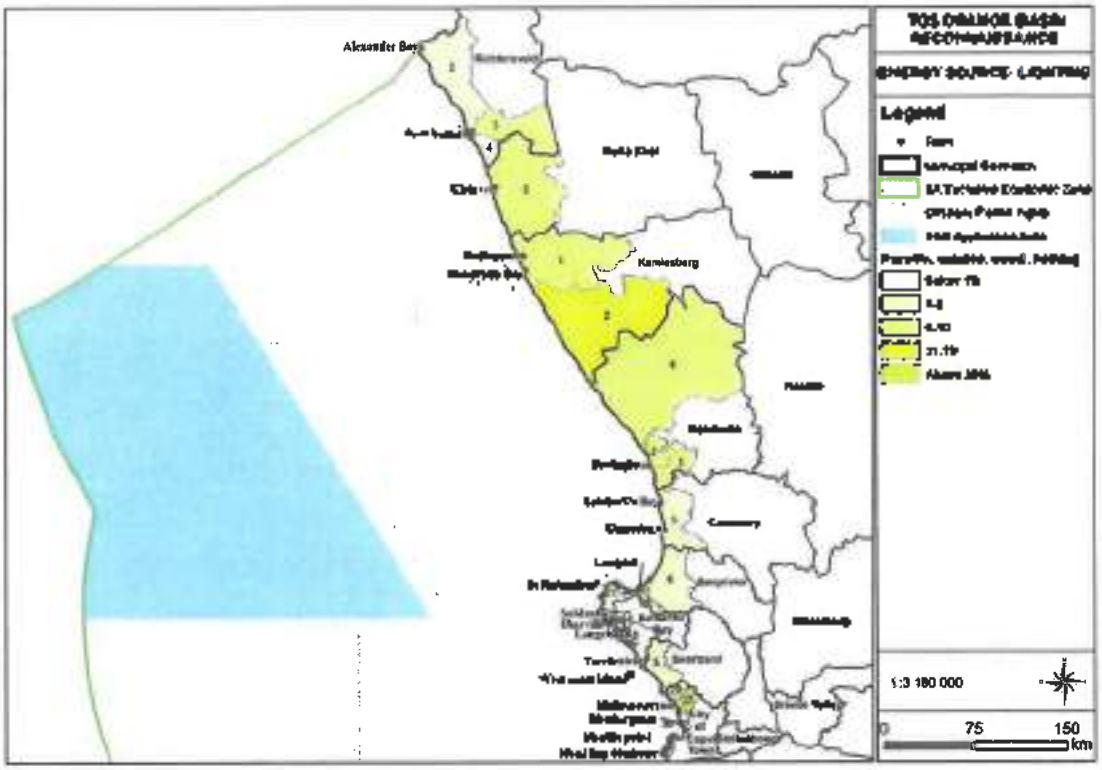


Figure 21: Proportion of households that use paraffin, wood, coal, dung or something else for heating purposes (shown in percentage, source: Census 2011).

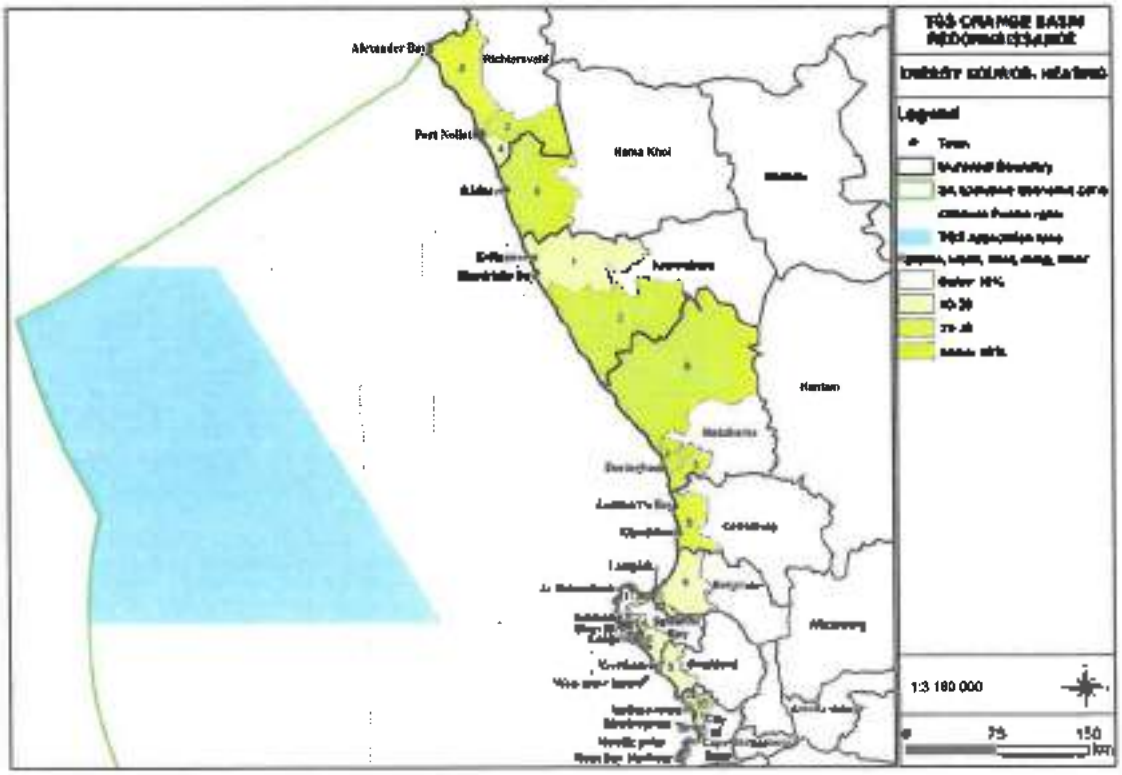

Figure 22: Proportion of households that use paraffin, wood, coal, dung or something else for cooking purposes (shown in percentage, source: Census 2011).

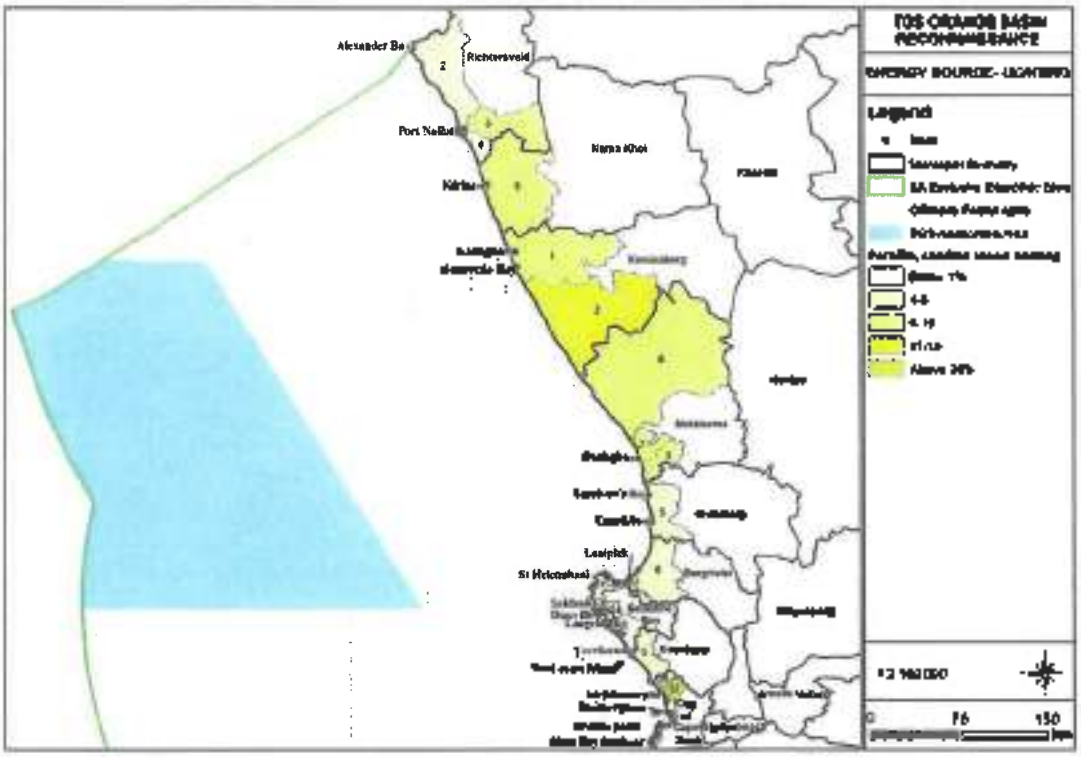


6 Stakeholder Identification and Analysis

6.1 Approach

Stakeholders include all individuals and groups who are affected by, or can affect, a given operation. Stakeholders consist of individuals, interest groups and organizations (Vanclay, Esteves, Aucamp & Franks, 2015). Stakeholder analysis is a deliberate process of identifying all stakeholders of a project - the individuals and groups that are likely to impact or be impacted by it - and understanding their concerns about the project and/or relationship with it (Vanclay et al, 2015). Stakeholder analysis assists the proponent with understanding the local cultural and political context. It is acknowledged that different stakeholder groups have different interests, and that there are individual differences within stakeholder groups. The purpose of this section of the report is to introduce the stakeholder groups that will be affected by the proposed projects. The following stakeholder groups were identified and their interest in the projects will be discussed briefly in the section below.

6.2 List of stakeholders

The following stakeholders that may have an interest in or affected by the proposed TGS seismic survey project have been identified:

Figure 23: Detail of Stakeholder Groups.

Stakeholder Grouping	Organisation
Internal Stakeholders	
TGS Geophysical Company (UK) Ltd	TGS Staff involved with the project
Seiche	Seiche Staff involved with the project
Government	
Governmental departments and directorates	• Western Cape Provincial Government • Northern Cape Provincial Government • Petroleum Agency of South Africa • Department of Environment, Forestry and Fisheries • Department of Mineral Resources and Energy • South African Navy Hydrographic Office (SANHO) • Namakwa District Municipality • West Coast District Municipality • City of Cape Town Metropolitan Municipality • Richtersveld Local Municipality • Nama Khoi Local Municipality • Kamiesberg Local Municipality • Matzikama Local Municipality

Stakeholder Grouping	Organisation
	• Cederberg Local Municipality • Bergrivier Local Municipality • Saldanha Bay Local Municipality • Swartland Local Municipality • South African Heritage Resources Agency (SAHRA)
State-owned entities and regulators	• Transnet National Ports Authority • South African Maritime Safety Authority
Business	
Fishing industry	Fishing industry associations Commercial fishing sectors: demersal trawl, midwater trawl, demersal hake longline, demersal shark longline, small pelagic purse-seine, large pelagic longline, tuna pole-line, traditional line fish, West Coast rock lobster, small-scale fisheries, beach-seine and gillnet fisheries (netfish), fisheries research
Petroleum and Gas industry	Various companies that have expressed interest in oil or gas exploration in the West Coast area Companies conducting seismic surveys
Other industries	Industries providing support services such as equipment, fuel, accommodation, meals and other supplies
Environmental	
Environmental interest groups	Green Connection Coastal Links We Are South Africans Other relevant environmental interest groups
Societal	
Social Organizations	Masifundise Development Trust Small-scale fisheries cooperatives such as Aukatowa small scale fisheries cooperative Small-scale fishing communities such as Steenbergs Cove ABALOBI Coastal Justice Network Community forums (e.g., employment, youth)
Residents/ Community	
Local coastal communities	Hout Bay, Saldanha Bay, St Helena Bay, Lambert's Bay, Hondeklip Bay, Port Nolloth, Velddrif, Paternoster, Jacobsbaai, Langebaan, Grotto Bay, Elands Bay, Strandfontein, Doringbaai
Local indigenous people	Nama, Khoi and San groups, including Cochoqua Tribal House, the Gurlqua Tribe and the Katz Korana Royal House

The identified level of interest of each stakeholder helps assist with designing the stakeholder engagement strategy for the project, and to decide how much time to devote to engaging with each stakeholder or group. The engagement levels required for each group of stakeholders as revealed through this analysis may be more than consultation, for example they may include partnerships, involvement in community

8403

development plans or community monitoring, strategic planning, or any other activity. Knowing the needs, issues and expectations of affected stakeholders assist with building and retaining good relationships with them, and with managing their expectations.

Table 5 below plots the stakeholders according to their ability to influence the company's activities (horizontal axis) and the degree to which they are affected by the proposed TGS activities, whether the impact is social, economic or environmental (vertical axis). In instances where the impact or influence is potentially significant individual stakeholder groups/organisations have been used. All other groupings are used in general.

Table 5: Stakeholder matrix.

Degree to which they are impacted on				
	High	Local coastal communities Local indigenous people	Fishing industry	TGS Geodata UK Ltd Saiche Petroleum and Gas industry
	Medium		Other industries Environmental interest groups Social Organizations	Governmental departments and directorates State-owned entities and regulators
	Low			
		Low	Medium	High
		Ability to influence company's activities		

When considering the project affected stakeholders it is important to consider the potential impacts after the seismic surveys are conducted. The stakeholders that will be impacted on most but have the least ability to influence the company's activities are local coastal communities and indigenous people, who is also seen as the most vulnerable group. Their fears about future impacts and uncertainty about the potential impacts on their livelihoods are already causing an impact on their emotional and physical wellbeing. There is a power imbalance between TGS and the local communities. It is therefore of great importance that TGS and the local communities

communicate frequently in an open and honest manner to avoid a standoff. Communities are supported by environmental and social interest organisation, and these organisations have the ability to mobilise community activists and fund potential court cases.

The community perception is that the government has already decided that it will allow this and similar projects to continue. The government is seen as a powerful stakeholder with significant ability to influence the decision-making process.

The placement of stakeholders in the stakeholder matrix may change with time, and it should be revisited frequently.

6.3 Local Indigenous people

South Africa has many different cultural groupings, among which the Khoisan are regarded as the original inhabitants of South Africa. This is not a homogenous group, and consists of smaller groups such as the Khoi, San, Nama and Griekwa. This group were of the first South Africans to experience the brutality of colonial suppression by the Portuguese under the leadership of Bartholomew Diaz in 1488 (Klaasen, 2018). In 1657 the first farms were taken from them and given to the Dutch settlers. For the Khoisan, land was not a commodity, but an integral part of their identity. Land was not for the possession of any one person, but for the use of all living there, even if it did not belong to the original group within that particular territory. Different worldviews regarding land caused great conflict. The land issue and identity of the Khoisan remained a contentious point right through the colonial and apartheid eras. The Khoisan were excluded through the controversial Restitution of Land Rights Act in 1994, as this only applied to land that were dispossessed after 1913. Their extended period of oppression excluded them from land claims, and as a result they were excluded from the reconciliation process post-apartheid. Nowhere in South Africa's Constitution of 1996 was there any space for groups like the Khoisan to reclaim dispossessed land. For the Khoisan land have both material and spiritual significance. The historical land issues are of great significance for the coastal communities.

5928

The Khoisan's approach to culture is a holistic one. Aspects such as land, identity, leadership structures, language and religion are all inter-related. The early Europeans were prejudiced towards the Khoisan as the Khoisan seemed to have missed every standard that indicated what was regarded as civilization according to European standards (Boezak, 2017): a king, jurisdiction, laws, script, arts, agriculture, money, marriage and religion. Despite scientific evidence supporting the Khoisan's claim that they are in fact South Africa's aboriginal people, the South African government has thus far not shown much political will to grant 'first nation' status to them. Their right to self-identification has been met with historical distortion and official denialism. After the abolishment of slavery, the free slaves and the Khoisan were all lumped together as the joint working classes and collectively called 'people of colour' (Boezak, 2017). Since 1948 the Apartheid regime continued to reclassify the majority of Khoisan people as 'Cape Coloured' and used the Group Areas Act of 1950 to forcefully remove them from their remaining ancestral land. The Khoisan Leadership Act is regarded as a step in the right direction, but some of the criteria are not taking into consideration their historical fragmentation.

The historical context of the Khoi and the San groups must be taken into consideration in interpreting and understanding their concerns with reference to the proposed project.

7 Social risk

Social risk is a confusing term because it has different meanings in different discourses. In the SIA/corporate project discourse, 'social risk' is a largely similar concept to 'non-technical risk' and is the preferred term (Vanclay et al, 2015). The World Bank defines social risk as "the possibility that the intervention would create, reinforce or deepen inequity and/or social conflict, or that the attitudes and actions of key stakeholders may subvert the achievement of the development objective, or that the development objective, or means to achieve it, lack ownership among key stakeholders". For the Bank, social risk is considered to be both risk (threats) to the success of the project, but also risk (social issues) created by the project, which in turn become threats to the project. In a corporate setting, social risk can be regarded as the business risks (e.g. extra costs) to the company that arise from any social impacts or social issues created by the project, such as through unforeseen costs of mitigation, future litigation and/or compensation pay-outs, worker strikes, retaliatory acts of sabotage, and reputational harm (Vanclay et al, 2015).

Non-technical risks relate to the managerial, legal, social and political issues faced by a project, in contrast to the technical risks (i.e. the physical, structural, engineering and environmental risks). Non-technical risks are potentially serious financial risks to a project because of the protest actions local communities can take, and therefore should be considered and addressed (Vanclay et al, 2015).

Risk inevitably involves a concern with good and bad outcomes (Elser, 2004). Such values will be implicit in any exchange. What any audience will be listening for is an indication of what they need to do – not simply for a prediction of what consequences may or may not happen, but also for an indication of how good or bad these consequences will be, and what they, or anyone else, is expected to do about it. The best way to communicate risk is to adopt a less didactic model of communication. It is already widely recognised that, to be effective, the communication of risks cannot be merely one-way. It must involve exchange and interaction between all parties. There are obstacles to putting such good intentions into practice. The 'experts' need to be prepared to give up not only time, but also some of their power (Elser, 2004).

The 'public' need to be willing to be engaged in the decision process and take some responsibility for the outcomes if these have been shaped to take account of their views. All this can be costly, in terms of time, patience and the risk of disappointment if not everything one wants could be achieved. The real advantage over the traditional, less consultative, approach is that the debate or discussion can focus on what people want to know and issues of value, rather than merely probability can be considered (Eiser, 2004).

Another important social factor to consider is the "social licence to operate". In 2003 Pierre Lassonde drew attention to the observation that *"Without local community support, your project is going nowhere."* He described social license as *"...the acceptance and belief by society, and specifically local communities, in the value creation of activities"*. Social licence cannot be obtained by going to a government ministry and making an application or simply paying a fee. It requires far more than money to truly become part of the communities in which a company operates (Lassonde 2003). A primary objective of gaining a social license is to minimize project risk. *"Successful operations require the support of the communities in which they operate now, and in the future, to ensure continued access to land and resources"* (Render 2005). The social license to operate can be further described as the degree of match between stakeholders' individual expectations of corporate behaviour and companies' actual behaviour.

Seismic surveys are currently a controversial and political subject in South Africa. On 1 September 2022 there was a high court ruling against Shell conducting seismic surveys. The ruling found that coastal communities were not properly consulted (Judgement on Sustaining the Wild Coast vs Minister of Mineral Resources and Energy and others, 1 Sept 2022). The debate about the potential impacts of seismic surveys has been ongoing and in the public domain for the last couple of years but intensifying in the second half of 2022. For many people it is an emotional issue and goes much deeper than scientific research on potential impacts on the marine environment. For some people the core of the issue is the impact on their indigenous and culture rights, their customs and traditions and their livelihoods.

Others feel that the seismic surveys are only the first step and that it will open the door to exploration for oil and gas. They are already aware of changes in the marine environment due to existing impacts such as shipping traffic, mining in the sea, climate change and over-fishing. Their concerns are related to the potentially negative impacts associated with the oil and gas industry, especially from an environmental perspective and the impact that using oil and gas will have on climate change. They feel that South Africa must move away from fossil fuels and act in line with the government's policies and international commitments in this regard. There are also people with the opinion that a developing country like South Africa cannot afford to not explore for oil and gas. Their feeling is that the energy transition will take some time, and that oil and gas are better than coal mines.

It is a contentious issue that can potentially cause damage to the social fabric of local communities, but also lead to civil unrest and reputational damage. From a social perspective these social risks must be highlighted. In the current socio-economic environment associated with the project area, there are significant non-technical risks associated with seismic surveys, irrespective of the company that will conduct the survey.

Table 6: Summary of potential social risks for the proposed project

Risk	Source	Motivation
Opposition to the project through appeals and court cases causing a significant delay in the process	Local indigenous communities and fishers Environmental NGOs Social Justice groups	During the SIA consultation process and as seen in the South African press it was clear that communities will not welcome seismic surveys. There is an example of a community winning a court case against a company wanting to do the survey. Communities may want to appeal the outcome of the EIA process and will resort to legal means if required because they know that resources are available to them from NGOs. These appeals and legal processes may cause a significant delay in the authorisation process which will have knock on effects.
Damage to corporate reputation	Local indigenous communities and fishers	TGS's corporate reputation can be damaged if communities feel that the process has not been conducted in what the communities see as a meaningful manner. Due to historical tension

		between some of the communities and another company doing seismic surveys that has attracted media attention in the past, there is a chance that this may be associated with TGS as many community members do not distinguish between the different surveying companies. This may impact TGS on an international level, as rights groups may be concerned about grassroots impacts, human rights and social and environmental justice, and the shares are influenced negatively.
Lack of social license to operate	Local indigenous communities and fishers Environmental NGO's Social Justice groups	Given the media attention surrounding the Shell ruling in September 2022 and the court interdict against Searcher in March 2022 there is a general mistrust against any company that want to conduct seismic surveys. Communities demand meaningful consultation, which go beyond the requirements of an EIA process. They want to feel that they can make informed decisions and have sufficient time to digest the technical information. Community members expressed misgivings about the government and its ability to protect their interest. They feel that the decision to support the application has already been made.
Community protests and potential for civil unrest.	Local indigenous communities and fishers	Communities feel angry and disempowered. They do not differentiate between the different companies that apply for seismic surveys. They see a different face standing in front of them, sharing similar information, but never providing answers to their questions. They feel that they are not listened to and disregarded. Several coastal communities expressed their frustration. The communities communicate with each other via WhatsApp groups, and there is a strong possibility of social mobilisation that can lead to civil unrest and worse case scenario to violent protests.

Social risk's population-based nature sets it apart from traditional risk events such as cyberattacks, workplace safety incidents, and natural disasters. Traditional risk events impact a distinct set of people, while social risk can impact broad segments of society.

Social risk has five characteristics (Ludke, 2021):

1438

- **Human.** Traditional forms of risk most often manifest themselves because of a discrete event or incident. Social risk is built on who we are as human beings and shaped by socio-economic status, social mobility, community environment and mental health.

- **Dynamic.** Social risk is always evolving and formed by how people react to events and ideas. For example, social risk is not necessarily the pervasive nature of socio-economic inequalities in the global economy, it is how the population react to these inequalities

- **Dispersed.** Social risk is a consequence of today's connected society where nearly everyone has the ability to increase their voice through technology and networks of family, friends, colleagues, and social media followers.

- **Distinctive.** Social risk is unique to each organization because it forms as humans organically react to events and ideas, no two social risk events are alike.

- **Scalable.** Social media platforms amplify public conversations. This accelerates social risk as it can scale very quickly from an isolated idea or conversation into a broader movement.

If TGS choose to identify and mitigate social risk, the following general recommendations should be considered:

- **Create an ecosystem of diverse partners.** A diverse ecosystem will create an "early warning system" to help identify social risk before it manifests as a threat or crisis—provided you stay engaged with this ecosystem in a genuine dialogue.

- **Ask, don't tell.** When developing a social risk management strategy, getting honest feedback can help you avoid pitfalls and build credibility. Similar to engaging partners, this must be approached by listening rather than telling.

- **Communicate constantly**. In an age of social risk, communicating is not about pushing information to audiences. Rather, it is a methodical approach to all facets of a communications strategy that fosters dialogue.

- **Act with humanity**. Social risk is driven by human emotions that must be respected and appreciated.

Addressing social risk requires looking at its causes from a systemic standpoint, not on an event-by-event basis. The solutions must be focused on the same societal level as its causes, including poverty, injustice, inequality, or misinformation. Social risk touches all of society, and it comes from the perceptions and beliefs all humans have.

8 Description of potential impacts

8.1 Social Impact Assessment

> *"Almost all projects almost always cause almost all impacts. Therefore, more important than predicting impacts is having on-going monitoring and adaptive management."* Frank Vanclay

Considering the statement above, it must be considered that some social impacts will not be discussed in detail and that the focus will be on the most severe impacts. Nevertheless, it must be considered that the social environment is dynamic and adapts to change. The focus should be on the active management of social impacts rather than on the prediction and once-off mitigation thereof. Successful mitigation and management of social impacts requires long-term commitment and involvement and should form part of the strategic planning and management of the project until decommissioning. Suggestions for the management of social impacts are included in the report in the form of a social impact management plan (SIMP). The implementation of the relevant management suggestions should start as soon as possible since the social impacts of the project started when the project was announced. Another important consideration in this project is the social context in which it will be executed. Impacts are assessed from a community perspective, and where it will influence a specific group of stakeholders it will be indicated as such. An attempt was made to simplify the impact assessment and to focus on aspects that can aid the decision-making process.

Social impacts are the result of social change, and to fully understand the potential impacts it is important to know the impact pathways. A social change process is a discreet, observable, and describable process that changes the characteristics of a society, taking place regardless of the societal context (that is, independent of specific groups, religions etc.). Social change processes can be measured objectively. The way in which social change processes are perceived, given meaning, or valued, depend on the social context in which various societal groups act. Some groups in society are able to adapt quickly and exploit the opportunities of a new situation. Others (e.g. vulnerable groups) are less able to adapt, and will bear most of the negative

consequences of change. These social change processes may, in certain circumstances and depending on the context, lead to the experience of social impacts. Social impacts are therefore completely context dependent (Vanclay, 2003).

8.2 Impact assessment criteria

It must be stated that the impact tables and ratings were adapted from the environmental sciences and that it is not always possible to compartmentalise the social impacts. For the sake of consistency this has been attempted, but it is not innate to social sciences. Allowance for the changing and adaptive nature of social impacts should be made when interpreting the impact tables.

The rating criteria used in determining the significance ratings are summarised in the tables below:

Figure 24: Criteria for determination of impact consequence.

Aspect	Score	Definition
Nature	- 1	Likely to result in a negative/ detrimental impact
	+1	Likely to result in a positive/ beneficial impact
Extent	1	Activity (i.e. limited to the area applicable to the specific activity)
	2	Site (i.e. within the development property boundary),
	3	Local (i.e. the area within 5 km of the site),
	4	Regional (i.e. extends between 5 and 50 km from the site
	5	Provincial / National (i.e. extends beyond 50 km from the site)
Duration	1	Immediate (<1 year)
	2	Short term (1-5 years),
	3	Medium term (6-15 years),
	4	Long term (the impact will cease after the operational life span of the project),
	5	Permanent (no mitigation measure of natural process will reduce the impact after construction).
Magnitude/ Intensity	1	Minor (where the impact affects the environment in such a way that natural, cultural and social functions and processes are not affected),
	2	Low (where the impact affects the environment in such a way that natural, cultural and social functions and processes are slightly affected),
	3	Moderate (where the affected environment is altered but natural, cultural and social functions and processes continue albeit in a modified way),
	4	High (where natural, cultural or social functions or processes are altered to the extent that it will temporarily cease), or

5428

	5	Very high / don't know (where natural, cultural or social functions or processes are altered to the extent that it will permanently cease).
Reversibility	1	Impact is reversible without any time and cost.
	2	Impact is reversible without incurring significant time and cost.
	3	Impact is reversible only by incurring significant time and cost.
	4	Impact is reversible only by incurring prohibitively high time and cost.
	5	Irreversible impact

Figure 25: Probability scoring.

Aspect	Score	Definition
	1	Improbable (the possibility of the impact materialising is very low as a result of design, historic experience, or implementation of adequate corrective actions; <25%),
	2	Low probability (there is a possibility that the impact will occur; >25% and <50%),
	3	Medium probability (the impact may occur; >50% and <75%),
	4	High probability (it is most likely that the impact will occur- > 75% probability), or
	5	Definite (the impact will occur),

Figure 26: Criteria for the determination of prioritisation.

Aspect	Score	Definition
Cumulative impact (CI)	Low (1)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is unlikely that the impact will result in spatial and temporal cumulative change.
	Medium (2)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is probable that the impact will result in spatial and temporal cumulative change.
	High (3)	Considering the potential incremental, interactive, sequential, and synergistic cumulative impacts, it is highly probable/definite that the impact will result in spatial and temporal cumulative change.
Irreplaceable loss of resources (LR)	Low (1)	Where the impact is unlikely to result in irreplaceable loss of resources.
	Medium (2)	Where the impact may result in the irreplaceable loss (cannot be replaced or substituted) of resources but the value (services and/or functions) of these resources is limited.
	High (3)	Where the impact may result in the irreplaceable loss of resources of high value (services and/or functions).
Degree of Confidence	Low	<30% certain of impact prediction
	Medium	>30% and <60% certain of impact prediction
	High	>60% certain of impact prediction

5628

8.3 Social impacts and mitigation

In this section each impact will be described. The project will not have a construction phase and the mitigation measures for each impact that are relevant will be discussed at the end of the section.

8.3.1 Uncertainty

The fishing communities are uncertain about the impact that the seismic survey will have on their livelihoods. They feel that there is not enough information available to them to determine whether the surveys will have an impact on their activities. In the past year a number of companies approached them to participate in EIA processes about seismic surveys. They want to have some definitive answers about the potential impacts from specialists. They would like to engage with them for more than two hours to make sure that they understand exactly what the project entails and what the potential impacts are. Only then will they be able to make informed decisions. The fishing communities have made a living from the sea for hundreds of years and they have learned how to read the ocean and the weather to know where and when fish are moving. They are concerned that the surveys could disrupt the behaviour of snoek (that is endemic to the area and a major source of income) and other fish that they rely on. They have noticed changes in the patterns of the fish they catch due to industrial activities in the past. Some examples are the potato factory in Lambert's Bay that discharges warm water in the sea and the coffer dams constructed by the diamond mines. After a previous seismic survey at the Wild Coast, people observed dead Black Steenbras that were reported to have protruding nostrils. Furthermore, they also noticed changes in the patterns of the fish that they ascribed to climate change. For the fishing communities, the sea is an integral part of their identity, and they possess local knowledge that are not yet written up in scientific reports.

The marine fauna and fisheries reports indicate that low to negligible impacts on marine life and that all the impacts are reversible. However, the communities are not convinced. According to them, the fish can either go deeper in the sea to get away of the source of noise, which would be a tragedy for them, or they can go closer to the

shore, which would be beneficial for them. They feel that no-one can predict with certainty how the fish would respond to the noise, just that they would try to move away from the source.

The impact of seismic surveys on the catchability of marine fish remains a contentious issue for communities, with some claims that seismic surveys may negatively affect catch rates. However, little empirical evidence exists to quantify the impact or identify the mechanisms of such impact. The communities feel that there is simply not sufficient data available to negate or substantiate these claims and much more research on the topic is needed, especially from a local perspective. The consensus seems to be that there is a great knowledge gap in this regard. Community members feel that companies doing seismic surveys or those who have an interest in the data obtained through seismic surveys can make a great contribution to scientific knowledge of this field by funding independent research on the topic in South African waters.

People's livelihoods are already impacted by external factors such as fishing quotas, climate change, commercial over-fishing, mining in the sea and the recent Covid pandemic. They fear that the seismic surveys will contribute to an already dire situation and be a tipping point that will render them helpless and without their last source of income. They see seismic surveys as a gateway to oil and gas exploration and are concerned about the potential impacts that the results of the seismic surveys can unlock. There is a high level of uncertainty about the future of the ocean, which causes great concern and distress amongst the fishing communities, especially because the uncertainty is related to their livelihoods, and they are already struggling to make ends meet. Uncertainty also takes its toll on people psychologically and may result in mental health issues for some people in the long run.

8.3.2 Further marginalisation of vulnerable groups

In South Africa, claims for and access to natural resources are deeply embedded in people's histories, identities, and livelihood experiences. As in the case of land, access to and rights over fisheries resources is a highly contested issue where individuals and communities have equated such rights with human rights (Williams,2021).

Globally, fishing activities for many communities sees strong cultural and traditional links spanning many generations, and its value is seen beyond the means of earning a living (i.e. economic values). Whilst fishing takes place at sea, other activities related to fishing such as boat and net maintenance, the selling and trading of fish, etc. take place on land. Men and women are involved in fishing and indigenous knowledge and skills such as gutting and cleaning fish, reading the sea, and finding fish are transferred from generation to generation. The activities associated with fishing create a particular identity or characterise an area as a result of these activities (Williams,2021). Fishing is part of the cultural identity of the people living in fishing villages on the West Coast.

Many of the people on the West Coast belong to the Nama, Khoi or San people. Most of the Khoi people were traditionally cattle or sheep herders, while the San people were traditionally hunters and gatherers (www.san.org). They were the first inhabitants of southern Africa and one of the earliest distinct groups of homo sapiens. They have endured centuries of gradual dispossession at the hands of waves of new settlers, including the Bantu, whose descendants make up most of the black population of South Africa (https://foreignpolicy.com/2018/10/19/south-africas-first-nations-have-been-forgotten-apartheid-khoisan-indigenous-rights-land-reform/).
The process of land distribution instituted by the Government since 1994 has largely excluded the Khoi and the San people, as the government has not acknowledged them as the country's first peoples and their land was mostly taken before the apartheid era. There is a growing movement of indigenous activists that believe it is time to rightfully claim their traditional land.

One of the Khoi and San's biggest challenges is the racial classification system used in South Africa. They are being classified as 'Coloured' - a label that was used during Apartheid for citizens that did not fit the binary race model and included mixed-race children and Afrikaans-speaking non-whites. This categorisation condemned much of the Khoi and San's history to oblivion and facilitated the appropriation of their land. It excluded them from land restitution as it was conceived to be a benefit to black South Africans, and they were not considered to be black. As such the Khoi and San are

considered to be very vulnerable and marginalised groups. Being marginalised means that they may easily be overlooked by corporate groups or businesses unfamiliar with the local history. Their needs, their views and even themselves as a stakeholder group can easily be omitted – both intentionally and unintentionally. In a previous application for a seismic survey by another company in the area the Khoi and San felt that they were not consulted with. Therefore, they are sceptic about the intentions of any company doing seismic surveying. They felt that they were discriminated against by not being consulted during that previous application, deepening their status as marginalised groups, and causing distraught to them as groups. Many of the fishers are of Khoi and San descendance, and they feel that they simply cannot win in any situation – whether it is fishing rights, land rights or culture identity.

With increasing interest in the West Coast area by seismic surveyors, which is viewed as the precursor for oil and gas companies to start developing the area, these communities risk increased marginalisation and an increase in vulnerability with every application where their voices are not being heard. They feel that currently they need to fight to make their voices heard. They have been using legal avenues, as they feel that just speaking up is not effective and has failed to give them the desired outcomes. Communities feel that their cultural heritage is threatened.

The San has published the San Code of Research Ethics that provides a guideline for researchers and companies that want to work in their sphere of influence on how to conduct themselves and how to interact with the San. From their perspective, an EIA application is also viewed as a form of research. This guideline can be applied to the Khoi and other people in the fishing communities as well. The San Code of Research Ethics is based on:

- Respect for individuals, community and culture;
- Honesty;
- Justice and fairness;
- Care; and
- Process (following San research protocol).

The San Code of Research Ethics states that lack of care can be demonstrated by talking down to communities, confusing them with complicated scientific language, or

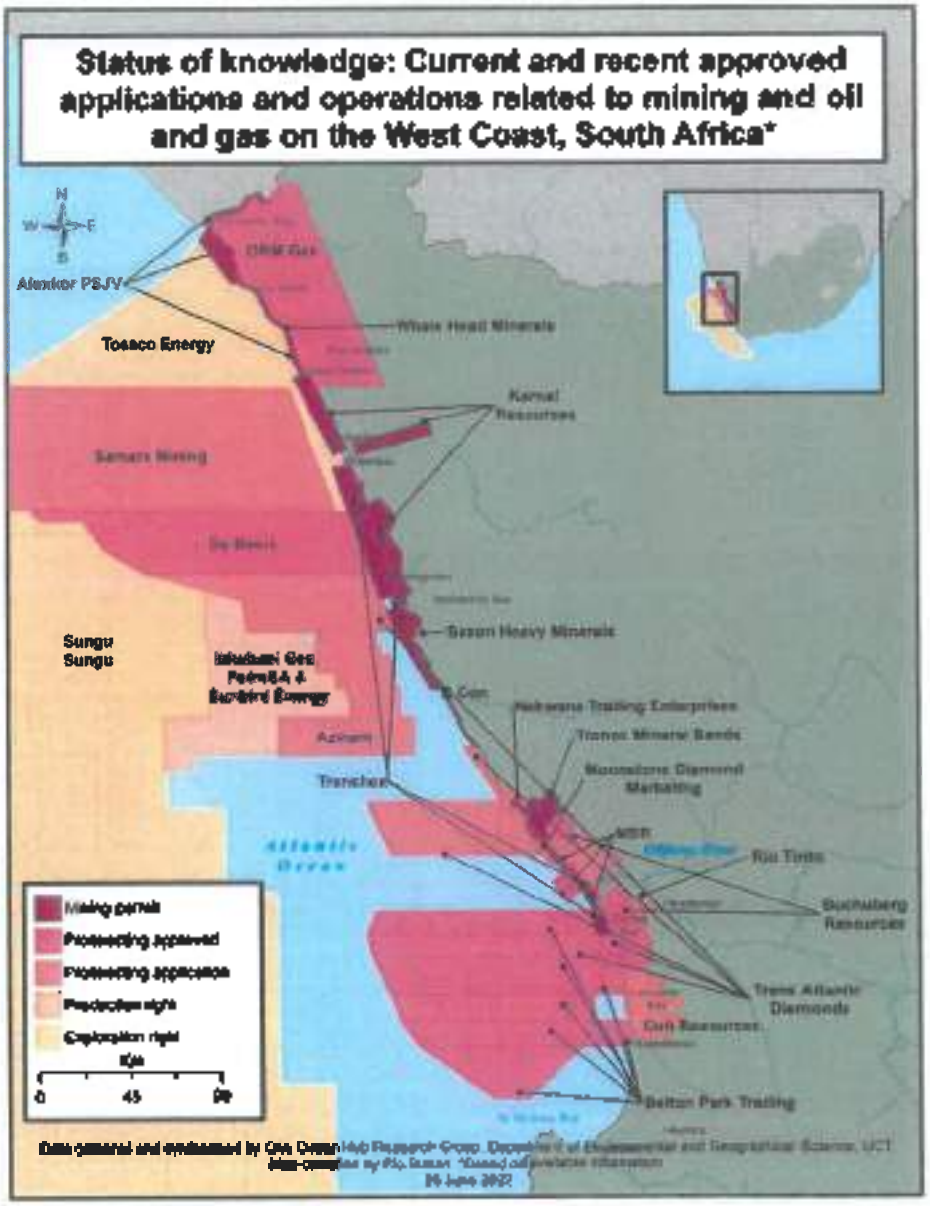
3209

treating communities as ignorant. It further states that a lack of care is also represented by failing to ensure that something is left behind that improves the live of the San.

8.3.3 Concerns about cumulative impacts

A great source of concern for the fishing communities is the effect of cumulative impacts on their livelihoods and sense and spirit of place. There are a number of applications in process as well as approved applications relating to seismic surveys, mining, and oil and gas exploration in the West Coast area. There are also existing mining activities, significant shipping traffic and commercial fishing taking place in the ocean. The concern is that at some stage a tipping point will be reach where the marine life no longer recovers from the activities in the ocean or take a long time to recover to the extent that it would no longer be viable to make a living from the sea in those areas. In Norway small-scale fishing successfully co-exists with oil extraction in the ocean, but for the small-scale fishers on the West Coast, it remains uncertain to what extent it will be the case for them as well. Although cumulative impacts are assessed as part of the EIA process, there are limitations associated with budgets, timeframes, and access to resources. The competent authorities have a legal and moral duty to consider the cumulative impacts of the activities taking place and are planned to take place on the livelihoods and heritage of the vulnerable communities in the area from a strategic perspective. There must be a balance between the contribution these activities can make to South Africa's economy and sustaining the livelihoods of the vulnerable communities on the West Coast. The communities are clear that they do not necessarily want to stop development, they want to make sure that their livelihoods and heritage are protected, and that the rights of future generations will not be compromised. Once these have been affected negatively, it may not be possible to easily undo the damage.

Figure 27: Current and recently approved applications and operations relating to mining, oil and gas.



8.3.4 Perceived impact on livelihoods

A livelihood refers to the way of life of a person or household and how they make a living, in particular, how they secure the basic necessities of life, e.g., their food, water, shelter and clothing, and live in the community (Vanclay et al., 2015). The coastal communities in the area of interest are mostly fishing communities that make their livelihoods from the sea and have been doing so for generations. They rely on the ocean for food and economic security, as well as their identity and heritage. They

know how to make a living from the sea. If it is no longer possible for them to make a living from the sea, or if their ability to make a living from the sea is reduced it will result in a great increase in poverty in the area as there are very limited alternative options for them to make a livelihood. Their skill sets are strongly linked to the sea and cannot be transferred to other economic activities without skills development, training activities and the economic diversification of the area. Men and women rely on the sea for their livelihoods, and it is closely linked to the culture and identity of the people. This makes these communities extremely vulnerable. Furthermore, an increase in poverty in the area will place an additional burden on tax payers.

The small-scale fishers can travel approximately 15 nautical miles offshore with their boats. Some of them have indicated that they already sometimes need to go further to be able to catch enough fish, which is not only more expensive for them in terms of the diesel required for their boats, but it is also more dangerous. In the mining areas around Port Nolloth they are struggling to get access to the sea and the areas where they are allowed to fish are getting smaller.

Livelihoods are already compromised due to the fishing quota system, over-fishing, lack of employment opportunities, pollution, effects of climate change and the recent Covid 19 pandemic. However, with reference to the assessment of the impacts on the catch rates from the fisheries assessment undertaken by CapMarine (2022), the impact on livelihoods is not because of the actual impact on catch rates, but because of the perceived impact of the oil/gas industry on fishing industry.

8.3.5 Impacts on sense and spirit of place

Sense of place refers to an individual's personal relationship with his/her local environment, both social and natural, which the individual experiences in his/her everyday daily life (Vanclay et al, 2015). It is highly personal, and once it is affected, it cannot be restored. It is also difficult to quantify. The environmental philosopher Glenn Albrecht noted a consistent theme of distress caused by coal mining in Australia by the assault on the people's sense of identity, place, belonging, control, and good health. He identified a melancholia from the loss of solace and comfort connected with their home which he termed 'solastalgia' – a form of homesickness that one gets

when one is still at 'home' associated with the major project impacts they experienced (Albrecht et al, 2007). Social impacts can therefore range from significant health impacts to the loss of a cherished landscape and associated loss of a sense of place.

Spirit of place refers to the unique, distinctive, and cherished aspects of a place. Whereas 'sense of place' is the personal feelings an individual has about a place, spirit of place refers the inherent characteristics of the place (Vanclay et al, 2015). In this case the spirit of place includes the ocean and the properties assigned to it.

Many things can impact on a person's perception of sense of place. For the fishing communities the ocean is an integral part of their being, therefore anything that is perceived to potentially harm the ocean would also cause harm to them. The ocean provides them with food and thus keeping them from starvation. For many the sea is a sacred place. Its water has healing powers that take care of the sick. Many loved ones have given their lives to the ocean while they were out trying to make a living, and their remains have never been found. The sea kept their bones, making the ocean the graveyard where their loved one's rest. For some people the thought of disturbance in the sea causes great distress. The heritage aspects relating to this are discussed in the heritage impact assessment report. Although this cultural and spiritual connection with the sea might be difficult to understand for outsiders, it must be respected as a cultural right.

8.3.6 Impacts on the social licence to operate

Social licence to operate (SLO) is a popular expression to imply that the acceptance of the community is also necessary for a project to be successful. It appears as if TGS does not currently have social licence to operate in the fishing communities. Based on the events surrounding previous applications and recent reports about seismic surveys in the media, the communities expressed that they do not trust TGS or any other company conducting seismic surveys. Applications for seismic surveys and community opposition to these surveys have been widely reported and debated in the media during the last year (Compare News 24, 13 Jan 2022; Mail and Guardian, 20 Jan 2022; Eye Witness News, 1 September 2022 amongst others). Numerous NGOs specialising in social and environmental justice have aligned with communities and

228

assist them with opposing seismic surveys. Some community members think that seismic surveys are opening the door for oil and gas exploration, which is a great concern for them, mostly due to the anticipated impacts on their livelihoods.

Given that there are a number of applications for seismic surveys in the Orange Basin, and that each application is subjected to a Basic Assessment process, communities are confused and reaching saturation regarding consultation. From their perspective, with each new application, it is a new face standing in front of them, from a new company, but "basically everyone wants the same thing". Communities do not distinguish between different seismic survey companies. They feel as if their questions are not answered, and concerns are not addressed – each consulting firm just repeat the same technical information about what a seismic survey entails to them. Although this is not TGS's fault and they are following a prescribed legal process, it impacts on their social licence to operate and on the seismic survey industry as a whole.

The term "social fabric" embraces numerous complex and interrelated phenomena, including demographic and economic factors, behavioural issues (e.g. investment choices, political dynamics), social institutions (e.g. families), social organisations (e.g. municipalities and churches), and social networks, or relationships amongst people. The social fabric is underpinned by people's beliefs and sentiments, including a sense of belonging and identification with a particular social unit (Atkinson et al, 2017).

The social fabric in the communities have been damaged through previous negative experiences with businesses in the area. A number of factories in the greater area have closed or moved away and in the process of doing so created great hardship for the communities remaining behind. Very little severance was paid, and this aggravated the communities. Mines closed without proper rehabilitation plans. In some places, access to the areas where they earn their livelihoods are becoming increasingly restricted, especially through the activities of mining companies. This has reached a point where the communities have realised that they need to fight for the protection of their livelihoods as historically companies have in most cases not treated them fairly or with respect. It is unlikely that any company that would like to undertake an activity in the ocean will be given social licence to operate by the community. The

TGS

community have been traumatised by historical events and behaviour of companies too many times. On the other hand, there are members in the community that welcome any new development and feel that living from the sea has its limitations and would soon be impossible. The dynamics between the different groups in the community, caused by the myriad of seismic survey applications, has already done significant harm to the social fabric of the fishing communities. People with individual agendas cause conflict in the community, and given the vulnerability of the community, the dire socio-economic conditions and high levels of poverty, illiteracy and unemployment, community members are susceptible to these forms of manipulation.

> ***Example of deterioration of social fabric:***
>
> *An individual rallied the youth in the community by telling them that they will be given work by a company doing seismic surveys (that was at the time busy with their public participation process) and ask them to complete forms and sign it. The company itself is unaware of this activity. Other members of the community find out about this and informed the consultants. Older community members fear that the signatures will be used to show community support to the project. Community members that lived together in peace and harmony for years are suddenly not talking to each other, and the community is divided.*

Another aspect that affects TGS's current social license to operate negatively, is that previous applicants such as Searcher and Shell failed to conduct sufficient meaningful consultation with the small-scale fishers in the past. The MPRDA Regulations as amended in 2020 define meaningful consultation as: *consulting in good faith, in a way that gives the landowner, lawful occupier and/or interested and affected persons all the relevant information, and reasonable time and opportunity to make an informed decision regarding the impact of the proposed activities.*

The communities feel disrespected and marginalised by the processes followed up to date by previous applicants in the area. Engaging with the communities in a meaningful way, following the appropriate structures and protocols, will go a long way in improving TGS's social license to operate. It does not guarantee that the communities will accept TGS or any other company wanting to conduct seismic

surveys. It must be kept in mind that improving social license to operate takes time and effort.

8.3.7 Stakeholder fatigue and disillusionment

Signs of stakeholder fatigue are visible in the communities. Stakeholder fatigue may occur where many stakeholder initiatives have taken place in the past, especially in circumstances where they did not lead to tangible outcomes for stakeholders. There are a number of applications for seismic surveying, exploration and mining in the area that the stakeholders were invited to. The most obvious way to deal with this would be to avoid working with communities, suffering from stakeholder fatigue (Durham et al, 2014), but this is not always possible and infringe on their rights. The EIA process requires public participation and information sharing. The volume of consultation and information shared are confusing to the communities. Stakeholders start to feel overloaded, which negatively affects their willingness to participate and lessens the quality of their input. Over time only those who are deeply interested, that is strongly supportive of strongly opposing may still participate. This can hinder potential projects, and can particularly occur when the stakeholders consulted are not actively involved in decision-making. To be effective and to reduce stakeholder fatigue, engagements need to be targeted, with clear aims and results. Stakeholders need to be clear on what the goal or end benefits to themselves would be for participating. It must be kept in mind that the more stakeholders contribute their time and knowledge, the more they will expect in return from the project, so one always need to ensure that the relationship remains balanced.

Related to stakeholder fatigue is stakeholder disillusionment, which can occur during a project or can be a legacy of past involvement in stakeholder participation. Disenchantment can result from failure to manage credibility, relevance and legitimacy, particularly when communication is poor or expectations are not met. Stakeholders can feel let down from previous involvement and disenchantment can also result from failure to keep promises. A number of stakeholders have already indicated that they feel their voices don't matter and participating in all the processes are not making a difference.

FZ08

Credibility, relevance and legitimacy can be enhanced when (www.i2insights.org):

- Other invited stakeholders are considered to be appropriate;
- Stakeholders with opposing views who are included are generally respected;
- There are clear objectives;
- The processes used are transparent and seen to be appropriate;
- There is continuity in the participation, allowing relationships to be maintained, trust to be developed, and stakeholder knowledge and skills to be built on;
- Attention is paid to appropriate timing of participation processes;
- Results are delivered in a timely manner;
- The participation and communication processes are effective and ongoing throughout the application process;
- Participation is adapted to changing circumstances;
- Understandable language is used;
- The process for participation for all stakeholders is clearly stated and appropriate;
- Stakeholders feel that their interests have been understood and taken into account;
- The multiple stakeholders involved are seen to be a balanced group;
- Use unbiased facilitators where possible.

TGS can only influence what happens in their own application. By attending to issues discussed and keeping promises made to stakeholders, they give their own application process the best possible chance and make it more likely that stakeholders will participate in the future.

8.3.8 Community expectations

Not everyone in the fishing communities is opposed to the project or to oil and gas exploration. Their perceptions are that the ability to make a living from the sea is already declining. It is a hard live and they want a better life for their children. There are very limited alternative opportunities for making a livelihood and very limited job opportunities. They will support industrial development in the area if it brings opportunities for their children for employment and skills development. They want to know that they will benefit from the process that will be set in motion by the seismic

surveys. They know they will not be direct beneficiaries from the extraction of oil and gas, but that they will be the ones that pay the price. Their expectations are that the oil and gas companies will invest in these communities and assist them with creating alternative livelihoods and obtaining the necessary skills and experience in that regard. Although TGS will be doing a survey to gather data that will be utilised by oil and gas companies, and TGS's activities will be of a temporary nature, with little benefit to the locals, the communities do not distinguish between data collection and exploration or extraction. For them these companies are one and the same, and they have similar expectations of TGS.

The proposed project collects data that would be of great value for the companies interested in extracting oil and gas in the area in future. Should this happen, it would have a positive impact on the economy of South Africa, seen together with the Government's plans for the development of a new industrial port at Boegoebaai. In a country with very high unemployment levels and suffering from a recession and an energy crisis, this is seen as a positive future development by many role players. As such, the communities feel that the government supports the application, and that community consultation is simply a matter of ticking the boxes. The question of who pays the price and who gets the benefit is relevant in this context. The price that the fishing communities will pay eventually, will be high as it may have an extremely negative impact on their livelihoods with little or no benefit to them, unless measures are put in place to protect their livelihoods. It must be considered that community livelihoods are broader than just catch rates and fishing, but includes the capabilities, assets (including both material and social resources) and activities required for a means of living.

8.3.9 Social unrest

Generally, social unrest occurs when a group gathers publicly to express dissatisfaction or anger centred around a common cause and is usually accompanied by a demand for societal change. Poor socio-economic conditions caused by unemployment rates, corruption, inflation, and bad governance can contribute to social unrest. South Africa has a history of using protests to air grievances. Social

unrest is often triggered by an event or action that provokes strong feelings amongst community members.

Some of the communities are adamant that they would not allow gas or oil extraction in the area, and that includes collecting the required data from the ocean. There have already been court cases in this regard, and there are also court cases that are ongoing. Some community members have threatened with violence against surveying vessels. Others have threatened that they will take action to fight seismic surveys, in any way that they seem appropriate. This is a very emotional issue for many people and that could erupt into social unrest. Related to this is potential for conflict between community members who support the project and those that are against the project.

8.3.10 Mitigation and management

TGS's activities for this application would be of short duration if approved, and if viewed in isolation considering only technical risks as discussed in various specialist reports conducted as part of the EIA process, the impacts will be negligible. However, communities feel that there are significant gaps in the available data and from a social perspective the non-technical or social risks can potentially cause significant impacts. Although the marine fauna and fisheries specialists have indicated that the impacts on the marine fauna would be negligible, the communities, with generations of experience in the ocean, fear that the behaviour of the fish will change and that this would affect their catch rates and consequently their livelihoods. What is seen as a minor impact in a large eco-system may be experienced as a major impact by an individual. The marine fauna might not be affected greatly, but the fishing community fear that marine fauna might change its behaviour in response and that is a main concern from a social perspective.

It must be considered that from a social perspective perceived impacts (something that is believed to be a potential impact rather than something that has been established as being an actual impact) should be treated as real impacts. Perceived impacts affect how people feel about the project and how they feel and behave generally, thus perception is reality for them (Vanclay et al, 2015). While the public's assessment of risk is perceptual in nature, their fears should not be dismissed as

irrational and therefore unimportant. Living with the fear and uncertainty is an impact in itself (Burdge, 1998).

There are current impacts on the livelihoods of the communities from aspects such as pollution, shipping traffic, mining in the sea, over fishing and climate change. The cumulative impact of additional activities in the ocean where these communities earn their livelihoods is of concern to them, especially if a number of companies engage in exploration activities in the area in an unplanned manner. They urge the government to approach the matter from a strategic perspective. The strategic approach is not the responsibility of TGS but must be managed by government.

The short-term nature of the seismic reconnaissance and proximity from communities must be considered when suggesting mitigation measures. The mitigation measures suggested must be seen as building blocks for any potential further developments or activities that may be conducted by TGS in future.

1458

Figure 28: Potential mitigation for impacts on existing livelihoods.

No	Mitigation Measures	Phase	Timeframe	Responsible party for implementation	Monitoring party (frequency)	Target	Performance indicators (monitoring tool)
1	TGS should develop a community engagement protocol that is based on the San Code of Research Ethics. This should be done in consultation with the affected communities and include a communication strategy and grievance mechanism.	All phases	Commence in the planning phase and continue throughout the life of the project	TGS	Keep records of all communication with communities throughout the life of the project	Establish good relationships with fishing communities	Written community engagement protocol Communication register, social risk and incident register
2	TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. Collaboration across seismic operators with holders of hydrocarbon exploration and the industry as a whole to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study. This would quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in South African Waters. Communities should be consulted on the issues that should be researched.	All phases	Commence in the planning phase and continue throughout the life of the project	TGS	Meetings with communities. Meetings with independent research organisations	Protect the livelihoods of the fishing communities	Minutes of meetings Written agreements with independent research organisations such as universities

1459

828

3	Consult with communities on ways in which to positively contribute to the communities.	All phases	Commence in the planning phase and continue throughout the life of the project	TGS	Meetings with communities	To give something back to the communities	Minutes of meetings Written agreements with candidates
4	A representative from TGS should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist with establishing the relationship between TGS and the traditional communities. If needed, the meetings can be facilitated by an external party. This is an explicit request from community members and failing to do so will increase the reputational risk for TGS and weakens their social licence to operate further. It will also cause significant delays in the application process. Given the current socio-political conditions in the coastal communities following prescribed legal processes is not sufficient to be seen as meaningful consultation from a community perspective.	All phases	Commence in the planning phase and continue throughout the life of the project	TGS	Meetings with leadership	To ensure that there will be no misunderstanding about what meaningful consultation entails in future it will also assist with clearing up past misapprehensions	Minutes of meetings

1460

5	Assessing all cumulative impacts of the seismic survey industry on the livelihoods of communities, addressing perceptions and alleviating fear from a strategic perspective is not TGSs' responsibility and falls outside the scope of one environmental impact assessment. It is the responsibility of the relevant authorities and the industry. However, the seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign. Having meetings will not be sufficient. Participatory processes and workshops where communities can engage in experiential learning should be considered. If the seismic survey industry fails to address the community's need for education and cooperation it will result in significant delays and increase the risk for social unrest.	Before the study commence	Before the study commence	TGS to initiate discussions with the industry governing bodies.	Meetings with industry role players and relevant authorities	Ensure that communities can make informed decisions and engage in meaningful conversations about seismic surveys.	Workshops, awareness raising campaigns and community education

9 Conclusion and recommendations

TGS's activities for this application would be of short duration if approved, and if viewed in isolation considering only technical risks as discussed in various specialist reports conducted as part of the EIA process, the impacts will be negligible. However, communities feel that there are significant gaps in the available data and from a social perspective the non-technical or social risks can potentially cause significant impacts. Although the marine fauna and fisheries specialists have indicated that the impacts on the marine fauna would be negligible, the communities, with generations of experience in the ocean, fear that the behaviour of the fish will change and that this would affect their catch rates and consequently their livelihoods. What is seen as a minor impact in a large eco-system may be experienced as a major impact by an individual. The marine fauna might not be affected greatly, but the fishing community fear that marine fauna might change its behaviour in response and that is a main concern from a social perspective.

Another concern is the cumulative impact of activities in the ocean where these communities earn their livelihoods. Their fears about the tipping point where their source of livelihood does not recover from all the activities in the ocean, and they are no longer able to make their livelihood as fishing communities must be considered. Currently these communities are able to sustain themselves, although it is difficult. The communities are not against development, but they want to see it happen in a sustainable way that does not jeopardise their source of livelihood. They have already seen how their livelihoods are being affected by mining that is taking place in the sea, pollution, climate change, over fishing and businesses such as factories that come and go and often and do not leave in a socially responsible way.

TGS, as well as other companies that want to do surveys or exploration in the area, currently do not have social license to operate. A large part of this is due to a lack of meaningful consultation by previous applicants from a community perspective. If TGS or any other seismic survey company wants to proceed with the project, they will need

DE28

to engage in meaningful conversation with the communities and try to restore relationships. From a community and social risk perspective this is not negotiable.

Seismic reconnaissance projects are controversial in South Africa and has been in the news frequently in the last year. For many stakeholders it is an emotional matter, for others the potential of impacting their livelihoods is the biggest fear. There are also stakeholders that feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change. Other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. It is a complex and wicked[2] problem.

Based on the findings, the following recommendations are made:

- TGS should develop a community engagement protocol that is based on the San Code of Research Ethics. This should be done in consultation with the affected communities. This should include a communication strategy and grievance mechanism.
- TGS should contribute to assisting with collaboration on independent research on how fish species on the West Coast such as snoek respond to seismic surveying. Collaboration across seismic operators with holders of hydrocarbon exploration and the industry as a whole to collectively fund pro-active research would provide opportunity for the development and implementation of a structured and experimentally sound acoustic study. This would quantitatively inform the authorities and stakeholders of acoustic impacts to the various faunal groups in South African Waters.
- Consult with communities on potential ways in which to make a positive contribution to the communities.

[2] a **wicked problem** is a problem that is difficult or impossible to solve because of incomplete, contradictory, and changing requirements that are often difficult to recognize.

- A representative from TGS should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist with establishing the relationship between TGS and the traditional communities. Given the socio-political environment, opposition to the project and associated non-technical risks, further meaningful engagement with the leadership and communities are critical from a social perspective. Given the risk of stakeholder fatigue, it would be most beneficial if this can take place on an industry level.

- TGS should initiate discussions in their industry. The seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign. Having meetings will not be sufficient. Participatory processes and workshops where communities can engage in experiential learning should be considered. If the seismic survey industry fails to address the community's need for education and cooperation it will result in significant delays and increase the risk for social unrest.

From a social perspective it is clear that the communities and majority of local people are opposed to the project. If the project is considered in isolation, the impacts are negligible. However, the project does not happen in a vacuum, and the social environment is much wider than the footprint of the project. If the social risks and potential damage to cultural and indigenous rights are considered the impact on the social fabric of already vulnerable communities may be significant. At this stage communities feel that they cannot make informed decisions. Although all legal processes have been followed, the seismic survey industry is not moving at the pace of the community, and in the long run this will be detrimental to the industry. Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed. From a social perspective it is recommended that the project proceed subject to the mitigation measures (i.e. meaningful consultation, local research, education, and awareness raising in the

FC28

project-affected communities) forming part of the conditions for authorisation and being implemented prior to the commencement of the actual survey.

Ilse Aucamp

Social Scientist

Summary

Ilse Aucamp holds a D Phil degree in Social Work obtained from the University of Pretoria in 2015. She also have Masters' degree in Environmental Management (Cum Laude) from the Potchefstroom University for Christian Higher Education which she obtained in 2004. Prior to that she completed a BA degree in Social Work at the University of Pretoria.

Dr Aucamp is an experienced facilitator, trainer and lecturer and presents modules on social impact assessment and public participation on several short and university courses. She is past chairperson of the sections coordinating committee of the International Association for Impact Assessment (IAIA) having been section chair for the SIA section before. She has served on the National Executive Committee of IAIA's South African affiliate for a number of years. She advises the Centre for Environmental Rights on social issues, and is also on the advisory panel of the SIAhub, an international website aimed at SIA practitioners. She is a co-author of the ***Social Impact Assessment: Guidance for assessing and managing the social impacts of projects*** document published by the International Association for Impact Assessment. In 2016 and 2017 she was invited to be part of the *Expert Meeting on Non-discrimination* for the World Bank's Environmental and Social Framework. The aim of the group is to assist the World Bank with writing guidance notes for the framework on how to engage with vulnerable groups such as children, the elderly and disabled people. In addition, Dr Aucamp assisted the Government of the Seychelles with developing a SIA framework for the country.

Dr Aucamp has managed and conducted several public participation processes during her career. Dr Aucamp has conducted more than 117 social impact assessments during the last nineteen years. These include assessments on different kinds of projects, from housing developments, energy projects, transport projects, to mining and recreational projects. Her experience includes facilitation and training, strategic assessments, social management and monitoring plans and social development initiatives.

Qualifications

- 1994, BA (Social Work), University of Pretoria
- 2004, Master's degree in Environmental Management (Cum Laude), Potchefstroom University for Christian Higher Education
- 2015, D Phil (Social Work) University of Pretoria.

Registration(s)

- South African Council for Social Service Professions(Registration number: 10 – 16558)

Further training 2001-

- Introduction to SIA - Burdge
- Sustainable Livelihoods Training – Khanya Development Trust
- Achieving the full potential of SIA – Vanclay & Esteves
- Involuntary Resettlement – Appleby, Rawa & Rivas de Neffa

- Renewable energy including Soventix – De Aar 225MW Solar PV project, Mogalakwena Solar Project and Scaffal Solar.
- Port feasibility and social assessments including Oranjemund Port Feasibility Study, Expansion of the Port of Lüderitz Feasibility Study and Expansion of the Port of Saldanha SIA.
- Industrial development including Kathu Supplier Park, Sephaku Chemical Plant, Phola-Kusile Coal Conveyor, Ferrometals Storm Water Management, Uranium plant – Welkom, Hoedspruit Ethanol Plant, Saldanha Separator Plant, Babelegi Smelter and Ubombu Sugar.
- Lesotho Lowlands Bulk Water Supply Scheme (Zone 2&3)
- Residential developments including Rietvlei and Rietspruit, Rietpoort Residential Development, Westonaria South Housing Development, Doornkuil Residential Development, Fleurhof Residential Development, Klapmuts Residential Development, Celebration Northriding and Perle de Fleuve residential development.
- Mines including Klipfontein Mine, New Largo Coal Mine, Sishen Mine: Western Waste Rock Dumps, Sishen Complex Mining Right Application,

Sishen Mine: expansion of Lylyveld South Pit, Smokey Hills Mine, Kalplats Mine, Burnstone Mine, Rössing Uranium, Kitumba Copper Mine, Wallmansthal Fluor mine, Zandkopsdrift mine, Leidon mine, Paardeplaats mine, Aquilla mine and Kalahari mine.

- Waste sites such as Kendal Ash Disposal Facility, Camden Ash Dump, Biotshepi Landfill and Eskom Landfill Lephalale.
- Power generation projects including Khanyisa Power Station, Coal 3 and 4 Power Stations, Vaal South power station and Waterberg power stations.
- Roads include the Strategic Socio-economic analysis N2/R72, upgrade of the K46 and Bushbuck Ridge bypass road.
- Terrain suitability study Palabora Mining Company.
- Recreational facilities such as Westridge Mall, West Rand Casino, Viking Bay and Rustenburg Mall.
- Lebone II College of the Royal Bafokeng.
- Shallcross, Stanger and Komatipoort Filling Stations.
- Social and Labour Plans such as Kalplats Mine, Kalahari Mine, Highveld Crushers.
- Social aspects of Social & Environmental Management System: Kelvin Power.
- Integrated Management Plan: Vredefort Dome World Heritage Site.
- Karoo Array Telescope.
- Coastal Livelihood Assessment Paternoster & Melkhoutfontein.
- Powerlines including Garona/Aries, De Beers/Eskom Voorspoed Mine, Mamelodi /Hatherley transmission lines, Soweto Integration Power Lines, Eskom /Tabor-Spencer, Eskom Kudu, Solar Park Integration Project, Eskom Camden-Theta Transmission lines and KZN Integration Project.
- Golf Estates including Lizard Point, The Ponds, Huddle Park, Royal Maluti and Northern Golf Courses.
- Township developments for Putfontein, Klipfontein, Vlakfontein, Duduza, Chief Alfred Luthuli, Rooikop Station, Payneville, Etwatwa and Mayfield, amongst others.

Closure planning

- Assessment of the local socio-economic impacts of the closure of Exxaro's Zincor plant near Springs, Gauteng
- Stakeholder Engagement Strategy for Social Mine Closure: Husab Mine, Erongo Region, Namibia

Social Audits/Due diligence 2001-

- Kelvin Power
- EnviroServ
- Shoprite Angola

Gender Analysis 2018-

- Lesotho Lowlands Bulk Water Supply Scheme (Zone 2&3)
- Human Rights Impact of Grave Relocation Mogalakwena Mine

Human Rights Analysis 2020-	• Human Rights Due Diligence ANRML Nigeria
Social Management Implementation: 2009 –	• Mokolo Crocodile Water Augmentation Project • Upgrade of Staff infrastructure in Etosha National Park (2012-2014)
Policy development 2015-	• Developed Stakeholder Engagement Policies, Plans and Procedures for Calgro M3 • Developed a Social Impact Assessment Policy for the Seychelles • Assessment of the impact of modernisation of mining on mine-affected communities as part of the the Research Programme on Successful Application of Technology Centred Around People (SATCAP) • Mineral Sector Support for Economic Diversification (MinDiver) Project, Nigeria – Project advisor: Development of Social Accountability framework, and Integration of Social Accountability Activities along the Mining Industry Value Chain and Project Life Cycle
Stakeholder Engagement 2001 –	• Stakeholder engagement lead: Mpofu Wind Farms • Facilitation of DWA National Estuarine Monitoring Programme workshop • Public participation on numerous small projects, e.g. Naschem Explosives Factory, Witwatersrand Gold Refinery, Middleburg Ferrochrome, Watervalboven Chemicals • Establishment of a Water Users association – Grootegeluk mine • Grootegeluk Coal Mine • Stuart Coal Colliery • Gauteng Government Precinct • Thabeng Eco reserve and Golf Estate • Mogol Club, Lephalale • Leeuwpan Environmental education centre • Ponds Golf Estate • Manzengwenya Dive Camp, St Lucia • Kalahari Mine • Huddle Park Golf Estate • De Beers/Eskom Voorspoed Mine power line • Eskom Tabor-Spencer power line • Colombus Stainless • Lebone II College of the Royal Bafokeng
Training 2001-	• Presented training on the implementation of voluntary principles on security and human rights to Calgro M3 • Presented and facilitated course on social entrepreneurship in partnership with the University of Pretoria, Unisa, SAVF and Future Families

- Facilitated, developed and coordinated the Population, Environment and Development (PED) Nexus course for the international non-government organisation Leaders in Environment and Development (LEAD), the United Nations Population Fund and the Department of Social Development
- Presenting module on Social Impact Assessment and Public Participation to Masters' Degree Students in environmental management at the University of the Orange Free State
- Presenting module on Social Impact Assessment and Public Participation to honours' degree students in environmental management at the University of South Africa
- Presenting module on Social Impact Assessment to final year students in environmental management at the Tshwane University of Technology
- Presenting module on Social/Community Issues in Risk Assessment for the Environmental Risk Assessment course at the Centre for Environmental Management at the University of the Northwest
- Presenting training courses in Environmental Management topics and Social Impact Assessment at the Centre for Environmental Management at the University of the Northwest
- Presenting training in Social Impact Assessment to Masters' Degree students in the Department of Geography and Environmental Sciences at University of the Northwest
- Presenting training in Social Impact Assessment to final year engineering students in the Department of Engineering at University of Pretoria
- Presenting training in Social Impact Assessment to Masters' Degree students in the Department of Social Work at University of Pretoria
- Assisted with developing and presenting the Masters' Degree in Social Impact Assessment at the Department of Sociology, University of Johannesburg and presented modules
- Presenting training in Social Impact Assessment and Environmental Impact Assessment for the NGO Leaders in Environment and Development and the Department of Social Development
- Drafted Guidelines for Socio-economic Impact Assessment for the Integrated Environmental Management Series Guidelines, Department of Environmental Affairs and Tourism
- Present SIA course at the Centre for Environmental Management.
- Present SIA course at Eskom.

Human behaviour studies 2009 -

- Human behaviour studies in gold mining areas as input for modelling for radiological impact assessment studies (Clients include Harmony, Anglo Gold Ashanti, Bosveld Phosphates, Tronox and others)

San-Marié Aucamp
Research Psychologist

Summary	San-Marié is the founding member of Equispectives Research and Consulting Services with over 25 years' experience working in the social environment, predominantly in the mining sector. Experience in other sectors include energy, manufacturing, government, automotive, financial services, telecoms and IT, and FMCG. She has experience in compiling and reviewing Social and Labour Plans, conducting Social Impact Assessments and developing customised social monitoring and evaluation tools for clients.
Qualifications	Currently busy with PhD in Consulting Psychology at the University of South Africa MA (Research Psychology), University of Pretoria, 2003 University of Pretoria, Not for degree purposes – Mathematical Statistics 1 (while working full-time), 1996 University of South Africa, Not for degree purposes – Mathematics 3 & Computer Science 1 (while working full-time), 1994 Higher Education Diploma (Post graduate), University of Pretoria, 1992 BA (Hons) Psychology, University of Pretoria, 1991 BA (cum laude), University of Pretoria (majored in Psychology and Criminology), 1990
Registration(s)	Health Professions Council of South Africa – Research Psychologist and Psychometrist in independent practice
Affiliations	Psychological Society of South Africa – member Society for Industrial and Occupational Psychology of South Africa – member Services SETA – Past National Council Member
Countries of work experience	South Africa, Zambia, Botswana; Lesotho, Ghana, Kenya, Namibia, Hong Kong, Seychelles, Tanzania Managed multi-country projects (from South Africa) with fieldwork in Swaziland; Uganda; Rwanda; Nigeria; Cameroon; Namibia, Hungary, Japan, China, India
Nationality	South African
Years of experience	27

PROFESSIONAL EXPERIENCE

Social Impact Assessments & Social and Labour Plans **2007 –**	Design, execution and project management of SIA's, SLP's and social research input as part of multi-disciplinary projects Conducting baseline studies for SIA's using social indicators such as poverty rate, unemployment rate, crime, literacy levels, income, household size, access to water, etc. Reporting, data analysis and client liaison Review SLP's

Human behaviour studies 2009 -	Human behaviour studies in gold mining areas as input for modelling for radiological impact assessment studies
Social & marketing research 1997 –	Translating client needs in research projects – including measurement, tracking, monitoring and evaluation Design, implementation and project management of research projects (qualitative and quantitative methodologies, including statistics and indices) Reporting, analysis and client liaison Worked on more than 100 research projects Project size varies from about 10 to 3 500 respondents Project respondents varied in age, gender, cultural group and educational level Project types include employee satisfaction, customer satisfaction, product tests, branding, etc. Industry experience and clients include the mining, manufacturing, agriculture, government, automotive, financial services, telecoms and IT as well as FMCG sectors Worked on multi country projects as either team member or team leader
Training 1997 -	Research methodology for second year psychology students (1998) Guest lecturer in modules on Social Impact Assessment, Public Participation and Social and Labour Plans at UNISA, Tshwane University of Technology, University of Johannesburg, Centre for Environmental Management (North West University) Public meeting facilitation skills – SAPREF (2010) Social Impact Assessment Training – Seychelles (2017)
Social Life Cycle Assessment 2013 -	Develop data collection tool Data collection, interpretation and reporting of results Social life cycle assessment reporting Develop reference criteria/benchmarks to track social performance Audit/measure industry/client against benchmarks

DECLARATION OF THE ENVIRONMENTAL SPECIALIST

I, Ilse Carin Aucamp, declare that –

General declaration:

- I act as an independent specialist in this application.
- I will perform the work relating to the application in an objective manner, even if this results in views and findings that are not favorable to the applicant.
- I declare that there are no circumstances that may compromise my objectivity in performing such work.
- I have expertise in conducting undertaking the specialist work as required, including knowledge of the Act, Regulations and any guidelines that have relevance to the proposed activity.
- I will comply with the Act, Regulations, and all other applicable legislation.
- I have not, and will not engage in, conflicting interest in the undertaking of the activity.
- I understand to disclose to the applicant and competent authority all material information in my possession that reasonably has or may have the potential of influencing- any decision to be taken with respect to the application by the competent authority; and the objectivity of any report, plan or document to be prepared by myself for submission to the competent authority.
- I have taken into account, to the extent possible, the matters referred to in Regulation 18 when preparing the report, plan or document.
- I will provide the competent authority with access to all information at my disposal regarding the application, whether such information is favorable to the applicant or not.
- All the particulars furnished by me this form are true and correct.
- I will perform all other obligations as expected from an environmental assessment practitioner in terms of the Regulations.
- I am aware of what constitutes an offence in terms of Regulation 48 and that a person convicted of an offence in terms of Regulation 48(1) is liable to the penalties as contemplated in Section 49B of the Act.

Disclosure of Vested Interest

I do not have and will not have any vested interest (either business, financial, personal or other) in the proposed activity proceeding other than remunerative for work performed in terms of the Regulations.

Signature of the Specialist:

Name of Company: Equispectives Research & Consulting Services

Date: 28/11/2022

UNDERTAKING UNDER OATH/AFFIRMATION

I, Ilse Carin Aucamp, swear under oath/affirm that all the information submitted or to be submitted for the purposes of this application is true and correct.

Executive Summary

Environmental Impact Management Services Pty Ltd. (EIMS) is proposing to undertake a 3D seismic survey within the Orange Basin off the West and South-West Coast of South Africa. The proposed survey areas are adjacent to a few Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs) including Childs Bank and Shelf Edge, and Cape Canyon and Associated Islands, Bays and Lagoon.

SLR Consulting Australia Pty Ltd. (SLR) has been appointed by EIMS as the independent underwater acoustic specialist to undertake a Sound Transmission Loss Modelling (STLM) study for the proposed exploration activities, in order to assist with the assessment of potential noise impact on marine fauna species of interest.

The noise modelling results have been used to identify zones of impact for marine mammals and other species of concern based on relevant noise impact assessment criteria. Zones of impact have been evaluated for physiological effects and behavioural disturbance, due to the immediate impact from single airgun pulses, as well as the cumulative effects of exposure to multiple airgun pulses over a period of 24 hours.

The noise impact assessment criteria for the marine fauna species of concerns are detailed in Section 2.0 of this report, and the identified relevant zones of impact are summarised in Section 5.4 and Section 5.5 of the report. The identified relevant zones of impact for marine mammals, fish and sea turtle species are summarised as follows:

Marine mammals

Impact from immediate exposure to individual airgun array pulses

Due to the high level of impulsive signal emissions from the array source, marine mammals are predicted to experience a permanent auditory threshold shift (PTS) at close proximity to the source arrays due to the immediate exposure to individual pulses. Marine mammals of all hearing groups except very-high-frequency cetaceans are predicted to experience PTS effect within approximately 50 metres from the 3D source array at all assessed water depth scenarios. The maximum zones of PTS effect for very-high-frequency cetaceans are predicted to be within 325 metres from the 3D array source.

The zones of a temporary auditory threshold shift (TTS) due to a single pulse exposure for marine mammals of all hearing groups except very-high-frequency cetaceans are predicted to be within approximately 100 m from the source array. The maximum zones of TTS effect for very-high-frequency cetaceans are predicted to be within 650 m from the array source.

Behavioural disturbance caused by the immediate exposure to individual pulses are predicted to be within 3.8 km from the array source for marine mammals of all hearing groups.

Impact from cumulative exposure to multiple airgun array pulses

The zones of cumulative impact (i.e., the maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels) are estimated based on the modelling results and relevant assessment criteria. Among marine mammals of all six hearing groups, low-frequency cetaceans have the highest zones of PTS and TTS impact. The zones of PTS impact are predicted to range up to 340 metres for the 3D survey, from the adjacent survey lines for the relevant typical 24-hour survey operation

SLR

5028

scenarios considered, and the maximum zone of TTS impact is predicted to be around 5 km from the adjacent survey lines. Much lower zones of cumulative PTS and TTS impact are predicted for marine mammals of other hearing groups.

Fish

Impact from immediate exposure to individual airgun array pulses

The zones of potential injuries for fish species with a swim bladder, turtles and fish eggs and fish larvae are predicted to be within 180 m from the array source. However, fish species without swim bladders have higher injury impact thresholds, and therefore have smaller zones of potential injuries within 90 m from the airgun array source.

Impact from cumulative exposure to multiple airgun array pulses

The zones of potential mortal injuries for fish species with a swim bladder, fish eggs, and fish larvae are predicted to be within 30 m from the adjacent survey lines for all the 24-hour survey operation scenarios considered. For recoverable injury, the zones of impact are predicted to be within 80 m from the adjacent survey lines for fish with a swim bladder for all the operation scenarios considered. Fish without swim bladder are not expected to suffer or any potential injury.

The zones of TTS effect for fish species with and without swim bladders are predicted to be within 2.9 km from the adjacent survey lines for the relevant 24-hour survey operation scenarios considered.

Existing experimental data regarding recoverable injury and TTS impacts for fish eggs and larvae is sparse and no guideline recommendations have been provided. However, based on a subjective approach, noise impacts are expected to be moderate for fish eggs and larvae. Impact is expected to be low for all of them at intermediate and far field from the source location.

Sea Turtles

Impact from immediate exposure to individual airgun array pulses

The maximum zones of PTS effect for sea turtles are predicted to be within 19 m from the source location. On the other hand, the maximum zones of TTS effect for sea turtles are predicted to be within 24 m of the source array.

The behavioural disturbance for sea turtles caused by the immediate exposure to individual pulses are predicted to be within 1.3 km of the source array.

Impact from cumulative exposure to multiple airgun array pulses

Noise impacts related to recoverable injury and TTS on sea turtles are expected to be high at the near field from the source location. The maximum zones of PTS impact are predicted to range within 10 m of the source array. The maximum zones of TTS effect for sea turtles are predicted to be within 500 m of the source array.

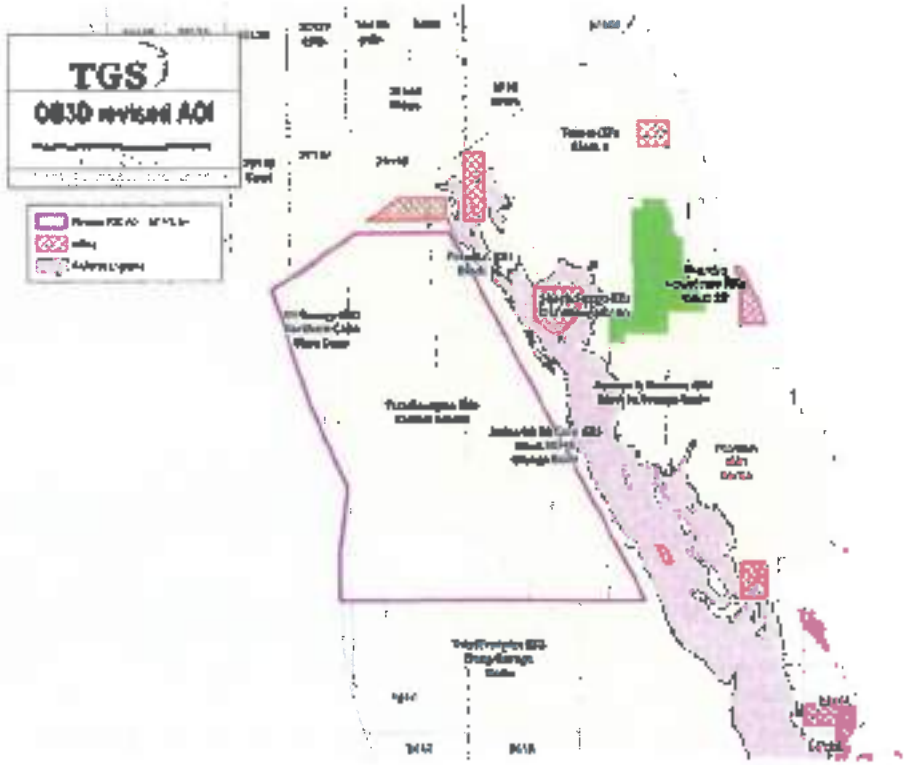
1.0 Introduction

1.1 Project Background

TGS is proposing to undertake a 3D seismic survey within the Orange Basin off the West Coast of South Africa. Water depths in the proposed survey area range from 1,500 m to beyond 3,600 m. The proposed 3D survey acquisition area is within the entire Reconnaissance area of approximately 30,000 km^2 as shown in Figure 1.

Figure 1 Proposed 3D Seismic Survey area off the West Coast of South Africa (purple polygon)



There are a few Ecologically or Biologically Significant Marine Areas (EBSAs) and Marine Protected Areas (MPAs)[1] adjacent to the proposed survey area, particularly the Child Bank and Shelf Edge, as well as Cape Canyon and Associated Islands, Bays and Lagoon, as shown in Figure 2 below:

- Childs Bank and Shelf Edge (Childs Bank) which is a unique submarine bank feature occurring within South Africa's Exclusive Economic Zone (EEZ), rising from ~180 m to ~400 m in water depth on the western continental margin on South Africa; This area includes seven ecosystem types, including those comprising the bank itself, the outer shelf and the shelf edge, supporting hard and unconsolidated ecosystem types. Two of these ecosystem types are Vulnerable and five are Least Concern.

[1] https://www.mandela.ac.za/Research-Projects/EBSA-Portal/South-Africa accessed on May 20th, 2021.

- **Cape Canyon and Associated Islands, Bays and Lagoon** which comprises a collection of special features, ecosystems and species that support a rich diversity and high productivity. The area supports numerous threatened species and ecosystems, and many fragile, sensitive species.

Figure 2 **EBSA boundaries (black polygons) for 'Childs Bank and Shelf Edge' (left) and 'Cape Canyon and Associated Islands, Bays and Lagoon' (right). Dark blue areas represent Marine Protected Areas (MPAs).**

SLR Consulting Australia Pty Ltd. (SLR) has been appointed by Environmental Impact Management Services Pty Ltd (EIMS) as the independent underwater acoustic specialist to undertake a Sound Transmission Loss Modelling (STLM) study for the proposed exploration activities, in order to assist with the assessment of potential noise impact on marine fauna species of interest, particularly for these major marine sensitive areas of concern detailed as above.

1.2 Structure of the Report

This modelling study for the proposed 3D seismic surveys within the Orange Basin off the west coast of South Africa includes the following modelling components:

- Airgun source modelling, i.e., modelling of sound energy emissions from the source array proposed to be used in the 3D seismic survey, including the far-field signature and its power spectral density (PSD), as well as the beam pattern of the source array.
- Short range modelling, i.e., prediction of the received noise levels over a range of up to four kilometres from the selected array source location of various depths, in order to investigate sound field variations due to the water depth changes, as well as to assess the potential high-risk immediate noise impact to marine fauna species of interest.
- Long range modelling, i.e., prediction of the received noise levels over a range of up to two hundred kilometres from the selected array source locations, in order to assess the potential noise impact from the surveys on relevant far-field marine sensitive areas.
- Cumulative noise exposure modelling, i.e., prediction of the cumulative SELs over a 24-hour period for selected representative survey scenarios adjacent to marine sensitive areas, to assess the potential cumulative noise impact to marine fauna species of interest.

SLR

Section 1.0 of the report provides relevant noise impact assessment criteria for marine fauna species of interest. Section 3.0 details the modelling methodology, procedure and results for the seismic survey array source modelling. Section 4.0 outlines the methodologies and procedures for the seismic survey acoustic modelling components (including short range and long-range transmission loss modelling and the cumulative noise exposure modelling). Section 0 presents the major modelling results and the estimated zones of impact for marine fauna species of interest. Section 6.0 provides a discussion of the acoustic modelling study and some recommendation management measures. Relevant references cited throughout the report are listed in Section 9.0.

Relevant acoustic terminologies used throughout the report are presented in Appendix A. An explanation of marine mammal and sea turtle auditory weighting functions are presented in Appendix B. Classifications of various marine mammal hearing groups are presented in Appendix C. Supplementary noise modelling figures are presented in Appendix D.

SLR

5/23

2.0 Underwater Noise Impact Assessment Criteria

2.1 Impact of Noise on Marine Fauna Species

The effects of noise and the range over which these effects take place depend on the acoustic characteristics of the noise (e.g., source level, spectral content, temporal characteristics[2], directionality, etc.), the sound propagation environment as well as the hearing ability and physical reaction of individual marine fauna species. The potential impacts of noise on marine fauna species include audibility/detection, masking of communication and other biological important sounds, behavioural responses and physiological impacts which generally include discomfort, hearing loss, physical injury, and mortality (Richardson et al. 2013; Erbe et al. 2018; Popper and Hawkins 2019a).

When the animal is in close proximity to the acoustic source, physical injuries can occur. As the animal is further away from the source, the impacts are expected to gradually decrease, up to a distance where the impacts are negligible. The theoretical zones of noise influence according to Richardson et al. (2013) based on the severity of the noise impact are illustrated in Figure 3.

Figure 3 Theoretical zones of noise influence (adapted from Richardson et al. 2013)

2.1.1 Audibility

A sound is audible when the receiver is able to perceive it over background noise. The audibility is also determined by the threshold of hearing that varies with frequency. The frequency dependant hearing sensitivity is expressed in the form of a hearing curve (i.e., audiogram). In general, marine mammals and fish species usually have U-shaped audiograms, meaning that within their respective hearing ranges, they are more sensitive to the sound energy component in the mid frequency range, and less sensitive to the

[2] Impulsive noise is typically very short (with seconds) and intermittent with rapid rise and decay back to ambient levels (e.g., noise from pile driving, seismic airguns and seabed survey sonar signals).

SLR

5028

energy components in the lower and upper frequency ranges (Finneran 2016, Southall et al. 2019; Popper et al. 2019b).

For fish species, their sound detection is based on the response of the auditory portion of their ears (i.e., the otolithic organs) to particle motion of the surrounding fluid (Popper and Hawkins 2018). Some fish species have the ability to detect sound pressure via gas-filled structures near the ear and/or extensions of the swim bladder that functionally affect the ear, in addition to purely the fluid particle motion, which as a result increase hearing sensitivity and broaden the hearing bandwidth (Nedelec et al. 2016; Popper and Hawkins 2018).

2.1.2 Masking

Masking occurs when the noise is high enough to impair detection of biologically relevant sound signals such as communication signals, echolocation clicks and passive detection cues that are used for navigation and finding prey. The zone of masking is defined by the range at which sound levels from the noise source are received above threshold within the 'critical band'[3] centred on the signal (Richardson et al. 2013), and therefore strongly dependent on background noise environment.

The potential for masking can be reduced due to an animal's frequency and temporal discrimination ability, directional hearing, co-modulation masking release (if noise is amplitude modulated over a number of frequency bands) and multiple looks (if the noise has gaps or the signal is repetitive), as well as anti-masking strategies (increasing call level, shifting frequency, repetition, etc.) (Erbe 2016).

2.1.3 Response

Responses to noise include changes in vocalisation, resting, diving and breathing patterns, changes in mother-infant relationships, and avoidance of the noise sources. For behavioural responses to occur, a sound would mostly have to be significantly above ambient levels and the animal's audiogram.

The behavioural response effects can be very difficult to measure and depend on a wide variety of factors such as the physical characteristics of the signal, the behavioural and motivational state of the receiver, its age, sex and social status and many others. Therefore, the extent of behavioural disturbance for any given signal can vary both within a population as well as within the same individual. Behavioural reactions can vary significantly, ranging from very subtle changes in behaviour to strong avoidance reactions (Ellison et al. 2012; Richardson et al. 2013).

2.1.4 Hearing Loss / Discomfort

Physiological effects of underwater noise are primarily associated with the auditory system which is likely to be most sensitive to noise. The exposure of the auditory system to a high level of noise for a specific duration can cause a reduction in the animal's hearing sensitivity, or an increase in hearing threshold (Finneran 2016, Popper and Hawkins 2019a; Southall et al. 2019).

If the noise exposure is below some critical sound energy level, the hearing loss is generally only temporary, and this effect is called temporary hearing threshold shift (TTS). If the noise exposure exceeds the critical sound energy level, the hearing loss can be permanent, and this effect is called permanent hearing threshold shift (PTS).

[3] In biological hearing systems, noise is integrated over several frequency filters, called the critical bands.

SLR

2022

2.1.5 Physical Injury

In a broader sense, physiological impacts also include non-auditory physiological effects. Other physiological systems of marine animals potentially affected by noise include the vestibular system, reproductive system, nervous system, liver or organs with high levels of dissolved gas concentrations and gas filled spaces. Noise at high levels may cause concussive effects, physical damage to tissues and organs, cavitation or result in rapid formation of bubbles in venous system due to massive oscillations of pressure (Groton 1998).

From an adverse impact assessment perspective, among the potential noise impacts above, physiological impacts are deemed as the primary adverse impact, and behavioural responses as the secondary adverse impact. The following sub-sections outline the corresponding impact assessment criteria for marine mammals and fish and sea turtle species, as well as human divers and swimmers, based on a review of relevant guidelines and/or literature published.

2.2 Marine Mammals, Fish and Sea Turtles

There have been extensive scientific studies and research efforts to develop quantitative links between marine noise and impacts on marine mammal species, fish, and sea turtles. For example, Southall et al (2019) have proposed noise exposure criteria associated with various sound types, including impulsive noise (e.g., piling noise and seismic airgun noise) and non-impulsive noise (e.g., vessel and drilling noise)) for certain marine mammal species (i.e., cetaceans, sirenians and carnivores), based on review of expanding literature on marine mammal hearing and on physiological and behavioural responses to anthropogenic sounds. Popper *et al.* (2014) proposed sound exposure guidelines for fishes considering the diversity of fish, the different ways they detect sound, as well as various sound sources and their acoustic characteristics. Finneran et al (2017) presented a revision of the thresholds for sea turtle injury and hearing impairment (TTS and PTS).

The following subsection provides the noise exposure levels above which adverse effects on various groups of marine mammals, fish, and sea turtles. The latter is based on all available relevant data and published literature (i.e., the state of current knowledge). For more details, see Appendix B.

2.2.1 Noise Impact Criteria for Marine Mammals

The newly updated scientific recommendations in marine mammal noise exposure criteria (Southall et al, 2019) propose PTS-onset and TTS-onset criteria for impulsive noise events.

- The PTS-onset and TTS-onset criteria for impulsive noise are outlined in Table 1, which incorporate a dual-criteria approach based on both peak sound pressure level (SPL) and cumulative sound exposure level (SEL) within a 24-hour period (SEL_{24h}).
- For behavioural changes, the widely used assessment criterion for the onset of possible behavioural disruption in marine mammals is root-mean-square (RMS) SPL of 160 dB re 1 µPa for impulsive noise, as shown in Table 2.

SLR

1503

Table 1 PTS and TTS threshold levels for individual marine mammals exposed to impulsive noise events (Southall et al. 2019)

Marine mammal hearing group	PTS and TTS threshold levels – impulsive noise events			
	Injury (PTS) onset		TTS onset	
	Pk SPL, dB re 1µPa	Weighted SEL_{24h}, dB re 1µPa²·S	Pk SPL, dB re 1µPa	Weighted SEL_{24h}, dB re 1µPa²·S
Low-frequency cetaceans (LF)	219	183	213	168
High-frequency cetaceans (HF)	230	185	224	170

Phocid carnivores in water (PCW)	218	185	212	170
Other marine carnivores in water (OCW)	232	203	226	188

Table 2 The behavioural disruption threshold level for individual marine mammals – impulsive noise (NOAA 2019)

Marine mammal hearing group	Behavioural disruption threshold levels, RMS SPL, dB re 1µPa
	Impulsive noise
All hearing groups	160

2.2.2 Noise Criteria for Fish, Fish Eggs, and Fish Larvae

In general, limited scientific data are available regarding the effects of sound for fishes. As such, assessment procedures and subsequent regulatory and mitigation measures are often severely limited in their relevance and efficacy. To reduce regulatory uncertainty for all stakeholders by replacing precaution with scientific facts, the U.S. National Oceanic and Atmospheric Administration (NOAA) convened an international panel of experts to develop noise exposure criteria for fishes and sea turtles in 2004, primarily based on published scientific data in the peer-reviewed literature. The panel was organized as a Working Group (WG) under the ANSI-Accredited Standards Committee S3/SC 1, Animal Bioacoustics, which is sponsored by the Acoustical Society of America.

The outcomes of the WG are broadly applicable sound exposure guidelines for fish, fish eggs and fish larvae (Popper et al 2014), considering the diversity of fish and the different ways they detect sound, as well as various sound sources and their acoustic characteristics. The sound exposure criteria for sound sources relevant to the project including impulsive noise from seismic airguns is presented in Table 3.

Within the two tables, where data exist that can be used to suggest provisional guidelines, received signal levels are reported in appropriate forms (e.g., peak SPL, SEL). Where insufficient data exist to make a recommendation for guidelines, a subjective approach is adopted in which the relative risk of an effect is placed in order of rank at three distances from the source – near (N), intermediate (I), and far (F) (top to bottom within each cell of the table, respectively). In general, "near" might be considered to be in the tens of meters from the source, "intermediate" in the hundreds of meters, and "far" in the thousands of meters. The relative risk of an effect is then rated as being "high," "moderate," and "low" with respect to

SLR

source distance and animal type. The rating for effects in these tables is highly subjective and represents general consensus within the WG.

It should be noted that the period over which the cumulative sound exposure level (SEL_{cum}) is calculated must be carefully specified. For example, SEL_{cum} may be defined over a standard period (e.g., 12 hours of seismic survey or for the duration of an activity), or over the total period that the animal will be exposed. Whether an animal would be exposed to a full period of sound activity will depend on its behaviour, as well as the source movements. To be in line with assessment criteria for marine mammals, an exposure period of 24 hours is specified for fish. The receiving exposure levels over this period are expected to reflect the total exposure at near field where the major adverse impacts are expected to occur for fish species.

Table 3 Noise exposure criteria for seismic airguns – fish, fish eggs and fish larvae (Popper et al. 2014)

Type of animal	Mortality and potential mortal injury	Impairment			Behaviour
		Recovery injury	TTS	Masking	
Fish: no swim bladder (particle motion detection)	>219 dB SEL_{cum} or >213 dB Pk SPL	>216 dB SEL_{cum} or >213 dB Pk SPL	>>186 dB SEL_{cum}	(N) Moderate (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder is not involved in hearing (particle motion detection)	210 dB SEL_{cum} or >207 dB Pk SPL	203 dB SEL_{cum} or >207 dB Pk SPL	>>186 dB SEL_{cum}	(N) Moderate (I) Low (F) Low	(N) High (I) Moderate (F) Low
Fish: swim bladder involved in hearing (primarily pressure detection)	207 dB SEL_{cum} or >207 dB Pk SPL	203 dB SEL_{cum} or >207 dB Pk SPL	186 dB SEL_{cum}	(N) High (I) High (F) Moderate	(N) High (I) High (F) Moderate
Fish eggs and fish larvae	>210 dB SEL_{cum} or >207 dB Pk SPL	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low	(N) Moderate (I) Low (F) Low

Notes: Peak sound pressure levels (Pk SPL) dB re 1 µPa; Cumulative sound exposure level (SEL_{cum}) dB re 1 μPa^2-s. All criteria are presented as sound pressure even for fish without swim bladders since no data for particle motion exist. Relative risk (high, moderate, low) is given for animals at three distances from the source defined in relative terms as near (N), intermediate (I), and far (F).

2.2.3 Noise Criteria for Sea Turtles

Popper et al. (2014) suggested threshold levels for the occurrence of mortality and potential mortal injuries (PTS) of sea turtles. However, these adopted levels were extrapolated from other animal groups such as fish, based on the logic that the hearing range of turtles is much closer to that of poorly hearing fish.

More recently, Finneran et al (2017) revised the sea turtle thresholds (PTS) by reviewing individual references from at least five different species (see Appendix C) to construct their composite audiograms and provide thresholds for onset of temporary hearing impairment (TTS). Finneran et al (2017) agreed that sea turtles, even within their best hearing range, have low sensitivity with audiograms more similar

to those of fish without specialized hearing adaptations for high frequency like some marine mammals. The revised thresholds for sea turtles are presented in Table 4.

Table 4 PTS and TTS threshold levels for sea turtles exposed to impulsive noise events (Finneran et al. 2017)

Type of animal	PTS and TTS threshold levels – impulsive noise events			
	Injury (PTS) onset		TTS onset	
	Pk SPL, dB re 1µPa	Weighted SEL_{24hr}, dB re $1\mu Pa^2 \cdot S$	Pk SPL, dB re 1µPa	Weighted SEL_{24hr}, dB re $1\mu Pa^2 \cdot S$
Sea turtles	232	204	226	189

The behavioural threshold for sea turtles was initially established by McCauley *et al.* (2000) at 166 dB re 1 µPa SPL rms and then it was adopted by the National Marine Fisheries Services (NMFS) to identify the distances at which behavioural response may occur. However, the received sound level at which sea turtles are expected to actively avoid repeated air gun exposures is 175 dB re 1 µPa SPL rms (McCauley et al. 2000) as shown in Table 5. Therefore, this threshold has been applied by NMFS to estimate sea turtle behaviour reactions to repeated air gun activities such as survey seismic events (Finneran et al. 2017).

Table 5 The behavioural threshold level for sea turtles – air guns events (McCauley et al. 2000; Finneran et al. 2017)

Type of animal	Behavioural disturbance threshold levels – air guns events
	RMS SPL, dB re 1µPa
Sea turtles	175

2.3 Zones of Bioacoustics Impact

Received noise levels can be predicted using known source levels in combination with models of sound propagation transmission loss between the source and the receiver locations. Zones of impact can then be determined by comparison of the predicted received levels to the noise exposure criteria for the marine fauna species of concern.

It should be noted that the proposed noise exposure assessment criteria for impulsive noise events are all significantly higher than typical natural ambient noise levels, which have overall RMS SPLs in the range of 80 – 120 dB re 1 µPa in the case of calm to strong sea state conditions, respectively. Therefore, the natural ambient noise is not given consideration in the assessment of the zones of impact.

Predicted zones of impact define the environmental footprint of the noise generating activities and indicate the locations within which the activities may have an adverse impact on marine fauna species of interest, either behaviourally or physiologically. In this report, zones of impact are defined as follows:

- For immediate impact from single pulses – the zone of impact represents the maximum horizontal distance from the sound source; and
- For cumulative impact from a typical survey operation scenario – the zone of impact represents the maximum perpendicular horizontal distance from an active seismic survey line.

SLR

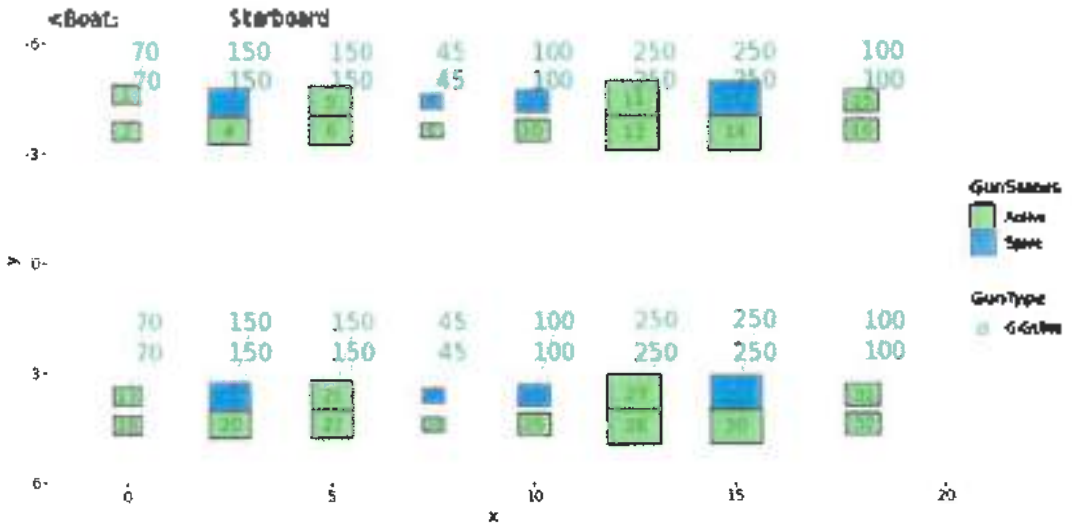
In all cases, zones of impact are conservatively determined by using the maximum predicted noise level across the water column to determine the zone of impact. Since noise levels vary with depth at any location, there will be areas in the water column within the identified zone of impact that are exposed to lower noise levels than implied by the identified zones of impact, which represent the worst case.

3.0 Seismic Airgun Array Source Modelling

3.1 Airgun Array Configuration

The seismic airgun array proposed is a 3 370 cubic inch (CUI) G-Gunll array (32 total airguns, 24 active) with its configuration shown in Figure 4 as below. The array consists of 24 active G-Gun airgun units and has an average towing depth of 7.0 m and an operating pressure of 2,000 pounds per square inch (psi).

Figure 4 The configuration of the 3 370 CUI G-Gunll array



3.2 Modelling Methodology

For each source array configuration, the outputs of the source modelling include:

- A set of "notional" signatures for each of the array elements; and
- The far-field signature of the array source, including its directivity/beam patterns.

3.2.1 Notional Signature

The notional signatures are the pressure waveforms of individual source elements at a standard reference distance of 1 metre.

Notional signatures are modelled using the Gundalf Designer software package (2018). The Gundalf source model is developed based on the fundamental physics of the oscillation and radiation of source bubbles as described by Ziolkowski (1970), and for an array source case, taking into account non-linear pressure interactions between source elements (Ziolkowski et al. 1982; Dragoset 1984; Parkes et al. 1984, Vaage et al 1984; Laws et al. 1988 & 1990).

The model solves a complex set of differential equations combining both heat transfer and dynamics and has been calibrated against multiple measurements of both non-interacting source elements and interacting clusters for all common source types at a wide range of deployment depths.

3.2.2 Far-field Signatures

The notional signatures from all airguns in the array are combined using appropriate phase delays in three dimensions to obtain the far-field source signature of the array. This procedure to combine the notional signatures to generate the far-field source signature is summarised as follows:

- The distances from each individual acoustic source to nominal far-field receiving location are calculated. A 9 km receiver set is used for the current study;
- The time delays between the individual acoustic sources and the receiving locations are calculated from these distances with reference to the speed of sound in water;
- The signal at each receiver location from each individual acoustic source is calculated with the appropriate time delay. These received signals are summed to obtain the overall array far-field signature for the direction of interest; and
- The far-field signature also accounts for ocean surface reflection effects by inclusion of the "surface ghost". An additional ghost source is added for each acoustic source element using a sea surface reflection coefficient of -1.

3.2.3 Beam Patterns

The beam patterns of the acoustic source array are obtained as follows:

a) The far-field signatures are calculated for all directions from the source using azimuthal and dip angle increments of 1-degree;

b) The power spectral density (PSD) (dB re 1 $\mu Pa^2s/Hz$ @ 1 m) for each pressure signature waveform is calculated using a Fourier transform technique; and

c) The PSDs of all resulting signature waveforms are combined to form the frequency-dependent beam pattern for the array.

3.3 Modelling Results

3.3.1 Notional Signatures

Figure 5 shows the notional source signatures for the four airgun array elements. Each line within the figure represents the notional source signature of the corresponding array element as shown in Figure 4.

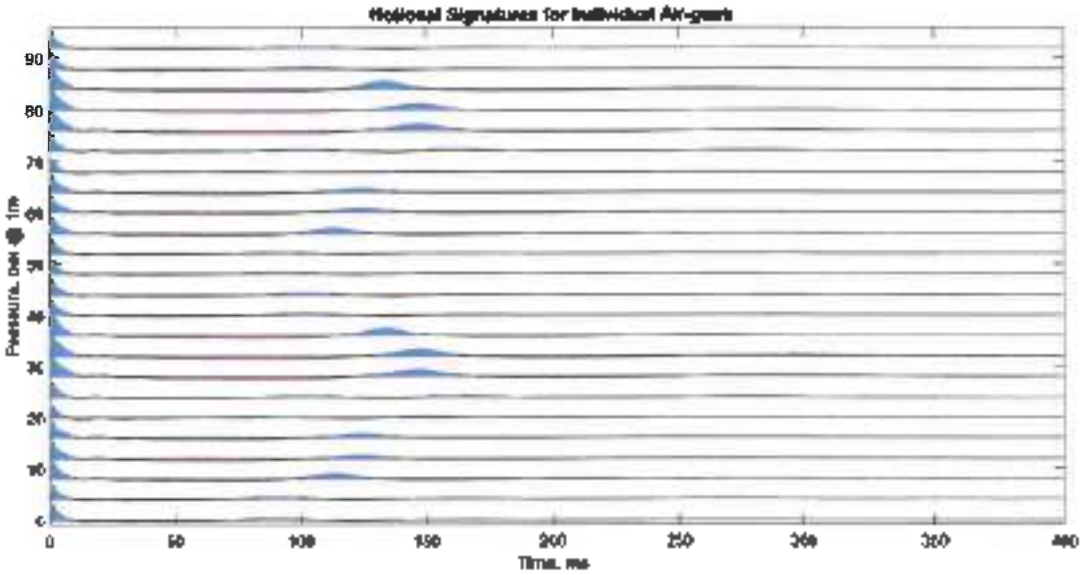
Figure 5 Notional source signatures for the 3 370 cui G-Gundi array



3.3.2 Far-field Signature and its Power Spectral Density

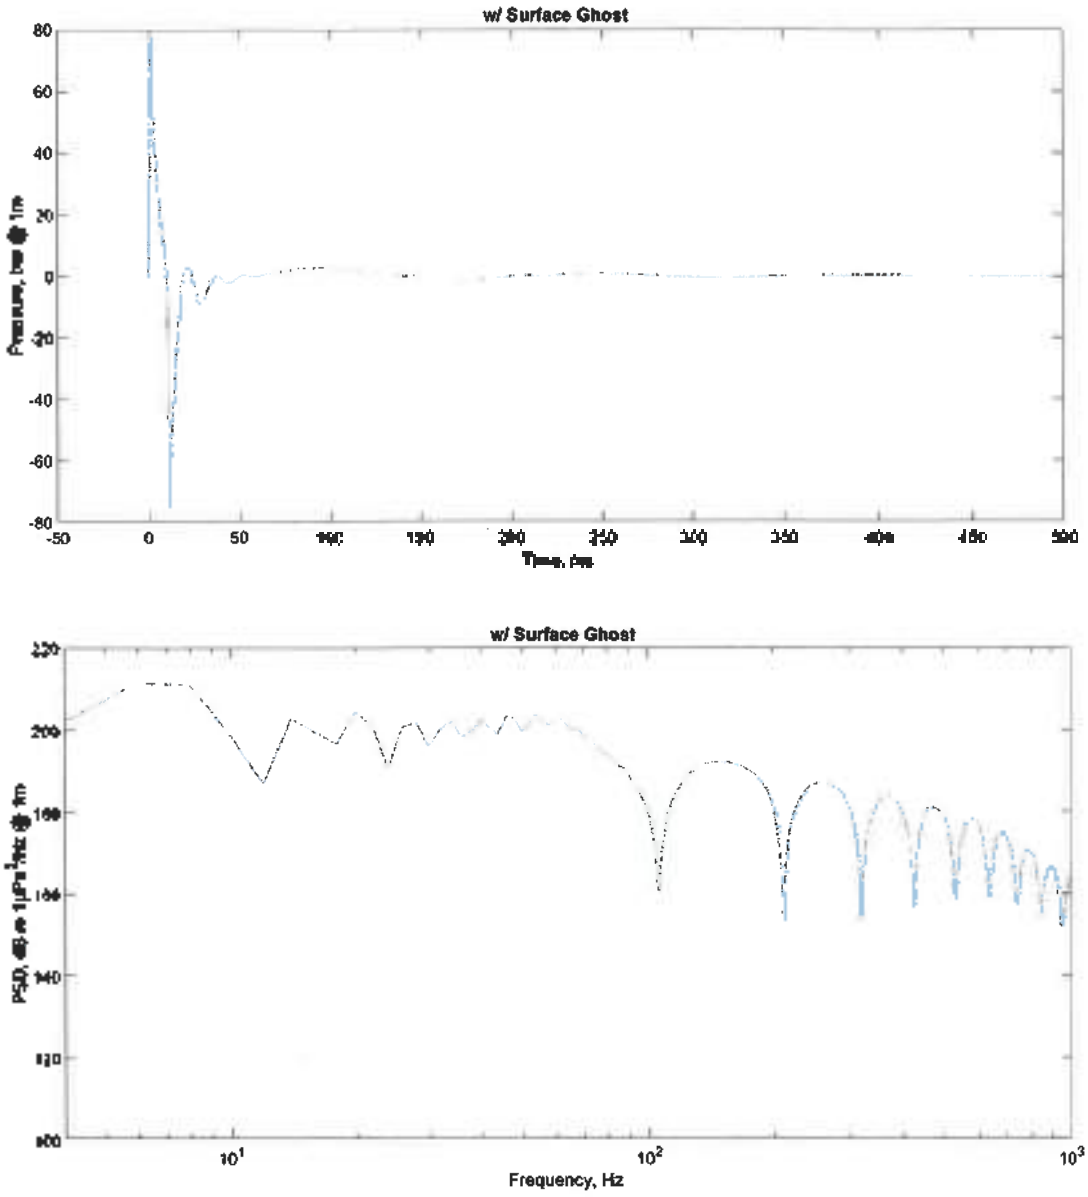
Figure 6 shows the far-field signature waveform and the proposed airgun array's power spectral density (simulated by the Gundalf Designer software, 2018). The signatures are for the vertically downward direction with surface ghost included. The source modelling result shows the parameters presented in Table 6.

Table 6 Source levels of the array source

Source Levels	3D source array
Peak sound pressure level (Pk SPL) (dB re 1 µPa @ 1 m)	257.9
Root-mean-square sound pressure level (RMS SPL) (dB re 1 µPa @ 1 m with a 90%-energy pulse duration of 12.5 milliseconds)	244.9
Sound exposure level (SEL) (dB re µPa^2-s @ 1 m)	233.9

SLR

Figure 6 The far-field signature in vertically downward direction (top) and its power spectral density (bottom) for the 3 370 CUI G-Gun array



3.3.3 Beam Patterns

Array far-field beam patterns of the following three cross sections are presented in Figure 7:

1. The horizontal plane (i.e., dip angle of 90 degrees) with azimuthal angle of 0 degree corresponding to the in-line direction;
2. The vertical plane for the in-line direction (i.e., azimuthal angle of 0 degree) with dip angle of 0 degree corresponding to the vertically downward direction; and
3. The vertical plane for the cross-line direction (i.e., azimuthal angle of 90 degrees) with dip angle of 0 degree corresponding to the vertically downward direction.

The beam patterns in Figure 7 illustrate strong angle and frequency dependence of the energy radiation from the array. The beam pattern of the horizontal plane shows relatively stronger energy radiation in the cross-line direction than in the in-line direction. The beam patterns of the in-line and cross-line vertical planes have the strongest radiation in the vertical direction.

Figure 7 **Array far-field beam patterns for the 3 570 CUI G-Gun II array, as a function of orientation and frequency. (a) - The horizontal plane with 0 degree corresponding to the in-line direction; (b) – The vertical plane for the in-line direction; (c) – The vertical plane for the crossline direction. The 0-degree dip angle corresponds to vertically downward direction**

4.0 Sound Transmission Loss Modelling

4.1 Modelling Input Parameters

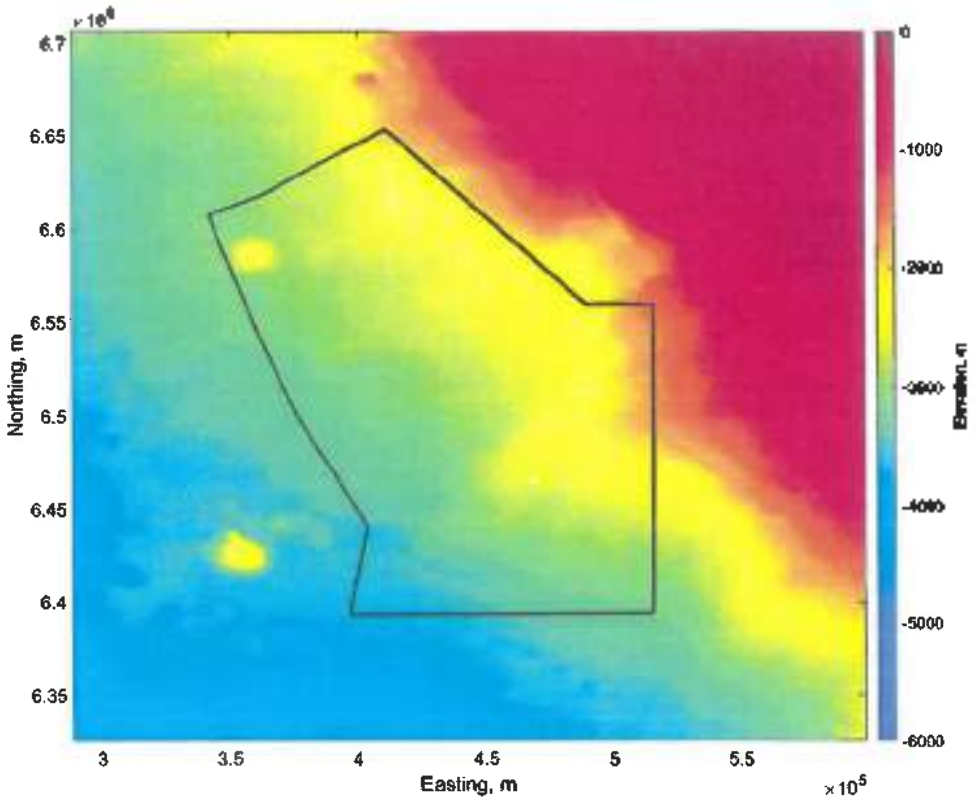
4.1.1 Bathymetry

The bathymetry data used for the sound propagation modelling were obtained from the General Bathymetric Chart of the Oceans (GEBCO) dataset grid (GEBCO 2022). This is the fourth GEBCO grid developed through the Nippon Foundation-GEBCO 'Seabed 2030 Project' (https://seabed2030.org).

The ocean currents within the survey area are not expected to have significant effects on sound propagation, due to limited current heights compared with overall water depths and low current speed compared with sound speed within typical sea water.

The bathymetric imagery within and surrounding the acquisitions area are presented in **Figure 8**.

Figure 8 **Bathymetry data for study area. The proposed 3D seismic area is shown with a black polygon, based on WGS 84/UTM Zone 33S**



4.1.2 Sound Speed Profiles

Temperature and salinity data required to derive the sound speed profiles were obtained from the World Ocean Atlas 2009 (WOA09) (Locarnini et al. 2010; Antonov et al. 2010). The hydrostatic pressure needed

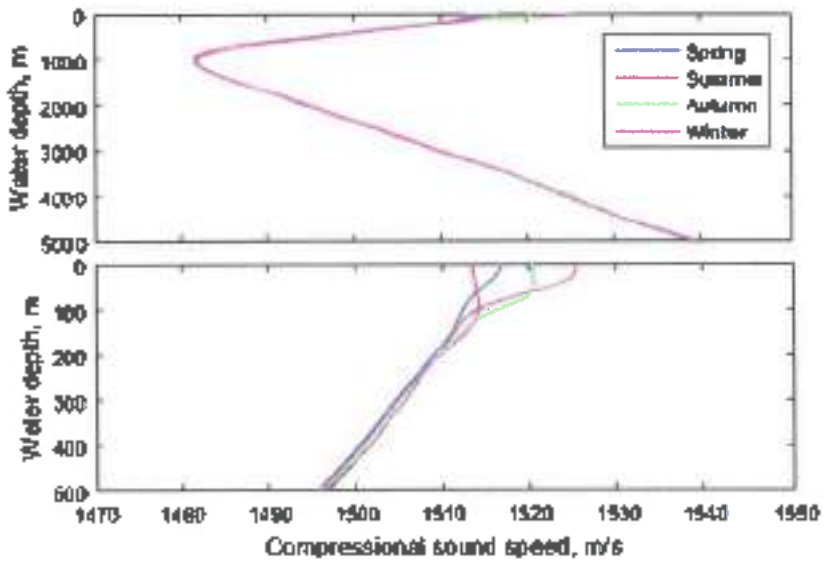
SLR

for calculation of the sound speed based on depth and latitude of each particular sample was obtained using Sanders and Fofonoff's formula (Sanders and Fofonoff 1976). The sound speed profiles were derived based on Del Grosso's equation (Del Grosso 1974).

Figure 9 presents the typical sound speed profiles for four seasons around the survey area. The figure demonstrates that the most significant distinctions for the profiles of four seasons occur within the mixed layer near the surface. The summer season has the strongest downwardly refracting feature among the four seasons, and the winter season exhibits a deeper surface duct than the other three seasons. Due to the stronger surface duct within the profile, it is expected that the winter season will favour the propagation of sound from a near surface acoustic source array. Based on a conservative consideration, winter season sound speed profile was selected as the modelling input.

As can be seen in the figure below, the overall speed profiles of different seasons across the water column are quite similar, although in shallower water (less than 200 m) there is slight seasonal variation. As such, the differences in sound fields between different seasons are not expected to be significant.

Figure 9 **Typical sound speed profiles within the survey area for different Southern Hemisphere seasons. The top panel shows profiles across the entire water column, and the bottom panel shows profiles across the water column section near the surface**



4.1.3 Seafloor Geoacoustic Model

To inform the 2018 national marine ecosystem classification and mapping efforts in southern Africa, Sink et al. (2019) collated sediment data from numerous samples acquired by grab or core under 13 different projects to produce a national layer of sediment types for southern Africa and adjacent ocean regions. The data sample classification reveals that the seafloor of the Western South African and Namibia shelves is primarily composed of mud sediment with a noticeable proportion of sand.

Relevant literature also shows that from continental shelf to deep sea basin, the sediment spatial distribution has general transition from sand/mud to deep sea ooze sediment, as a result of the regional

SLR

oceanography and terrigenous sediment supply, as well as the deep-sea sedimentary processes (Dingle et al. 1987; Dutkiewicz et al. 2015).

For the stratified layers beneath the superficial sediment layer within the offshore Orange Basin, relevant geological modelling studies (Paton et al. 2007; Campher et al. 2009) show that, for a typical east-west trending transect across the Orange Basin, a dominant layer of leaky shale/mudstone is predicted to be up to 2,000 m – 4,000 m from the seabed depth, followed by layers of sandstone and rock basement.

Based on above, as well as a conservative consideration, it was proposed that for the entire modelling area, the seafloor geoacoustic model comprises of a 50 metre thick fine and silty sand sediment layer, followed by a soft to set-cemented mudstone/shale sediment layer and a semi to full-cemented mudstone /shale substrate as detailed in Table 7. The geoacoustic properties for silty mud and sand are as described in Hamilton (1980), with attenuations referred to Jensen et al (2011). The elastic properties of silt and sand are treated as negligible.

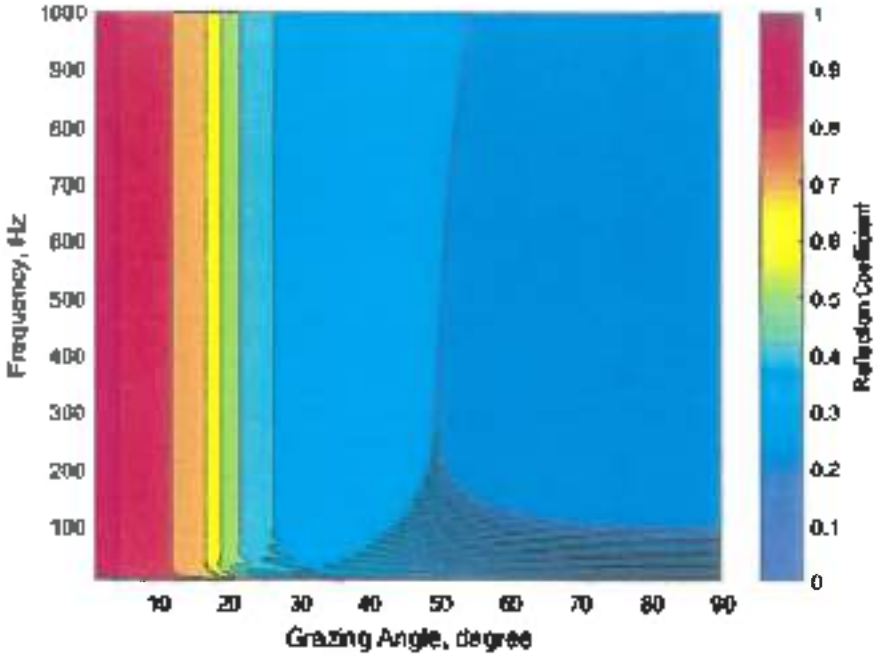
Figure 10 shows the reflection coefficient variation with grazing angle and frequency for the proposed seafloor geoacoustic scenario, calculated using the plane-wave reflection coefficient model (Porter 2001, 2020). As shown in the figure, the seafloor acoustic reflection is dominated by the top sediment layer across the frequency range, with high reflection at low grazing angles and low reflection (high refraction) at higher grazing angles.

Table 7 Geoacoustic parameters for the proposed seafloor model

Seafloor Materials	Depth Range, m	Density, ρ, (kg.m^{-3})	Compressional Wave	
			Speed, c_p, (m.s^{-1})	Attenuation, α_p, (dB/λ)
Fine/silty sand	0 - 50	1,900	1,650	0.8
Soft to semi-cemented mudstone / shale sediment layer	50 - 500	2,000	1,900	1.0
Semi-/full- cemented mudstone /shale half-space	500 - ∞	2,300	2,500	1.0

SLR

Figure 10 **Reflection coefficient vs grazing angle and frequency for the proposed geoacoustic model**



4.2 Methodology and Procedure

The sub-sections below describe the modelling methodologies and procedures for predicting received noise levels of relevant metrics associated with seismic survey activities.

The modelling components as detailed in Section 4.2.1 to Section 4.2.5 involve SELs and noise levels in relevant acoustic metrics (i.e., Peak SPLs and RMS SPLs) for single shots from the G-Gun II 3,370 CUI Source Array for the 3D seismic survey, as well as for the cumulative SELs within a 24-hour period for the representative 3D survey scenarios.

4.2.1 Short Range Modelling

Short range modelling has been used to model received SELs in relatively close proximity to the airgun source, with consideration of the near-field effect of the sound field. As such, the predictions for the short range case are modelled by reconstructing the received signal waveforms from individual airgun source units within the array.

The wavenumber integration modelling algorithm SCOOTER (Porter 2001, 2020) is used to calculate the transfer functions (both amplitudes and phases) between sources and receivers. SCOOTER is a finite element code for computing acoustic fields in range-independent environments. The method is based on direct computation of the spectral integral and is capable of dealing with an arbitrary layered seabed with both fluid and elastic characteristics.

The following procedures have been followed to calculate received SELs for short range cases:

SLR

1. The modelling algorithm SCOOTER is executed for frequencies from 1 Hz to 1 kHz, in 1 Hz increments. The source depth is taken to be the array depth of 8.0 m. A receiver grid of 1 m in range (maximum range 4.0 km) and 1 m in depth is applied for the selected receivers. For each gridded receiver, the received SEL is calculated by following steps 2) – 5);
2. The range from the source to each receiver is calculated, and the transfer function between the source and the receiver is obtained by interpolation of the results produced by modelling algorithm SCOOTER in Step 1). This interpolation involves both amplitude and phase of the signal waveform in frequency domain;
3. The complex frequency domain signal of the notional signature waveform for each source element is calculated via Fourier Transform, and multiplied by the corresponding transfer function from Step 2) to obtain the frequency domain representation of the received signal from the source element;
4. The waveform of received signal from the array source is reconstructed via Inverse Fourier Transform. The received signal waveforms from all airgun sources in the array are summed to obtain the overall received signal waveform; and
5. The signal waveform is squared and integrated over time to obtain the received SEL value. Alternatively, the SEL value can also be calculated via integration of the energy power density (ESD) over frequency in Step 3).

4.2.1.1 Modelling scenarios

The modelling inputs for the short range modelling case, such as sound speed profile and seabed geoacoustic models, has been detailed in Section 4.1. To analyse the received SEL variations with water depth changes, modelling has been undertaken for four (4) water depth cases for the 3D survey area (i.e., 1,900 m, 2,500 m, 3,100 m, and 3,700 m).

4.2.2 Long Range Modelling

The long range modelling generally involves complex and variable environmental factors (such as sound speed profiles and bathymetric variations) along an extended range of sound propagation environments, and requires an efficient modeling prediction algorithm with reasonable accuracy. Therefore, the modelling prediction for the long range case is carried out using the far-field source levels of octave frequency bands and their corresponding transmission loss calculations.

The fluid parabolic equation (PE) modelling algorithm RAMGeo (Collins 1993) is used to calculate the transmission loss between the source and the receiver. RAMGeo is an efficient and reliable PE algorithm for solving range-dependent acoustic problems with fluid seabed geo-acoustic properties.

The received sound exposure levels are calculated following the procedure as below:

1. One-third octave source levels for each azimuth to be considered are obtained by integrating the horizontal plane source spectrum over each frequency band, these levels are then corrected to SELs;
2. Transmission loss is calculated using RAMGeo at one-third octave band central frequencies from 8 Hz to 1 kHz, with a maximum range of 200 km and at 5-degree azimuth increments. The bathymetry variation along each modelling track is obtained via interpolation from the bathymetry dataset;

SLR

TZ28

3. The one-third octave source SEL levels and transmission loss are combined to obtain the received SEL levels as a function of range, depth and frequency.
4. The overall received SEL levels are calculated by summing all frequency band SEL levels.

4.2.2.1 Source locations

Three (3) long range modelling source locations are proposed for the 3D seismic survey as detailed in **Table 8** and shown in **Figure 11**. The modelling is representative of the noise propagation within the proposed 3D seismic area. Source location L1 is adjacent to the marine sensitive area, L2 represents the average depth of the south survey area and L3 is located towards the deeper water environment of the survey area.

Table 8 Details of the three selected source locations for the long range modelling

Source Location	Water Depth, m	Coordinates (Easting, Northing)	Locality
L1	1,900	(411159, 6653271)	north of the survey area adjacent to Childs Bank marine sensitive area
L2	3,100	(515091, 6394105)	mid-south of the survey area with average depths
L3	3,600	(396685, 6393331)	west of the survey area towards deeper water environment

Figure 11 The selected three source locations (L1, L2, & L3) indicated as orange dots. The white polygon shows the proposed 3D seismic survey area.

SLR

5708

4.2.3 Cumulative SEL Modelling

The cumulative SEL accounts for the total acoustic energy received from all seismic impulses within a specific period of exposure (i.e., 24 hours). There will be thousands of survey shots during a typical survey operation within a 24-hour period, and it is not practical to perform sound modelling for every survey shot in an efficient manner. However, the propagation environments for a set of consecutive survey shots are similar, and therefore one propagation model could be performed as representative for the set group. The sound field for the representative survey shot then could be adjusted to represent the rest of the survey shots within the set group accounting for their source positions.

The cumulative SELs (frequency unweighted and weighted) are modelled based on the steps as below:

1. The received SELs at individual grid locations (a 100-m grid size for this study) from individual representative survey shot considered (one in every ten shots for this study) is modelled based on the long range modelling methodology and procedure as detailed in Section 4.2.2 and then the results are adjusted for the rest of survey shots based on their shot locations;
2. The SEL_{24hr} at individual receiving grid locations are obtained by summing SEL contribution from all survey shots within a 24-hour period for the survey operation scenario considered;
3. For weighted SEL_{24w} for individual marine mammal hearing groups, the source spectra are adjusted accounting for the frequency weighting functions for individual hearing groups (as in Appendix B), and the weighted SEL_{24} for individual hearing groups to be obtained by repeating the first two steps as above; and
4. For high frequency energy component which is important for marine mammals with high frequency hearing range, the source spectra and propagation modelling are extended up to 10 kHz, with the source spectra being close to $1/f$ attenuation for frequencies above 1 kHz (Landrø et al. 2011), so that the high frequency energy component to be included for the weighted SEL_{24} predictions.

It should be noted that the source level inputs for long range modelling as detailed in Section 4.2.2 are based on the array source noise emissions in the horizontal plane, and this approach may underestimate the actual sound field close to the array source (< 4 km). As such, the sound fields close to the array source predicted by the long-range modelling as described in Step (1) above are benchmarked against short range modelling results to account for the near-field effects.

4.2.3.1 Survey Scenarios

Based on relevant project information provided, the survey schedules for the survey are outlined in Table 9. One survey line section is assumed to be acquired within the 24-hour period for each scenario.

Table 9 Survey Schedule

Survey	Shot spacing (m)	Vessel Speed (knots)	Survey Orientation
3D	12.5	4.5	NW-SE

The survey line details for the modelling scenario is detailed in Table 10 and indicated in Figure 12. The rationale of the selected cumulative modelling scenarios is on the basis that the scenarios are representative with regards to the adjacent EBSAs (i.e., Childs Bank and Cape Canyon) and MPAs. The modelling is representative of the noise propagation within the proposed 3D seismic area.

SLR

Line 2	1	[462322, 6591680]	80	near to EBSAs and MPAs
Line 3	1	[341354, 6605670]	80	northwest of the survey area towards deeper water environment

Figure 12 Representation of the selected three (3) Cumulative SEL 24-hour survey scenarios

4.2.4 Pk SPLs and RMS SPLs – Estimate Methodology from Modelled SELs

For received individual signals emitted from impulsive sources such as seismic airguns, the differences between the SEL and other sound parameters, such as the Pk SPL/RMS SPL, are expected to be greatest at the source location, and then gradually decrease with receiving locations further away from the source location. This is due to the following effects:

- Theoretically, the airgun pulse goes through increasing waveguide distortion effects (e.g., dispersion, interference effects, seafloor and surface reflections, differences of time arrivals, etc.) with increasing range from the source, which impact predominantly on temporal characteristics of the pulse (e.g., lower peak level, extended pulse duration, etc.) rather than the energy based metric levels.
- The above statement is reliably supported by numerous theoretical and empirical research studies, e.g., the relevant seismic survey signal modelling and measurement studies (e.g., Austin et al. 2013, Matthews and MacGillivray 2013, Galindo-Romero et al. 2015, McCauley et al. 2000,

SLR

5028

2016) show that the differences between the three temporal parameters (i.e., Pk SPL, and RMS SPL) and SEL are increasingly higher at the receiver closer to the source location.

4.2.4.1 SEL and Pk SPL

As presented in Section 3.3.2, the difference between the Pk SPL and SEL of the far-field signature of the source arrays (at a reference distance of 1 m from the centre of the array) is 24.0 dB for the 3D array. This value is taken as the conversion factor applied to the SELs for calculating the received Pk SPLs over the receiving range close to the source location. This approach is regarded as conservative for estimating relevant near-field acoustic parameters based on SEL predictions.

4.2.4.2 SEL and RMS SPL

Previous empirical studies demonstrate that at relatively close distances from the airgun sources (within 1.0 km), the difference between SELs and RMS SPLs could be between 10 dB to 15 dB (Austin et al. 2013; McCauley et al. 2000). The differences could drop to under 5 dB when the distances are close to 10 km (Austin et al. 2013). The differences are expected to drop further with the increasing distances beyond 10 km (Simon et al. 2018).

For this project, the RMS SPLs were estimated using the following conversion factors to be applied to the modelled SELs within different distance ranges.

These conversion factors are conservatively estimated based on the source array modelling results and above previous measurement results:

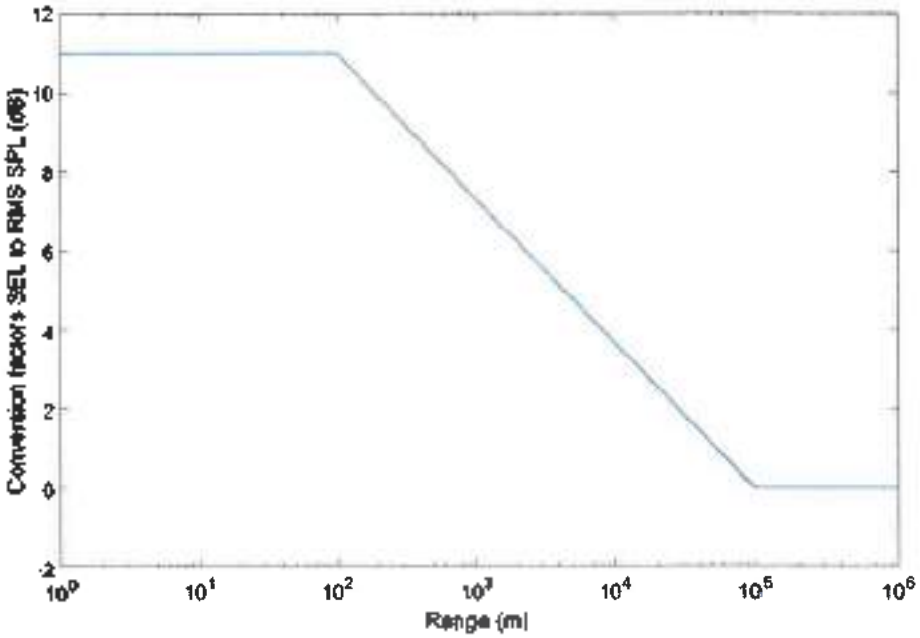
- 0 – 100 m, a conversion factor of 11 dB. This is the difference between RMS SPL and SEL of the far-field signature of the 3 370 cubic inch (CUI) G-Gun II array as modelled in Section 3.3.2;
- 100 – 1,000 m, conversion factors 11 dB to 10.0 dB, following a logarithmic trend with distance;
- 1,000 – 10,000 m, conversion factors 10.0 dB to 5.0 dB, following a logarithmic trend with distance;
- 10,000 – 100,000 m, conversion factors 5.0 dB to 0.0 dB, following a logarithmic trend with distance; and
- > 100,000 m, a conversion factor of 0.0 dB.

The SEL to RMS SPL conversion factors as a function of horizontal ranges from source array are demonstrated in Figure 13.

SLR

8018

Figure 13 SEL to RMS SPL conversion factors as a function of horizontal range from source array



4.2.5 Model Validation – Airgun Seismic Survey Noise Modelling

The accuracy of airgun array sound field modelling depends on the suitability and accuracy of the airgun array source model and the transmission loss model, as well as the realism of the parameters defining the sound propagation environment, including the bathymetry, seafloor geo-acoustics and sound speed profiles (DOC 2016).

The following model validation exercises have been undertaken previously in regards to the airgun array source model, short range model and long range model that have been used in this modelling study:

- The source modelling software Gundalf has been calibrated against various datasets of near-field recorded signatures, and has been verified against other airgun array source signature models (Ainslie et al. 2016); and
- The short range model and long range model have been validated from a few underwater acoustic measurement programs undertaken by independent third parties, with good agreements between modelled and measured results being reported (e.g., Simon et al. 2018; Li et al. 2021).

SLR

808

5.0 Modelling Results

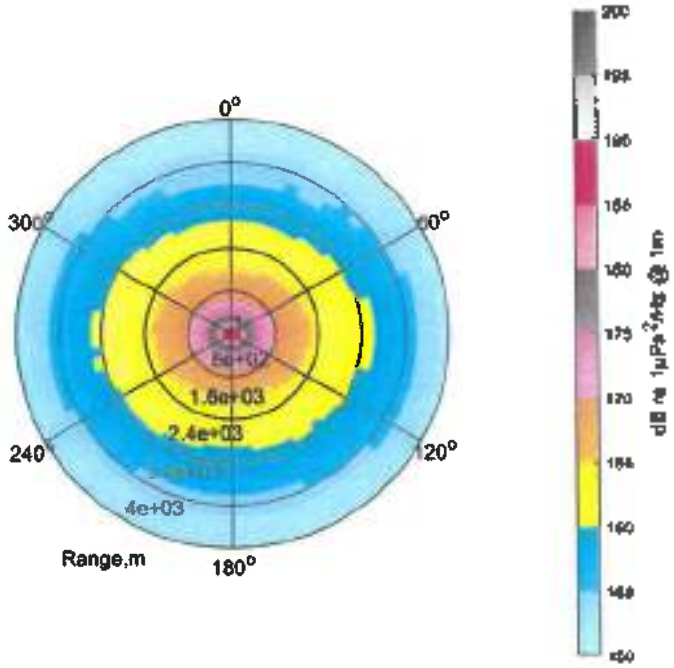
This section presents the modelling results for seismic surveys which include three modelling components (i.e., short range modelling, long range modelling and cumulative noise exposure modelling).

5.1 Short Range Modelling

The received SELs have been modelled for four (4) water depth cases for the 3D survey area (i.e., 1,900 m, 2,500 m, 3,100 m, and 3,700 m) from the G-Gun II 3 370 CUI source array.

Taking the 2,200 m water depth case as an example, Figure 14 shows the maximum received SELs across the water column for a single survey shot as a function of azimuth (0 – 360°) and near-field horizontal range (0 – 4 km) from the centre of the array. The figure illustrates slightly higher SEL levels in the cross-line directions as a result of the directionality of the source array.

Figure 14 **The predicted maximum SELs across the water column as a function of azimuth and horizontal range from the centre of the array. The 0-degree azimuth corresponds to the in-line direction. Water depth: 1,900 m**



The scatter plots of the predicted maximum SELs across the water column for all azimuths as a function of horizontal range (0 – 4 km) from the source array are displayed in Figure 15 for all relevant water depth cases. It is noted from the figure:

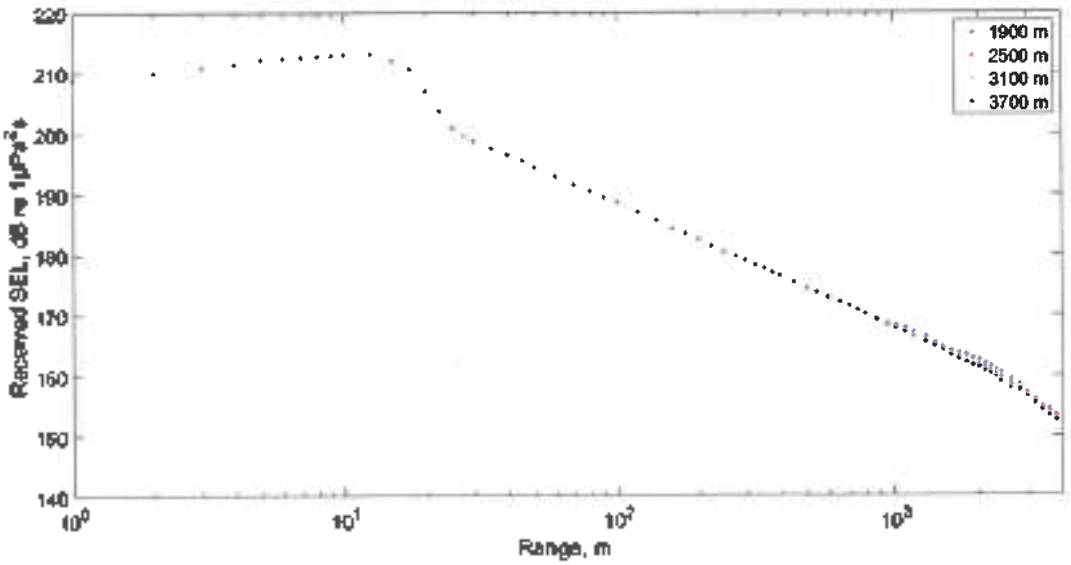
(a) For the proposed 3D seismic survey, the maximum received SELs for the four depth cases are nearly identical, as the water depths are all much higher than the deep water Sound Fixing and Ranging (SOFAR) channel (~1,000 m), and the maximum SELs are expected to be dominated by direct arrival acoustic energy from the array source.

SLR

1523

(b) At horizontal distances further away from the array centre (> 1 000 m), the maximum received SELs are predicted to be slightly higher for 1 900 m and 2 500 m water depths. This is because the sound field of a shallower water depth has the highest acoustic energy reflected from the seabed among the water depth cases.

Figure 15 The predicted maximum SELs across the water column for all azimuths as a function of range (0 – 4 km) from the source locations for the 3D source array



5.2 Long Range Modelling

Figure 16 shows the horizontal contour image of the predicted maximum SELs received at locations up to 200 km from source location L1, overlaying the local bathymetry contours. Figure 17 shows the vertical contour images of predicted SELs across the water column along the propagation paths to the west, east, north and south of the modelled location.

Both horizontal and vertical contour images for all other long range modelling locations are attached in Appendix D.

As can be seen from the horizontal and vertical contour figures, the received noise levels at far-field locations vary at different angles and distances from the source locations. This directivity of received levels is due to a combination of the directivity of the source array, and propagation effects caused by bathymetry and sound speed profile variations.

In general, the bathymetry profiles with significant upslope section across the continental slope region have the sound propagations experiencing significant attenuation due to the strong interaction between the sound signal and the seabed. The bathymetry profiles with downslope section have much less sound attenuation. These effects are evident in all locations for propagation paths towards shoreline directions.

For all source locations and except for downslope sections, the seabed depth variations are not significant along the propagation paths within the deep-water region. Therefore, the directivity of received noise is dominated by the directionality of the source array.

SLR

Figure 16 **Modelled maximum SEL (unweighted and maximum level across water column) contours for source location L1 to a maximum range of 200 km, overlayed with bathymetry contour lines. Coordinates in WGS 84/UTM Zone 33S.**

SLR

FR23

5.3 Cumulative SEL Modelling

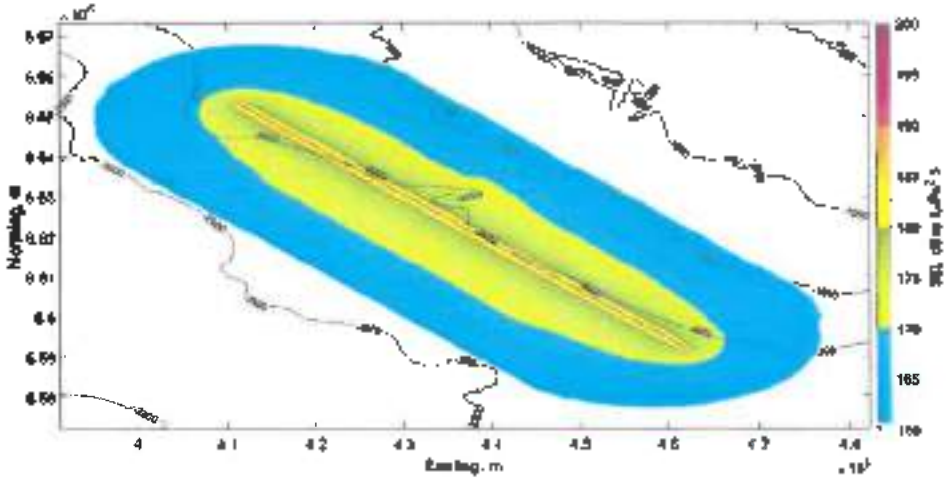
The sound exposure contributions from adjacent survey shots vary with the distances from the receiving locations to the survey line. From the short range modelling results as presented in Section 5.1, sound exposure level from a survey shot received at a receiving location with a distance of 1.0 km is predicted to be up to 30 dB lower than the level from a survey shot at a close distance of 30 m.

With the receiving location perpendicularly further away from the survey lines, the distance differences between the survey location and adjacent survey shots become smaller, and the sound exposure contributions from adjacent multiple shots along the survey lines become more significant proportionally compared with the survey shots closer to the survey lines. Based on this consideration, cumulative modelling is carried out for a modelling area within a 60 km zone around the survey lines and with a 100 metre grid size, so that the modelling area is sufficiently large to include all potential zones of impact for assessed marine fauna species.

The cumulative SEL modelling has been carried out for the 24-hour survey operation scenarios as described in Section 4.2.3.1, based on the modelling methodology and procedure as laid out in Section 4.2.3, for unweighted SEL_{24} case and weighted SEL_{24} cases with frequency weighting functions of different marine mammal hearing groups applied.

The modelled unweighted SEL_{24h} contour map for survey scenario S1 of the 3D seismic survey is presented in Figure 18. All other survey scenarios are attached in Noise Modelling Figures

Figure 18 The predicted maximum unweighted SEL_{24h} across the water column for assessed survey scenario S1 (Line 1) for the 3D survey



5.4 Zones of Impact - Immediate Exposure from Single Pulses

Based on the noise modelling prediction results presented above, the single pulses immediate exposure zones of impact (i.e., maximum horizontal threshold distance from array source location/survey lines) for marine fauna species of interest are summarized as follows.

Table 11 below outlines the predicted maximum SELs and the estimated Pk SPLs and RMS SPL across the water column for all azimuths as a function of horizontal distance from the seismic airgun source array.

SLR

5208

for water depth range within the survey area, based on the short range SEL modelling results as in Section 5.1 and relevant estimate approach as in Section 4.2.4.

Table 11 The maximum SELs, Pk SPLs and RMS SPL across the water column for all azimuths as a function of distance from the source array for water depth range within the 3D survey area

Horizontal distance from the source array, m	The predicted maximum levels across the water column for all azimuths, for water depth range within the survey area		
	SEL, dB re 1 μPa²·s	Pk SPL, dB re 1μPa	RMS SPL, dB re 1μPa
10	213	237	224
20	207	231	218
50	194	218	205
80	191	214.5	201.5
100	189	213	200
200	182	206	193
500	174	198	185
800	170	194	180
1 000	168	192	178
2 000	162	185	170
4 000	156	180	163

The zones of impact from seismic surveys based on per-pulse SEL, Pk SPL and RMS SPL metrics are estimated and presented in Table 12 for PTS and TTS effects for marine mammals, Table 13 for fish, Table 14 for sea turtles, and Table 15 for behavioural disturbance for marine mammals and sea turtles.

5.4.1 Marine Mammal Physiological Effects

Due to the high level of impulsive signal emissions from the array source, marine mammals are predicted to experience a permanent auditory threshold shift (PTS) at close proximity to the source arrays due to the immediate exposure to individual pulses. Based on zones of impact estimated Pk-SPL metric criteria as in Table 12 marine mammals of all hearing groups except very-high-frequency cetaceans are predicted to experience PTS effect within approximately 50 m from the 3D source array at all assessed water depth scenarios. The maximum zones of PTS effect for very-high-frequency cetaceans are predicted to be within 325 m from the 3D array source.

The zones of a temporary auditory threshold shift (TTS) due to a single pulse exposure for marine mammals of all hearing groups except very-high-frequency cetaceans are predicted to be within approximately 100 m from the source array. The maximum zones of TTS effect for very-high-frequency cetaceans are predicted to be within 650 m from the array source as presented in Table 12.

It should be noted that the zones of immediate impact assessed are for the airgun array source under the full-power operation condition (with an operating pressure of 2,000 psi). During the soft start process,

SLR

203

the airgun array source is under reduced operating pressure conditions, and consequently has lower noise emissions.

As such, the zones of impact during the soft start process are predicted to be less than the full-power operation condition. As an example, under a reduced operating pressure of 1,000 psi, the noise emissions from the airgun array source is approximately 6 dB lower than from the full-power operation, and the resulted zones of impact are estimated to be approximately half of those zones assessed under the full-power operation condition.

Table 12 Zones of immediate impact from single seismic airgun array pulses for PTS and TTS – marine mammals

Marine mammal hearing group	Zones of impact – maximum horizontal distances from source to impact threshold levels			
	Injury (PTS) onset		TTS onset	
	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m
Low-frequency cetaceans (LF)	219	45	213	90
High-frequency cetaceans (HF)	230	21	224	27
Very-high-frequency cetaceans (VHF)	202	325	196	650
Sirenians (SI)	226	25	220	40

5.4.2 Fish Physiological Effects

For seismic surveys, as presented in **Table 13**, the zones of potential injuries for fish species with a swim bladder, fish eggs and fish larvae are predicted to be within 180 m from the airgun array source.

However, fish species without swim bladders have higher injury impact thresholds, and therefore have smaller zones of potential injuries within 90 m from the airgun array source.

SLR

1528

Table 13 Zones of immediate impact from single airgun array pulses for mortality and recovery injury– fish, turtles, fish eggs and fish larvae

Type of animal	Zones of impact – maximum horizontal distances from source to impact threshold levels			
	Mortality and potential mortal injury		Recovery injury	
	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m
Fish: no swim bladder (particle motion detection)	>213	90	>213	90
Fish: swim bladder is not involved in hearing (particle motion detection)	>207	180	>207	180
Fish- swim bladder involved in hearing (primarily pressure detection)	>207	180	>207	180
Fish eggs and fish larvae	>207	180	-	-
Note: A dash indicates the threshold is not applicable.				

5.4.3 Sea Turtle Physiological Effects

The sea turtles are predicted to experience PTS effect in the close proximity to the source array due to the immediate exposure to individual pulses within approximately 19 m. The maximum zones of TTS due to a single pulse exposure for sea turtles are predicted to be within approximately 24 m from the array source as presented in Table 14.

Table 14 Zones of immediate impact from single seismic airgun array pulses for PTS and TTS – sea turtles

Type of animal	Zones of impact – maximum horizontal distances from source to impact threshold levels			
	Injury (PTS) onset		TTS onset	
	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m	Criteria - Pk SPL dB re 1µPa	Maximum threshold distance, m
Sea turtles	232	19	226	24
Note: A dash indicates the threshold is not applicable.				

5.4.4 Marine Mammal, Fish and Sea Turtle Behavioural Responses

The zones of behavioural disturbance for marine mammals and turtles caused by the immediate exposure to individual seismic airgun array pulses for seismic surveys are presented in Table 15 below.

SLR

The results show that behavioural disturbance caused by the immediate exposure to individual pulses are predicted to be within 3.8 km from the array source for marine mammals of all hearing groups, and within 1.3 km from the array source for sea turtles.

Based on the noise exposure criteria provided by Popper et al. (2014), relatively high to moderate behavioural risks are expected for fish species at near to intermediate distances (tens to hundreds of meters) from the source location. Relatively low behavioural risks are expected for fish species at far field distances (thousands of meters) from the source location.

Table 15 Zones of immediate impact from single seismic airgun array pulses for behavioural disturbance – marine mammals and sea turtles

Type of animal	Zones of impact – maximum horizontal distances from source to impact threshold levels	
	Behavioural disturbance	
	Criteria - RMS SPL, dB re 1µPa	Maximum threshold distance, m
Marine mammals	160	3,800
Sea turtles	175	1,300

5.5 Zones of Impact – Cumulative Exposure from Multiple Pulses

As described in Section 5.3, for seismic surveys, the cumulative sound fields in unweighted SEL_{24h} and weighted SEL_{24h} with relevant frequency weighting functions applied are modelled based on an assumed survey scenario for the 3D survey.

The zones of cumulative impact for seismic surveys (i.e., the maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels) are estimated based on the above modelling results. Table 16 presents the cumulative PTS and TTS effects for marine mammals, and Table 17 the cumulative mortality, injury and TTS effects for fish; and Table 18 the cumulative PTS and TTS effects for sea turtles.

5.5.1 Cumulative Impacts for Marine Mammals

For seismic surveys, among marine mammals of all six hearing groups, low-frequency cetaceans have the highest zones of PTS and TTS impact, as can be seen in Table 16. The zones of PTS impact are predicted to range up to 340 m from the source location, from the adjacent survey lines for the relevant typical 24-hour survey operation scenarios considered, and the maximum zone of TTS impact is predicted to be around 5 km from their relevant adjacent survey lines.

The cumulative PTS and TTS criteria SEL_{24h} are predicted not to be exceeded for high-frequency cetaceans, sirenians and other marine carnivores in water.

The cumulative PTS criteria SEL_{24h} are predicted to be exceeded for both very-high-frequency cetaceans and phocid carnivores in water, with zones of impact within 40 m from the adjacent survey lines. For very-high frequency cetaceans the zones of TTS impact are predicted to range around 1,200 m from the source location, and for phocid carnivores in water around 500 m from the source location, from the relevant adjacent survey lines for the 24-hour survey operation scenario considered.

It should be noted that the cumulative zones of impact presented above are conservative, and since cetaceans are highly mobile, they are likely to have moved considerable distances away from the source over the cumulative survey period. Thus, cumulative effects would only be expected where the animals do not move away from the area, e.g., from specific coastal areas used as calving sites of from feeding focal points such as Tripp Seamount. As Tripp Seamount is approximately 70 km from the north point of the survey area, cumulative effects would not be expected.

Table 16 Zones of cumulative impact from multiple airgun array pulses of the 3D survey for PTS and TTS – marine mammals

Marine mammal hearing group	Zones of impact – maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels			
	Injury (PTS) onset		TTS onset	
	Criteria – Weighted SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m	Criteria – Weighted SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m
Low-frequency cetaceans (LF)	183	340	168	5,050
High-frequency cetaceans (HF)	185	-	170	-
Very-high-frequency cetaceans (VHF)	155	40	140	1,200
Sirenians (SI)	203	-	175	-
Phocid carnivores in water (PCW)	185	10	170	500
Other marine carnivores in water (OCW)	203	-	188	-

Note: A dash indicates the threshold is not reached.

5.5.2 Cumulative impacts for fish

As presented in Table 17, the zones of potential mortal injuries for fish species with a swim bladder, fish eggs and fish larvae are predicted to be within 30 m from the adjacent survey lines for all the 24-hour survey operation scenarios considered. For recoverable injury, the zones of impact are predicted to be within 80 m from the adjacent survey lines for fish with a swim bladder for all the operation scenarios considered. Fish without swim bladder are not expected to suffer or any potential injury. The zones of TTS effect for fish species with and without swim bladders are predicted to be within 2.9 km, from the adjacent survey lines for the 24-hour survey operation scenario considered.

Existing experimental data regarding recoverable injury and TTS impacts for fish eggs and larvae is sparse and no guideline recommendations have been provided. However, based on a subjective approach as indicated in Table 3, noise impacts related to recoverable injury and TTS on fish eggs and larvae are expected to be moderate at the near field from the source location. Impact is expected to be low for all of them at intermediate and far field from the source location.

SLR

5408

Table 17 Zones of cumulative impact from multiple airgun array pulses of 3D surveys for mortality and recovery injury – fish, fish eggs and fish larvae

Type of animal	Zones of impact – maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels					
	Mortality and potential mortal injury		Recoverable injury		TTS	
	Criteria - SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m	Criteria - SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m	Criteria - SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m
Fish: no swim bladder (particle motion detection)	219	-	216	-	186	2,900
Fish: swim bladder is not involved in hearing (particle motion detection)	210	10	203	80	186	2,900
Fish: swim bladder involved in hearing (primarily pressure detection)	207	30	203	80	186	2,900
Fish eggs and fish larvae	210	10	-	-	-	-

Note: A dash indicates the threshold is not applicable.

5.5.3 Cumulative impacts for sea turtles

Noise impacts related to recoverable injury and TTS on sea turtles are expected to be high at the near field from the source location as shown in Table 18 maximum zones of PTS impact are predicted to range within 10 m from the source location, from the adjacent survey line for the relevant typical 24-hour survey operation scenario considered. The maximum zones of TTS impact are predicted to be around 500 m.

Table 18 Zones of cumulative impact from multiple airgun array pulses of the survey for PTS and TTS – sea turtles

Type of animal	Zones of impact – maximum horizontal perpendicular distances from assessed survey lines to cumulative impact threshold levels			
	Injury (PTS) onset		TTS onset	
	Criteria – Weighted SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m	Criteria – Weighted SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m
Sea turtles	204	10	189	500

SLR

JZ03

6.0 Discussion

As detailed in **Section 2.0**, dual metric criteria (i.e., per-pulse impact criteria Pk SPL and cumulative exposure impact criteria SEL_{24hr}) are applied to assess PTS and TTS impact for marine mammals, and mortality and recovery injury for fish and sea turtles. The combined threshold distance for each impact effect is considered as the maximum threshold distances (i.e., the worst-case scenario) estimated from either metric criteria being applied.

For marine mammals, the combined zones of impact from seismic surveys for all six hearing groups based on estimated results in **Table 12** and **Table 16** are presented in **Table 19**. As can be seen, the cumulative noise exposure results in extended zones of PTS and TTS impact for low-frequency cetaceans, and extended zones of TTS impact for very-high-frequency cetaceans and phocid carnivores in water.

Table 19 Combined zones of impact from airgun array pulses for PTS and TTS – marine mammals

Marine mammal hearing group	Combined zones of impact – maximum horizontal distances to either Pk SPL or cumulative SEL threshold levels			
	Injury (PTS) onset		TTS onset	
	Criteria applied - Pk SPL, dB re 1 µPa / Weighted SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m	Criteria applied - Pk SPL, dB re 1 µPa / Weighted SEL_{24hr} dB re 1 $\mu Pa^2 \cdot s$	Maximum threshold distance, m
Low-frequency cetaceans (LF)	183 Weighted SEL_{24hr}	340	168 Weighted SEL_{24hr}	5,050
High-frequency cetaceans (HF)	230 Pk SPL	21	224 Pk SPL	27
Very-high-frequency cetaceans (VHF)	202' Pk SPL	325	140 Weighted SEL_{24hr}	1,200
Sirenians (SI)	226 Pk SPL	25	220 Pk SPL	40
Phocid carnivores in water (PCW)	218 Pk SPL	50	170 Weighted SEL_{24hr}	500
Other marine carnivores in water (OCW)	232 Pk SPL	19	226 Pk SPL	24

The combined zones of mortal and recoverable injury impact from seismic surveys for fish species are the zones of impact estimated based on immediate impact criteria Pk SPL as in **Table 13** and the zones of TTS impact from seismic surveys for fish species based on cumulative impact criteria SEL as in **Table 17**

For sea turtles, the combined zones of impact from seismic surveys based on the noise criteria for PTS and TTS are presented in **Table 14** and **Table 18**.

For marine seismic surveys, the cumulative exposure level at certain locations is modelled based on the assumption that the animals are constantly exposed to the survey airgun noise at a fixed location over the entire 24-hour period.

SLR

However, in reality marine fauna species, such as marine mammals, fish species and sea turtles, would not stay in the same location for the entire period unless individuals are attached to a specific feeding or breeding area or those species that cannot move away (e.g., plankton and fish eggs/larvae).

Therefore, the zones of impact assessed for marine mammals, fish species and sea turtles represent the worst-case consideration.

6.1 Recommended Management Measures

This section includes recommended management measures from seismic survey activities related to zones of impact and implementation of a noise monitoring programme and soft-starts.

- Noise Monitoring Programme – a best practice to minimize the potential for deliberate injury to marine mammal by monitoring a defined area (safety zone) before a noise source is activated and delaying operations in the event a marine mammal is observed.
- Safety zones – these are observation and shut-down zones sized based on the likely noise levels produced by the seismic activity.
- Soft-starts – these procedures are recommended for all seismic activities, irrespective of location and time of year, when marine mammal species may potentially be present within the noise footprint of the seismic activity.

6.1.1 Noise Monitoring Programme

Baseline noise measurements can provide useful information (prior to operations) when interpreting underwater noise predictions for the introduction of a new noise source. As such, it is recommended that underwater noise measurements be implemented which would include the deployment of underwater sound monitoring equipment to establish an actual baseline prior to the commencement of the survey and then operational levels of noise during the survey.

Additionally, monitoring can be further achieved through a combination of visual and passive acoustic methods. No marine mammal detection method is 100% effective for all species, rather it is considered that these methods seek to complement each other.

Visual monitoring is done by a Marine Mammal Observer (MMO). It should be done from the source vessel with the MMO located on a suitable platform that allows the best view of the safety zone and ahead of the vessel.

The use of Passive Acoustic Monitoring (PAM) is a viable monitoring method during operation periods when effective visual monitoring (due to poor visibility conditions or during night) is not possible. Specialist trained PAM operators are needed to set up and deploy the equipment and to interpret detected sounds.

6.1.2 Safety Zones

Recommended safety zones around the survey vessel and seismic array based on the seismic activity to be performed:

- Immediate Exposure from Single Pulses – refer to maximum threshold distances in PTS for marine mammals and sea turtles, and potential mortal injury for fish.

- Cumulative Exposure from Multiple Pulses - refer to maximum threshold distances in PTS for marine mammals and sea turtles, and potential mortal injury for fish.

6.1.3 Soft-Starts

Implement a soft-start procedure if testing multiple seismic sources. The soft-start should be carried out over a time proportional to the number of seismic sources being tested and not exceed 20 minutes; source arrays should be tested in order of increasing volume.

- If testing the seismic source at full operational capacity, a 20-minute soft-start is required.
- If testing a single lowest power source, a soft-start is not required.
- Delay soft-starts if shoaling large pelagic fish, turtles, or marine mammals are observed within the zone of impact.
- A soft-start should not begin until 30 minutes after cetaceans depart the zone of impact or 30 minutes after they are last seen or acoustically detected in the zone of impact.
- Schedule soft-starts to minimise, as far as possible, the interval between reaching full power operation and commencing a survey line. The period between the end of the soft start and commencing with a survey line must not exceed 20 minutes.

6.1.4 Cumulative impacts from multiple simultaneous survey campaigns

In the unlikely event that multiple surveys would take place at the same time within the same survey area, the risk of cumulative noise impact must be considered and is suggested to be managed as follows:

- The maximum number of simultaneous surveys in the entire survey area would be limited to three;
- Each of the additional activities to that described in this report would be modelled or otherwise considered in terms of the cumulative noise level and with reference to the criteria described in this report; and
- During airgun releases, each survey vessel is at least 40 kilometres from any other survey vessel until sufficient objective evidence is obtained to demonstrate that a reduced buffer distance is acceptable

Note: This 40km buffer maintained by any other survey vessels aligns to advice by authorities[4] and is considered sufficient on the basis that it provides a corridor between vessels where airgun noise approaches ambient levels such that animals may pass between, and/or the potential cumulative effect beyond this distance is considered to be negligible. Further modelling is only considered required in the case where a 40 km buffer distance between active survey ships cannot be maintained.

Acoustic Terminology

1/3 Octave Band Levels	The energy of a sound split into a series of adjacent frequency bands, each being 1/3 of an octave wide
Decibel (dB)	The decibel (abbreviated dB) is the unit used to measure the intensity of a sound on a logarithmic scale.
Peak Sound Pressure Level (Pk SPL)	The peak sound pressure level is the logarithmic ratio of the peak pressure over the impulsive signal event to the reference pressure
Peak-to-Peak Sound Pressure Level (Pk-Pk SPL)	The peak-to-peak sound pressure level is the logarithmic ratio of the difference between the maximum and minimum pressure over the impulsive signal event to the reference pressure
Power Spectral Density (PSD)	PSD describes how the power of a signal is distributed with frequency
Root-Mean-Square Sound Pressure Level (RMS SPL)	The mean-square sound pressure is the average of the squared pressure over the pulse duration. The root-mean-square sound pressure level is the logarithmic ratio of the root of the mean-square pressure to the reference pressure. Pulse duration is taken as the duration between the 5% and the 95% points on the cumulative energy curve
Sound Exposure Level (SEL)	SEL is a measure of energy. Specifically, it is the dB level of the time integral of the squared instantaneous sound pressure normalised to a 1-s period
Sound Pressure	A deviation from the ambient hydrostatic pressure caused by a sound wave
Sound Pressure Level (SPL)	The logarithmic ratio of sound pressure to the reference pressure. The reference pressure underwater is P_{ref} = 1 µPa
Sound Speed Profile	A graph of the speed of sound in the water column as a function of depth
Source Level (SL)	The acoustic source level is the level referenced to a distance of 1 m from a point source

Auditory Weighting Functions

This appendix provides the recommended frequency-weighting functions for use in assessing the effects of relatively intense sounds on hearing. This information is derived based on all available relevant data and published literature (i.e., the state of current knowledge).

Marine animals do not hear equally well at all frequencies within their functional hearing range. Based on the hearing range and sensitivities, Southall et al. (2019) have categorised marine mammal species (i.e., cetaceans and pinnipeds) into six underwater hearing groups: low-frequency (LF), high-frequency (HF), very high-frequency (VHF) cetaceans, Sirenians (SI), Phocid carnivores in water (PCW) and Other marine carnivores in water (OCW). For each specific marine mammal species, refer to Appendix I – 6 within the reference document (Southall et al. 2019) for their corresponding hearing groups.

The potential noise effects on animals depend on how well the animals can hear the noise. Frequency weighting is a method of quantitatively compensating for the differential frequency response of sensory systems (Southall et al., 2019)

When developing updated scientific recommendations in marine mammal noise exposure criteria, Southall et al. (2019) adopted the auditory weighting functions as expressed in the equation below, which are based on the quantitative method by Finneran (2016) and are consistent with the U.S. National Oceanic and Atmospheric Administration (NOAA) technical guidance (NMFS, 2016 & 2018). Finneran et al. (2017) revised the auditory-weighting functions for sea turtle (TU). Audiogram slopes were calculated across a frequency range of one octave for five species (refer to Appendix C) with composite audiograms based on experimental data.

$$W(f) = C + 10log10\left\{\frac{(f/f_1)^{2a}}{[1+(f/f_1)^2]^a[1+(f/f_2)^2]^b}\right\} \quad \text{(2.1)}$$

Where:

- $W(f)$ is the weighting function amplitude (in dB) at frequency f (in kHz).
- f_1 represents LF transition value (in kHz), i.e., the lower frequency at which the function amplitude begins to change from the flat, central portion of the curve.
- f_2 represents HF transition value (in kHz), i.e., the upper frequency at which the function amplitude begins to change from the flat, central portion of the curve.
- a represents the LF exponent value (dimensionless) which defines the rate of decline of the weighting function amplitude at low frequencies. The change in weighting function amplitude with frequency at low frequencies (the LF slope) is 20a dB/decade.
- b represents the HF exponent value (dimensionless) which defines the rate of decline of weighting function amplitude at high frequencies, becoming linear with the logarithm of frequency. The change in weighting function amplitude with frequency at high frequencies (the HF slope) is -20b dB/decade.
- C is the constant that defines the vertical position of the curve. It is defined so that the maximum amplitude of the weighting function equals 0 dB (with all other values being negative).

Table B.1 lists the auditory weighting parameters as defined above for the seven hearing groups. The corresponding auditory weighting functions for all hearing groups are presented in Figure B.1.

Table B.1 Auditory weighting functions - parameters (Southall et al. 2019; Finneran et al. 2017)

Marine mammal hearing group	*a*	*b*	*f1 (kHz)*	*f2 (kHz)*	*C (dB)*
Low-frequency cetaceans (LF)	1.0	2	0.20	19	0.13
High-frequency cetaceans (HF)	1.6	2	8.8	110	1.20
Very-high-frequency cetaceans (VHF)	1.8	2	12	140	1.36
Sirenians (SI)	1.8	2	4.3	25	2.62
Phocid carnivores in water (PCW)	1.0	2	1.9	30	0.75
Other marine carnivores in water (OCW)	2.0	2	0.94	25	0.64
Sea turtles (TU)	1.4	2	0.077	0.44	2.35

Figure B.1 Auditory weighting functions – spectral plots (Southall et al. 2019; Finneran et al. 2017)

Marine Mammal Classification

The following appendix gives a summary of marine mammal hearing group classification and sea turtles. Not all animals listed in **Table C.1** are expected to be found in the vicinity of the project area.

Table C.1 Summary of marine mammal classification

Classification	Common Name	Scientific Name
Low frequency cetaceans (extracted from Appendix 1 Southall *et al.* (2019))	Bowhead whale	*Balaena mysticetus*
	Southern right whale	*Eubalaena australias*
	North Atlantic right whale	*Eubalaena glacialis*
	North Pacific right whale	*Eubalaena japonica*
	Common minke whale	*Balaenoptera acutorostrata*
	Antarctic minke whale	*Balaenoptera bonaerensis*
	Sei whale	*Balaenoptera borealis*
	Bryde's whale	*Balaenoptera edeni*
	Omura's whale	*Balaenoptera omurai*
	Fin whale	*Balaenoptera physalus*
	Humpback whale	*Megaptera novaeangliae*
	Pygmy right whale	*Caperea marginata*
	Gray whale	*Eschrichtius robustus*
High frequency cetaceans (extracted from Appendix 2 Southall *et al.* (2019))	Sperm whale	*Physeter macrocephalus*
	Arnoux' beaked whale	*Berardius arnuxii*
	Baird's beaked whale	*Berardius bairdii*
	Northern bottlenose whale	*Hyperoodon ampullatus*
	Southern bottlenose whale	*Hyperoodon planifrons*
	Tropical bottlenose whale	*Indopacetus pacificus*
	Sowerby's beaked whale	*Mesoplodon bidens*
	Andrews' beaked whale	*Mesoplodon bowdoini*
	Hubb's beaked whale	*Mesoplodon carlhubbsi*
	Blainville's beaked whale	*Mesoplodon densirostris*
	Gervais' beaked whale	*Mesoplodon europaeus*
	Ginkgo-toothed beaked whale	*Mesoplodon ginkgodens*
	Gray's beaked whale	*Mesoplodon grayi*

SLR

5028

Classification	Common Name	Scientific Name
	Hector's beaked whale	*Mesoplodon hectori*
	Deraniyagala's beaked whale	*Mesoplodon hotaula*
	Layard's beaked whale	*Mesoplodon layardii*
	True's beaked whale	*Mesoplodon mirus*
	Perrin's beaked whale	*Mesoplodon perrini*
	Pygmy beaked whale	*Mesoplodon peruvianus*
	Stejneger's beaked whale	*Mesoplodon stejnegeri*
	Spade-toothed whale	*Mesoplodon traversii*
	Tasman beaked whale	*Tasmacetus shepherdi*
	Cuvier's beaked whale	*Ziphius cavirostris*
	Killer whale	*Orcinus orca*
	Beluga	*Delphinapterus leucas*
	Narwhal	*Monodon monoceros*
	Short- and long-beaked common dolphins	*Delphinus delphis*
	Pygmy killer whale	*Feresa attenuata*
	Short-finned pilot whale	*Globicephala macrorhynchus*
	Long-finned pilot whale	*Globicephala melas*
	Risso's dolphin	*Grampus griseus*
	Fraser's dolphin	*Lagenodelphis hosei*
	Atlantic white-sided dolphin	*Lagenorhynchus acutus*
	White-beaked dolphin	*Lagenorhynchus albirostris*
	Pacific white-sided dolphin	*Lagenorhynchus obliquidens*
	Dusky dolphin	*Lagenorhynchus obscurus*
	Northern right whale dolphin	*Lissodelphis borealis*
	Southern right whale dolphin	*Lissodelphis peronii*
	Irrawaddy dolphin	*Orcaella brevirostris*
	Australian snubfin dolphin	*Orcaella heinsohni*
	Melon-headed whale	*Peponocephala electra*
	False killer whale	*Pseudorca crassidens*
	Indo-Pacific humpback dolphin	*Sousa chinensis*
	Indian Ocean humpback dolphin	*Sousa plumbea*

SLR

Classification	Common Name	Scientific Name
	Australian humpback dolphin	*Sousa sahulensis*
	Atlantic humpback dolphin	*Sousa teuszii*

	Pantropical spotted dolphin	*Stenella attenuata*
	Clymene dolphin	*Stenella clymene*
	Striped dolphin	*Stenella coeruleoalba*
	Atlantic spotted dolphin	*Stenella frontalis*
	Spinner dolphin	*Stenella longirostris*
	Rough-toothed dolphin	*Steno bredanensis*
	Indo-Pacific bottlenose dolphin	*Tursiops aduncus*
	Common bottlenose dolphin	*Tursiops truncatus*
	South Asian river dolphin	*Platanista gangetica*
Very high frequency cetaceans (extracted from Appendix 3 Southall *et al.* (2019))	Peale's dolphin	*Lagenorhynchus australis*
	Hourglass dolphin	*Lagenorhynchus cruciger*
	Commerson's dolphin	*Cephalorhynchus commersonii*
	Chilean dolphin	*Cephalorhynchus eutropia*
	Heaviside's dolphin	*Cephalorhynchus heavisidii*
	Hector's dolphin	*Cephalorhynchus hectori*
	Narrow-ridged finless porpoise	*Neophocaena asiaeorientalis*
	Indo-Pacific finless porpoise	*Neophocaena phocaenoides*
	Spectacled porpoise	*Phocoena dioptrica*
	Harbor porpoise	*Phocoena phocoena*
	Vaquita	*Phocoena sinus*
	Burmeister's porpoise	*Phocoena spinipinnis*
	Dall's porpoise	*Phocoenoides dalli*
	Amazon river dolphin	*Inia geoffrensis*
	Yangtze river dolphin	*Lipotes vexillifer*
	Franciscana	*Pontoporia blainvillei*
	Pygmy sperm whale	*Kogia breviceps*
	Dwarf sperm whale	*Kogia sima*

SLR

Classification	Common Name	Scientific Name
Sirenians (extracted from Appendix 4 Southall et al. (2019))	Amazonian manatee	*Trichechus inunguis*

JONATHAN VALLARTA, Ph.D.

Underwater Acoustics Business Lead

EDUCATION

- Ph.D., School of Engineering and Physical Sciences, Heriot-Watt University, UK 2009
- B.Eng., Electronics & Communications (Hons), Ibero-American University Mexico 2001
- B.Sc., Biological Sciences, National Autonomous University of Mexico, 1999

EXPERTISE

- Underwater acoustics
- Passive Acoustic Monitoring
- PAM Localization
- Hydrophone-Arrays: design, implementation, and deployment
- Noise and wildlife
- Noise impact assessments
- Environmental noise monitoring
- Computer noise modeling

CERTIFICATIONS

- Basic Safety Course for Rigs and Mobile Offshore Units
- Mexican Seamans Book
- Medical Fit Certificate
- Master Suba Diving, NAUI

MEMBERSHIPS

- Acoustical Society of America, ASA
- International Association Impact Assessment, IAIA
- Mexican Society of Marine Mammals, SOMEMMA

Dr. Jonathan Vallarta has eighteen years of experience in underwater acoustics in a wide range of positions including teaching, design, project management, acoustic consulting, and collaborative research. His expertise is in the design of new configurations for hydrophone arrays and development of localization algorithms using passive sonar techniques to track the migratory patterns of cetaceans in areas where there is increased anthropogenic activity. He has considerable experience providing training courses in fundamentals of underwater noise and monitoring techniques.

Jonathan joined SLR in January 2020 and is based in Vancouver. His previous experience includes running a passive acoustic monitoring business, while lecturing several university courses and consulting for JASCO Applied Sciences over four years. Jonathan holds a Ph.D. from Heriot-Watt University in Edinburgh, Scotland, awarded for research into the significance of passive acoustic array configuration on sperm whale range estimation.

Jonathan has published numerous papers in academic journals and presented at various international conferences. In June 2018, his expertise was recognized as an invited panellist and as Mexican advisor to the United Nations Informal Consultative Process on Oceans and the Law of the Sea (UNICPOLOS) at the headquarters of the United Nations in New York. He has a particular interest in marine conservation issues, particularly in reference to threatened species, noise pollution and mitigation.

SELECT PROJECT EXPERIENCE

UNDERWATER ACOUSTICS PROJECTS

- **3D Seismic Survey Underwater Noise Modeling, West Coast of South Africa**
  Detailed underwater sound propagation modeling for 3D seismic survey activities were performed to assist with the assessment of a new source array with two high-volume active elements proved to have less impact on marine fauna species of interest (in terms of maximum zones) than the conventional airgun array.
- **Cumulative Effects of Marine Shipping on Esquimalt Nation Territory, Canada**
  The study analyzed numerous automatic identification system transits from 2019 of recreational and commercial vessels in the Salish Sea. Several peer-reviewed papers, and regional reports relevant to the impacts of underwater noise from commercial vessels on marine mammals were reviewed and assembled into a literature review matrix based on topics relevant to Esquimalt Nation.
- **2D Seismic Survey Underwater Noise Modeling, East Coast of South Africa**
  Detailed underwater sound propagation modeling for 2D seismic survey activities were performed to assist with the assessment of potential noise impact on marine fauna species of interest. The noise modelling results were then used to identify zones of impact for marine mammals and other species of concern based on relevant noise impact assessment criteria.
- **Tugboats Towing Drill Rig Underwater Noise Modeling, Cook Inlet, Alaska**
  Technical study on the underwater noise emissions from tugboats in various scenarios in Cook Inlet, Alaska. It included sound propagation modelling, understanding the range of different noise levels produced by tugs, and the distances at which tug noise is predicted to exceed impact assessment thresholds for marine mammals.
- **Offshore Wind Underwater Noise Impact Assessment, Lake Ontario**
  Technical study on underwater noise issues relevant to the project, identifying the relevant regulations and criteria and provided an assessment of potential project

SLR

5625

underwater noise impacts from dredging and tugboat noise specifically for the installation of 66 gravity base structures for turbine generators.

- **TOTAL Mozambique LNG Underwater Noise Analysis**
  Analysis and review of underwater noise impacts due to the construction of the Mozambique LNG project on Tungue Bay. Included an independent review of two modelling reports, analysis and recommendations of available piling noise attenuation options, verification of the impact of sound pressure thresholds on human divers and interpretation of the extent to which underwater noise levels may affect the catch rates for local fishermen, in mitigated and un-mitigated scenarios.
- **Alaska LNG, Cook Inlet, Alaska**
  Detailed frequency and range dependent underwater noise propagation modelling to identify the extent of project construction noise impacts on marine mammals, including the endangered Cook Inlet beluga whale. Included model validation with reference to historical measurements in Cook Inlet, and investigation of the sensitivity of results to variations in environmental parameters used as model inputs to determine realistic areas above defined thresholds.
- **Monitoring the Soundscape of Coral Reef, Cozumel, Mexico**
  A Passive Acoustic Monitoring (PAM) survey was conducted in the Paradise Coral Reef of Cozumel to obtain 1) the first scientific recording of the endangered splendid toadfish vocalizations; 2) record the volume and source of anthropogenic sounds on the coral reef; and 3) estimate possible impacts of anthropogenic noise (masking and exposure) on splendid toadfish. The project involved the deployment of PAM equipment by scientific personnel and scuba divers. Noise mitigation recommendations were provided to local authorities.
- **Sound Characterization of Pile Driving, Virginia, USA**
  Sound characterization of different test piling noise levels during the construction of a harbour terminal in Thimble Shoal, Virginia, USA. Assessment of marine and fish noise impacts and potential for project cumulative impacts.
- **Acoustic Modelling for VSP Offshore Operations, Australia**
  Acoustic modelling for assessing marine fauna sound exposures during Vertical Seismic Profiling (VSP) operations for the CarbonNet Offshore appraisal in Australia. The acoustic modelling included the use of parabolic equation and ray tracing methods.
- **Marine Mammal Acoustic Detections, Chukchi Sea, Artic**
  A five-year project in the northeast of the Chukchi Sea that included passive acoustic detections of bowhead whale and other marine mammals, while seismic exploration activities occurred during summer season every year. A passive acoustic localization algorithm was implemented to assess the impact of anthropogenic noise on the migration patterns of bowhead whale.
- **Modern LNG Carrier Sound Source Characterization, Trinidad**
  Underwater acoustic monitoring at one of the LNG port sites of Trinidad in order to obtain a sound source characterization of modern LNG carriers. The emphasis of this project was due to the lack of data registered and the need to acoustically model the noise levels of a new LNG station in Canada.
- **Acoustic Modelling and Monitoring of the Tappan Zee Bridge, New York**
  Underwater acoustic monitoring during the pile installation project of the new Tappan Zee Bridge. The project included both underwater acoustic modelling and monitoring as a validation method for the different pile driving tests. Assessment of several mitigation techniques, such as different types of bubble curtains, were also modelled and monitored.
- **Underwater Acoustic Monitoring of Power Plant, Dominican Republic**
  Underwater passive acoustic monitoring of an active Power Plant close to offshore in the Dominican Republic. The initiative came along from the need to explore the noise level impacts on manatees and fish. Noise mitigation recommendations were given to local authorities and project managers.

SLR

UNDERWATER ACOUSTICS WORKSHOPS

- **SOMEMMA, La Paz-Baja California 2021.** A one-day virtual acoustic workshop based in La Paz, Baja California to train scientists in PAMGuard software as the preamble to the international meeting for the study of marine mammals "Research, Conservation Foundation".
- **TRITON Environmental Consultants, Vancouver-BC 2020.** A two-day acoustic workshop based in Vancouver to train three scientists in PAMGuard software to engage in acoustic monitoring of offshore dredging in Prince Rupert, BC.
- **Edgewise Environmental, St John's-Newfoundland 2019.** A four-day acoustic workshop based in St. John's to address the need to train new passive acoustic monitoring operators to engage in seismic exploration vessels in the Arctic Sea.
- **TALOS Energy, Villahermosa-Tabasco 2019.** A two-day acoustic workshop based in Villahermosa to train two new passive acoustic monitoring operators to engage in VSP offshore operations in the Gulf of Mexico by TALOS Energy Company.
- **CICESE, Ensenada-Baja California 2018.** A three-day acoustic workshop based in Ensenada to address the specific needs of a Center for Scientific Research and Higher Education, CICESE.
- **PAMOS, Mexico City-Mexico 2015-2017.** A three-day acoustic workshop based in Mexico City to address the need to train new passive acoustic monitoring operators to engage in seismic exploration vessels in the Gulf of Mexico.

EDUCATION

- University of Delaware

  Ph.D. Oceanography (Acoustical Oceanography) 2009 - 2016

- Florida Institute of Technology

  MS in Ocean Engineering (Ocean Instrumentation), 2007 – 2009

  BS in Ocean Engineering (Hydrographic Surveying), 2003 - 2007

EXPERTISE

- Underwater acoustics
- Underwater noise modelling
- Target localization using beamforming methods
- Passive acoustic monitoring
- Physical oceanography
- Ocean engineering
- Ocean instrumentation
- Advanced signal processing
- Data analysis
- High-performance computational methods with large data sets

SOFTWARE SKILLS

- Matlab (GPU and Parallel Processing)
- dBSea (underwater sound transmission loss modelling)
- Large (multiple TBs) dataset analysis
- BELLHOP (ray tracing)
- Parabolic Equation & Normal Modes Modelling

Dr. Justin Eickmeier is an experienced researcher and consultant with nine years of graduate studies and three years of post-doctoral work in Acoustical Oceanography at the University of Delaware. He joined SLR's underwater acoustics team in February 2019 and has quickly become involved in managing and delivering underwater noise consulting projects, specifically marine mammal impact assessments. In addition to underwater acoustics projects, he has supported the wider SLR acoustics group in a signal processing/data analyst role. Beginning in June 2019, he was on a 1-year secondment to the Port of Vancouver's ECHO (Enhancing Cetacean Habitat and Observation) program and continues to provide technical support on underwater acoustics. At the start of 2022, Justin took on the role of Underwater Acoustics Team Lead for SLR Canada.

Before joining SLR, Dr. Eickmeier's research focus areas were collecting and analyzing acoustical and ocean environmental data from the Arctic (Beaufort Sea) during the Canadian Basin Acoustic Propagation Experiment (CANAPE). His field research experience followed the completion of BS and MS degrees in Ocean Engineering at the Florida Institute of Technology, specializing in hydrographic surveying and ocean instrumentation, respectively.

Dr. Eickmeier has participated in numerous research cruises in the Arctic and elsewhere in the Atlantic and Pacific. His role on these projects has included working autonomously or in small teams, designing, deploying, and recovering multi-sensor oceanographic moorings, undertaking acoustic monitoring using hydrophone arrays, and analyzing acoustic data, including marine mammal detections, ambient noise, and contributions from anthropogenic noise sources. He specializes in managing large data sets collected during long-term (multi-year) monitoring experiments.

His substantial experience in underwater acoustics complements Dr. Eickmeier's background in oceanography, ocean engineering, and instrumentation. His technical skills include underwater noise propagation modelling and prediction, measurement and monitoring, data processing and analysis, impact assessment, mitigation, and control.

SELECTED PROJECT EXPERIENCE

- **Nilcorp, Tugboat Underwater Noise in Cook Inlet, Alaska 2021**

  Technical study predicting the underwater noise emissions from tugboats in various marine construction scenarios in Cook Inlet, Alaska. This study was prepared to understand the range of different noise levels produced by tugs and the distances at which tug noise is predicted to exceed impact assessment thresholds for marine mammals.

- **Baird, Technical Advice on Underwater Noise for Offshore Wind Project, Ontario 2021**

  The Windstream Wolfe Island Shoals Wind Energy Project is located 5 km off the southwest shore of Wolfe Island, in Lake Ontario. This technical advice report describes underwater noise issues relevant to the project, identifies relevant regulations and criteria, and assesses potential underwater noise impacts via sound transmission loss modelling for wind turbine installation,

including marine construction, dredging, dynamic position systems, and transits of commercial vessels.

- **Hilcorp Cook Inlet Exploration Drilling, Alaska 2019**
  SLR International Corporation prepared an environmental impact analysis of Hilcorp's proposed four-well 2020 outer continental shelf exploration drilling program in the Cook Inlet. As project manager and technical lead for SLR Canada's portion of the assessment, a desktop study identifying the baseline noise environment and the underwater noise impacts of the proposed activities (drill rig tow, impact pile driving, drilling, and vertical seismic profiling) considering marine mammal behavioral disturbance thresholds was undertaken.

- **Vancouver Fraser Port Authority Enhancing Cetacean Research and Observation (ECHO) Program, British Columbia 2019 - 2022 (ongoing)**
  - Technical guidance to program managers within the ECHO Program
  - Salish Sea ambient noise study and best practices report
  - Evaluation of underwater radiated noise from commercial vessels, quieting technology, energy savings devices, and hybrid propulsion systems.

- **Confidential Client Offshore Seismic Survey, Brazil 2019**
  Project manager for a desktop underwater noise impact assessment, predicting extents of various zones of marine mammal impact during a large-scale offshore seismic survey. Project requirements included coordinating SLR team members in Australia and Canada and working on a tight schedule to meet client targets.

- **Lehigh Hanson Materials, British Columbia 2019 & 2021**
  Data analyst supporting ongoing airborne noise monitoring for a quarry in Sechelt, British Columbia (2019). Data collection and analysis for a 2-week overnight airborne noise study (2021).

- **TransLink, British Columbia 2019**
  Data analysis and signal processing support for ongoing SkyTrain noise mitigation studies, including axle box vibration data analysis to infer rail surface conditions).

RESEARCH EXPERIENCE

- **Post-Doctoral Research, University of Delaware, 2016 - 2018**
  Advanced signal processing of broadband acoustic data and water column measurements in shallow water environments. Specialization in managing large data sets (including multi-year experiments) and high-performance computational methods.

  Dr. Eickmeier has extensive experience with beamforming (array localization) from multi-hydrophone arrays and modelling with rough boundary conditions and range-dependent environmental parameters using ray tracers, normal modes, and parabolic equation models.

  A passive acoustic study of soniferous fish and marine mammals in Delaware Bay included the acoustic classification of several species of fish native to Delaware Bay and the acoustic signatures of short-nosed common dolphins during daily feeding cycles.

  The design, fabrication, and deployment of 7 environmental arrays were completed for a year-long study in the Beaufort Sea. Array lengths spanned from 150 to 700 m, including 10 to 30 thermistors, 2 CTDs per mooring, and tandem acoustic release kits. High-frequency sampling rates on thermistors allowed for investigation of the acoustic waveguide, while low pass filtering matched time scales of fluctuations in upwelling and sub-mesoscale eddy formation.

DECLARATION OF THE ENVIRONMENTAL SPECIALIST

I, Jonathan Vallarta-Hernandez declare that –

General declaration:

- I act as an independent specialist in this application.
- I will perform the work relating to the application in an objective manner, even if this results in views and findings that are not favorable to the applicant.
- I declare that there are no circumstances that may compromise my objectivity in performing such work.
- I have expertise in conducting undertaking the specialist work as required, including knowledge of the Act, Regulations and any guidelines that have relevance to the proposed activity.
- I will comply with the Act, Regulations, and all other applicable legislation.
- I have not, and will not engage in, conflicting interest in the undertaking of the activity.
- I understand to disclose to the applicant and competent authority all material information in my possession that reasonably has or may have the potential of influencing- any decision to be taken with respect to the application by the competent authority, and the objectivity of any report, plan or document to be prepared by myself for submission to the competent authority.
- I have taken into account, to the extent possible, the matters referred to in Regulation 18 when preparing the report, plan or document.
- I will provide the competent authority with access to all information at my disposal regarding the application, whether such information is favourable to the applicant or not.
- All the particulars furnished by me this form are true and correct.
- I will perform all other obligations as expected from an environmental assessment practitioner in terms of the Regulations.
- I am aware of what constitutes an offence in terms of Regulation 48 and that a person convicted of an offence in terms of Regulation 48(1) is liable to the penalties as contemplated in Section 49B of the Act.

Disclosure of Vested Interest

I do not have and will not have any vested interest (either business, financial, personal or other) in the proposed activity proceeding other than remunerative for work performed in terms of the Regulations.

Signed/Sworn/Declared before me, at the City of Vancouver, British Columbia this 5th day of DECEMBER, 2022.

Signature of the Specialist:

Name of Company: SLR Consulting (Canada) Ltd.

Date: DECEMBER 5, 2022

1 INTRODUCTION

TGS Geophysical Company (UK) (hereafter TGS) has applied for Environmental Authorization for a 3D seismic survey off the West Coast of South Africa. Environmental Impact Management Services (Pty) Ltd (EIMS) has been appointed by TGS to prepare and submit an application for Environmental Authorisation (EA) as per the requirements of the Environmental Impact Assessment (EIA) Regulations, 2014, as amended, promulgated under the National Environmental Management Act (Act No. 107 of 1998- NEMA) and the requirements of the Minerals and Petroleum Resources Development Act (Act No. 28 of 2002 – MPRDA).

The proposed project area is located between approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km offshore of Hondeklip Bay over a number of petroleum licence blocks.

The area of interest for the proposed 3D seismic survey is approximately 57 400 km^2 in extent. It is proposed that a single survey vessel equipped with seismic sources and streamers be used. The proposed 3D survey would be supported by up to two escort vessels. The 3D survey will take in the order of 70 days including downtime.

The Environmental Management Programme (EMPr) has been compiled to meet the requirements for an EIA and as stipulated in the EIA Regulations, 2014. The competent authority for this application will be the Department of Mineral Resources and Energy (DMRE).

An EMPr is an environmental management tool used to ensure that undue or reasonably avoidable adverse impacts during the applicable phases of a development or activity are prevented, and that the positive benefits of the projects are enhanced. This EMPr has been compiled as a guideline for the mitigation and management measures to be implemented to avoid, reduce and minimise potential environmental impacts arising out of the project.

2 SCOPE OF THIS DOCUMENT

The purpose of the EMPr is to give effect to precautionary and mitigatory measures, which are to be put in place for controlling the activities that take place during the project. The EMPr also provides guidance to assist in ensuring compliance with relevant national legislative and regulatory requirements.

It should be borne in mind, however, that the EMPr is a working document that should be updated on a regular basis, as and when necessary. Formal risk identification forms an integral part of EMPr management and assists with prioritizing and focusing the control of risks. The EMPr thus supports this on-going proactive mitigation and the duty of care to the environment. The EMPr shall therefore allow for risk minimization, rather than just ensuring legal compliance. The purpose of this EMPr is thus also to allow the user to make minor amendments to ensure continual revision and improvement of risk mitigation through the continual re-assessment of risks associated with the activity.

3 DOCUMENT STRUCTURE

Table 1: EMPr Structure

Appendix 4 Reference	Description	Section in EMPr
Appendix 4(1)(1)(a)	Details of – (i) The EAP who prepared the EMPR; and (ii) The expertise of that EAP to prepare an EMPR, including a curriculum vitae;	Section 4
Appendix 4(1)(1)(b)	A detailed description of the aspects of the activity that are covered by the EMPR as identified by the project description.	Section 5
Appendix 4(1)(1)(c)	A map at an appropriate scale which superimposes the proposed activity, its associated structures, and infrastructure on the environmental sensitivities of the preferred site, indicating any areas that should be avoided, including buffers;	Section 6
Appendix 4(1)(1)(d)	A description of the impact management outcomes, including management statements, identifying the impacts and risks that need to be avoided, managed and mitigated as identified though the environmental impact assessment process for all phases of the development including – (i) Planning and design; (ii) Pre-construction activities; (iii) Construction activities; (iv) rehabilitation of the environment after construction and in the case of a closure activity, closure; and (v) Where relevant, operation activities;	Section 13
Appendix 4(1)(1)(f)	A description of proposed impact management actions, identifying the manner in which the impact management contemplated in paragraphs (d) will be achieved, and must, where applicable, include actions to – (i) Avoid, modify, remedy, control or stop any action, activity or process which causes pollution or environmental degradation; (ii) Comply with any prescribed environmental management standards or practices; and (iii) Comply with any applicable provisions of the act regarding closure, where applicable.	Section 13

1577

Appendix 4 Reference	Description	Section in EMPr
Appendix 4(1)(1)(g)	The method of monitoring the implementation of the impact management actions contemplated in paragraph (f);	Section 13
Appendix 4(1)(1)(h)	The frequency of monitoring the implementation of the impact management actions contemplated in paragraph (f);	Section 13
Appendix 4(1)(1)(i)	An indication of the persons who will be responsible for the implementation of the impact management actions;	Section 13
Appendix 4(1)(1)(j)	The time periods within which the impact management actions contemplated in paragraph (f) must be implemented;	Section 13
Appendix 4(1)(1)(k)	The mechanism for monitoring compliance with the impact management actions contemplated in paragraph (f);	Section 13
Appendix 4(1)(1)(l)	A program for reporting on compliance, taking into account the requirements as prescribed by the Regulations;	Section 13
Appendix 4(1)(1)(m)	An environmental awareness plan describing the manner in which – (i) The applicant intends to inform his or her employees of any environmental risk which may result from their work; and (ii) Risks must be dealt with in order to avoid pollution or the degradation of the environment; and	Section 11
Appendix 4(1)(1)(n)	Any specific information that may be required by the competent authority.	N/A

1578

4 REQUIREMENTS OF AN EAP

In terms of Regulation 13 of the EIA Regulations, 2014, an independent EAP, must be appointed by the applicant to manage the application. EIMS has been appointed by the Applicant as the EAP and is compliant with the definition of an EAP as defined in Regulations 1 and 13 of the EIA Regulations and Section 1 of the NEMA. This includes, inter alia, the requirement that EIMS is:

1) Objective and independent;

2) Has expertise in conducting EIA's;

3) Comply with the NEMA, the Regulations and all other applicable legislation;

4) Takes into account all relevant factors relating to the application; and

5) Provides full disclosure to the applicant and the relevant environmental authority.

The Curriculum Vitae (indicating the experience with environmental impact assessment and relevant application processes) of the consultants that were involved in the EMPr process, and the compilation of this report are attached as Appendix 1.

4.1 Details of the EAP

EIMS was appointed by the Applicant as the EAP to compile this report. The contact details of the EIMS consultants who compiled the report are as follows:

Table 2: EAP Details

Name of Practitioner	Mr GP Kriel (Report Compiler) & Mr Liam Whitlow (Reviewer)
Tel No.:	+27 11 789 7170
E-mail:	tgs@eims.co.za

4.2 Expertise of the EAP

EIMS is a private and independent environmental management-consulting firm that was founded in 1993. EIMS has in excess of 29 years' experience in conducting EIA's. Please refer to the EIMS website (www.eims.co.za) for further details of expertise and experience.

GP holds an M.Env.Sci (Water Sciences) Cum Laude from the North-West University (Potchefstroom Campus) and has been employed as an Environmental Consultant since 2007. GP is a Registered Professional Natural Scientist (South African Council for Natural and Scientific Professions) and a Registered Environmental Assessment Practitioner (Environmental Assessment Practitioner). He has delivered presentations locally and internationally concerning the use of bio-indicators for the determination of water quality, and has experience in a wide variety of environmental management projects including: Environmental Impact Assessments, Basic Assessments, Geographic Information Systems (GIS), Environmental Compliance Monitoring, Environmental Awareness Training, Aquatic Ecological Assessments, Drinking and Waste Water Treatment Process Audits, Wetland Delineation and Assessments, ISO 14001 Aspect Registers, Water Use Licence Applications, Waste Management Licence Applications, Integrated Waste and Water Management Plans (IWWMP) and Green House Gas Assessments.

Liam holds a B. Sc. Hons degree in Environmental Management and has completed an additional B. Sc. honours course in applied limnology. In addition, he has completed a higher certificate in Project Management with Damelin Business School and a course on ISO14001 Auditing Principles and Environmental Management Systems Auditor Training. Liam is a registered professional natural scientist with the South African Council for Natural Scientific Professions. Liam's professional experience, gained over more than 21 years, lies mainly with environmental impact assessments including project managing significantly large EIAs in the mining and infrastructure sectors. Liam's other experience includes ISO14001, Site Assessments, Water-use licensing, Environmental monitoring, and

Environmental Management Plans. Liam's experience lies mainly within South Africa, but he has been involved in projects in both Lesotho and Botswana.

The Curriculum Vitae of the EAP responsible for the compilation of this Report is included in Appendix 1.

5 PROJECT DESCRIPTION

This section provides an overview of the proposed activity

Seismic survey programmes comprise of data acquisition in either two-dimensional (2D) and/or three-dimensional (3D) scales, depending on information requirements. 2D surveys are typically applied to obtain regional data from widely spaced survey grids and provide a vertical profile through the subsurface, highlighting geophysical, geological information and features along the seismic line. Infill surveys on closer grids subsequently provide more detail over specific areas of interest. In contrast, 3D seismic surveys are conducted on a very tight survey grid spacing in specific target areas, often identified during 2D applications, providing a cube image of the subsurface geology within the survey volume. The current proposed seismic survey as discussed in this report is a 3D seismic survey and does not include any provision for exploration drilling.

During seismic surveys high-level, low frequency sound pulses are generated by an acoustic instrument towed behind a survey vessel, just below the sea surface. The sounds are directed towards the seabed and the seismic signal is reflected by the geological interfaces below the seafloor. The reflected signals are received by an array of receivers or sets of hydrophones towed behind the vessel in a single streamer (2D) or in multiple streamers (3D) and are fed back to the recording instruments on board. The spacing between the hydrophone groups is commonly 25 m or shorter, depending on the purpose of the seismic survey. Each group contains many hydrophones, spaced less than 1 m apart. The hydrophone streamers must be towed at constant depth (6 – 10 m), with flotation usually achieved by filling the cables with kerosene, gel or flexible polymer foam, so that they are neutrally buoyant. To compensate for minor adjustments, Automatic Cable Levellers, or "birds" are used. The ends of the hydrophone streamers are marked with tail buoys, to warn shipping about the presence of the cable in the water. The tail buoys also act as a platform for surface positioning systems so that the cable locations can be accurately monitored. Refer to Figure 1, Figure 2 and Figure 3 for illustrative examples of typical survey vessel, equipment and activities.

Figure 1: Example of seismic survey vessel and associated equipment (FishSAFE, 2021).

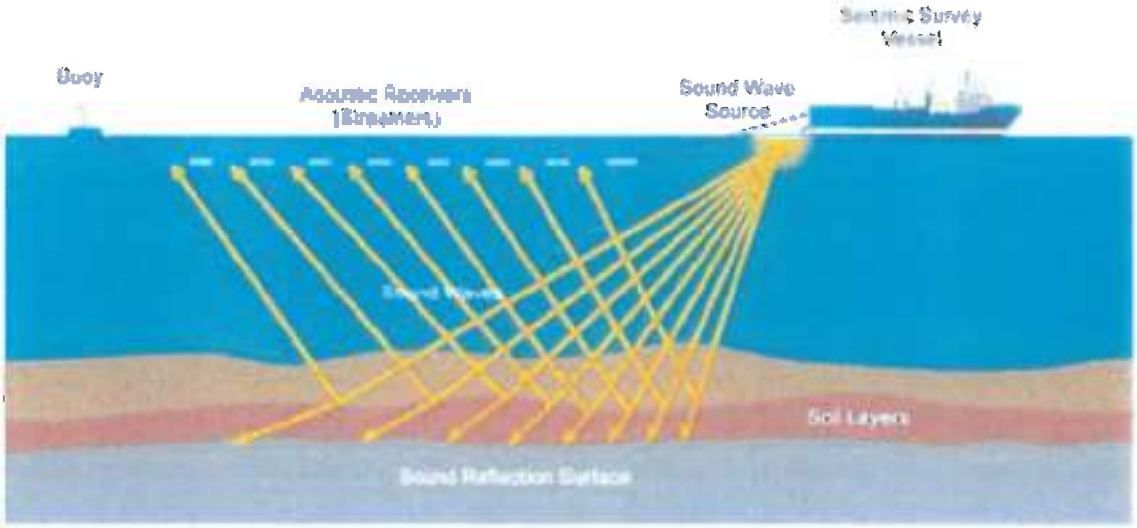

Figure 2: Example demonstration of seismic survey activities (Fish SAFE, 2021).

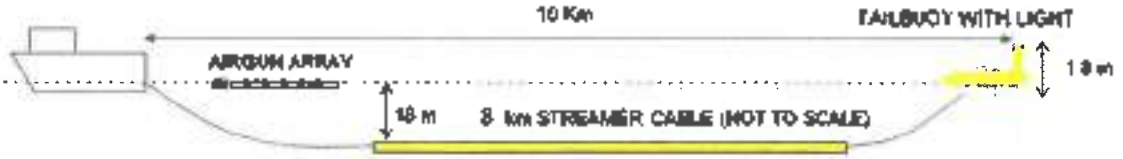

Figure 3: Schematic diagram showing side-view of the seismic source array and hydrophone cable ("streamer")

While acquiring the seismic data, the survey vessel would travel along transects of a prescribed grid within the survey area that have been chosen to cross any known or suspected geological structure in the area. The vessel typically travels at a speed of between four and six knots (i.e. 2 to 3 meters per second / 7.2 to 10.8 kilometres per hour) while surveying. The survey vessel length is approximately 100 m.

The proposed survey would involve a seismic sound source and multiple hydrophone streamers, which would be approximately 8 000 m long and 2 000 m wide. The streamers would be towed at a depth of 8 m below the surface and would not be visible, except for the tail-buoy at the terminal end of the cable. The array has an operating pressure of 2 000 pounds per square inch. The sound source would be towed behind the vessel at a depth of between 5 – 25 m below the surface. As the survey vessel would be restricted in manoeuvrability, other vessels should remain clear of it and therefore a support vessel usually assists in the operation of keeping other vessels at a safe distance.

Each triggering of a sound source is termed a seismic pulse, and these are discharged at intervals of 6 – 20 seconds (depending on water depth and other environmental characteristics). Each seismic pulse is usually only between 5 and 30 milliseconds in duration, and despite peak levels within each pulse being high, the total energy delivered into the water is low. Seismic sources have most of their energy in the 5-300 Hz frequency range, with the optimal frequency required for deep penetration seismic work being 50-80 Hz.

Sound levels from individual sound sources used today in the seismic industry range from 200 to 255 dB re 1 µPa at 1 m, for small to large individual seismic sources, respectively. For sound source arrays, sound levels range from 235 dB re 1 µPa at 1 m for a small array (500 cubic inches) to 260 dB re 1 µPa at 1 m for large arrays (7 900 cubic inches). The majority of the produced energy is below 250 Hz, with 90% of the energy between 70 to 140 Hz, although pulses do contain some higher frequencies up to 16 kHz. It must be noted, however, that the sound level specifications for sound source arrays refer to sound levels in the vertical direction directly beneath the sound source array, generally near its centre, with nominal sound levels in the horizontal direction being ~10-20 dB lower.

1509

6 SITE DESCRIPTION AND SENSITIVE AREAS

There are six offshore Marine Protected Areas (MPAs) in the general project area, but none fall within the Survey area. The proposed 3D survey area lies well offshore of these MPAs. Although there is no overlap of the 3D survey area with Ecologically and Biologically Significant Areas (EBSAs), critical biodiversity areas (CBAs) within the Reconnaissance Permit and 3D survey areas include both CBA1: natural and CBA2: natural areas (Figure 4). No no-go areas were identified.

1623

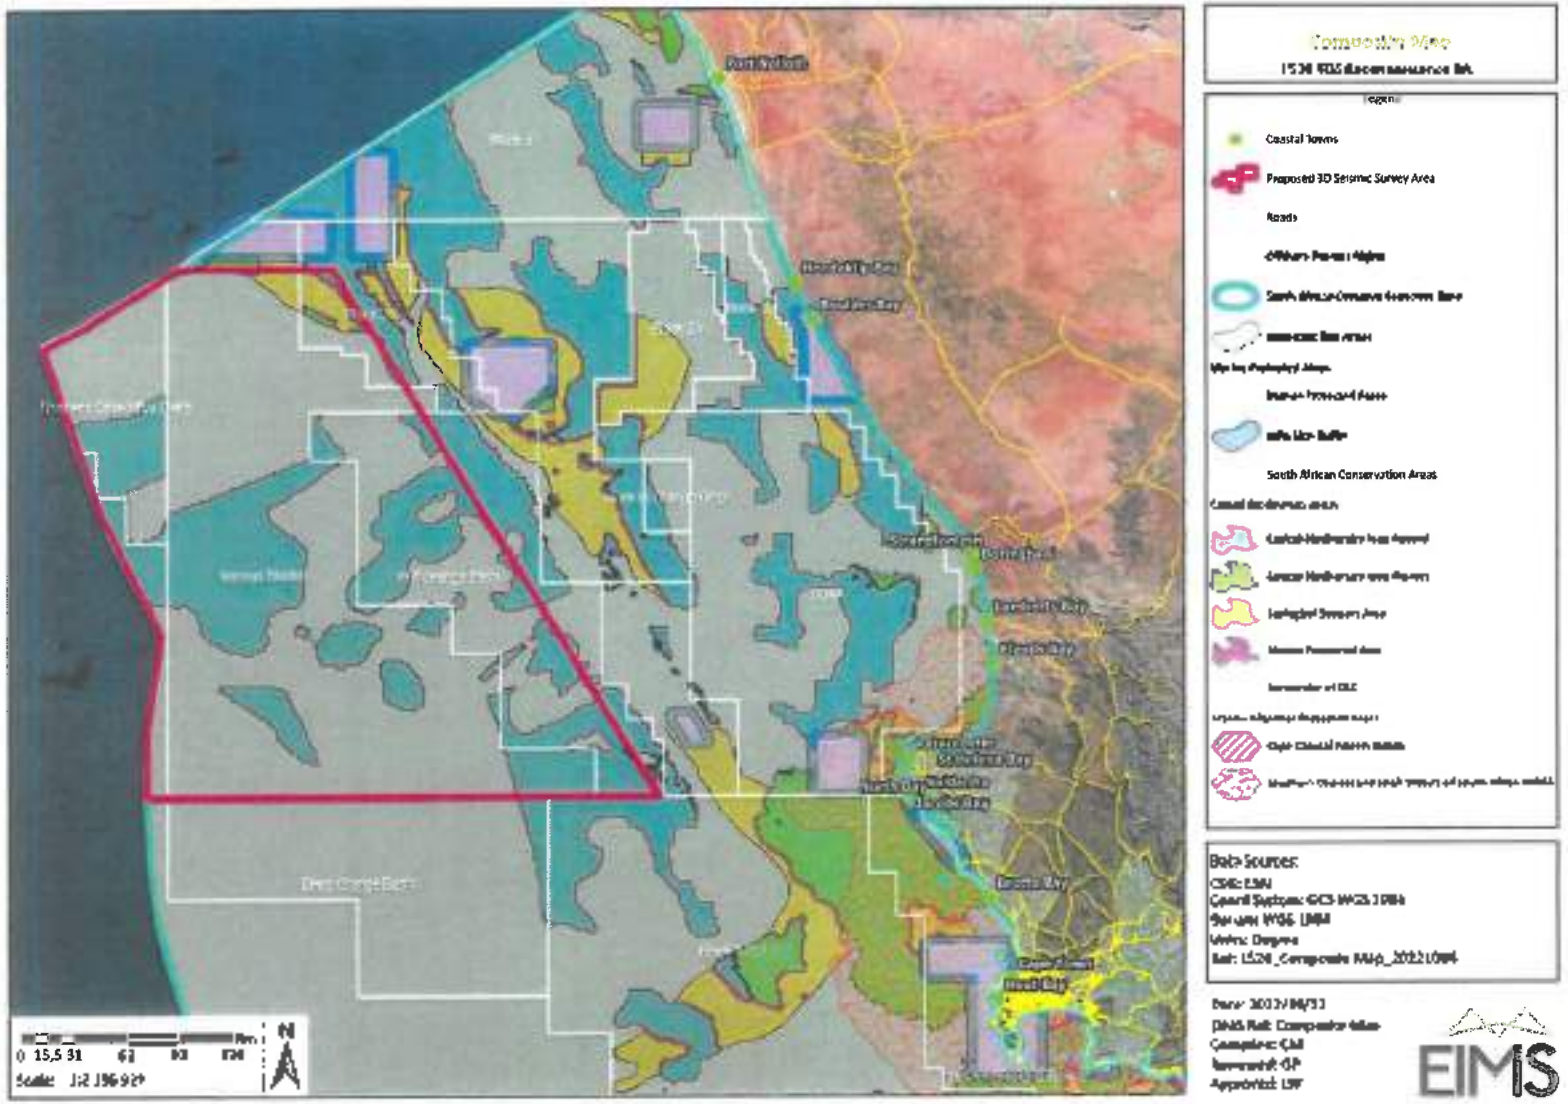

Figure 4: Locality/ sensitivity map showing the preferred site for the 3D Survey.

1583

Potential impacts associated with the proposed activity at the selected site have been identified and addressed in the EMPr and are summarised in the table below:

Table 3: Potential impacts identified in BA report

#	Impact	Phase
1	Impacts of seismic noise on mysticetes and odontocetes	Operation
2	Impacts of seismic noise on seals	Operation
3	Impacts of seismic noise on turtles	Operation
4	Impacts of seismic noise on diving seabirds	Operation
5	Impacts of seismic noise to pelagic fish	Operation
6	Impacts of seismic noise to marine invertebrates	Operation
7	Impacts of seismic noise to plankton and ichthyoplankton	Operation
8	Disturbance and behavioural changes in seabirds, seals, turtles and cetaceans due to vessel noise	Operation
9	Disturbance and behavioural changes in seabirds, seals, turtles and cetaceans due to noise of support aircraft	Operation
10	Disturbance and behavioural changes in pelagic fauna due to vessel lighting	Operation
11	Impacts of marine biodiversity through the introduction of non-native species in ballast water and on ship hulls	Operation
12	Impacts of normal vessel discharges on marine fauna	Operation
13	Impacts on turtles and cetaceans due to ship strikes, collision and entanglement with towed equipment	Operation
14	Impacts on benthic and pelagic fauna due to accidental loss of equipment to the seabed or the water column	Operation
15	Impacts of an operational spill or collision on marine fauna	Operation
16	Impacts of exclusion from fishing ground on the large pelagic longline sector due to the safety zone around the survey vessel	Operation
17	Impact of Exclusion of the Tuna Pole-Line Sector from access to Fishing Ground	Operation
18	Impact of Underwater Sound on the Large Pelagic Longline Sector	Operation
19	Impact of Underwater Sound on the Tuna Pole-Line Sector	Operation
20	Impacts of an operational spill on the large pelagic longline sector	Operation
21	Impacts of the unplanned loss of equipment to sea from the survey vessel	Operation

3628

#	Impact	Phase
22	Impacts on Cultural Heritage	Operation
23	Impacts of an operational spill or collision on marine fauna	Operation
24	Impacts on Cultural Heritage	Operation
25	Uncertainty	Planning
26	Concerns about cumulative impacts	Planning
27	Further marginalisation of vulnerable groups	Planning
28	Stakeholder fatigue and disillusionment	Planning
29	Perceived impact on livelihoods	Operation
30	Impacts on sense and spirit of place	Operation
31	Impacts on social licence to operate	Operation
32	Community expectations	Operation
33	Social unrest	Operation

7 ENVIRONMENTAL MANAGEMENT APPROACH

The compilation of an EMPr for an activity which is likely to result in significant environmental impacts is typically compiled at the culmination of a thorough investigation into the receiving environment and the identification and assessment of likely environmental impacts (i.e. EIA). This EMPr forms part of an EA application process. This EMPr aims to comply with the requirement of Appendix 4 of the EIA Regulations, 2014. These requirements are systematically addressed in the subsequent sections of this report. The primary objectives of the EMPr are as follows:

- To promote sustainability and describe an action programme to mitigate negative impacts as far as possible;
- To be a practical document that sets out both the goals and actions required in mitigation. Though the term "mitigation" can be broad in definition, it means in this context to "allay, moderate, palliate, temper or intensify." Mitigation of a negative impact means that its effect is reduced. Mitigation of a positive impact means that its effect is increased or optimised; and
- To indicate responsibilities for the implementation of these action items within the EMPr.

This EMPr shall be deemed to have contractual standing on the basis that its contents and specifically objectives are a detailed expansion of the environmental risks and consequent requirements of the EA (if, and when issued). Where relevant the Applicant is responsible for delegating responsibility for compliance to designated parties (internal or external). Such delegation must be legally binding to the extent relevant.

The objectives and targets in this EMPr are further guided by the NEMA, and specifically by the EIA Regulations, 2014. Thus, the underlying principles of sustainable development are the ultimate objectives and target of this report. The EMPr has included measures to ensure the development activity complies with the following principles, as instilled in the NEMA, amongst others:

i. That the disturbance of ecosystems and loss of biological diversity are minimised and remedied;

0208

ii. That pollution and degradation of the environment are avoided, or, where they cannot be altogether avoided, are minimised and remedied;

iii. That waste is avoided, minimised and reused or recycled where possible and otherwise disposed of in a responsible manner;

iv. That a risk-averse and cautious approach is applied, which considers the limits of current knowledge about the consequences of decisions and actions; and

v. That negative impacts on the environment and on people's environmental rights be anticipated, prevented and remedied.

7.1 Environmental Management Principles

NEMA establishes a general framework for environmental law, in part by prescribing national environmental management principles that must be applied when making decisions that may have a significant impact on the environment. These principles are briefly summarised below:

7.1.1 Holistic Principle

The Holistic principle, as defined by NEMA (Section 2(4) (b)) requires that environmental management must be integrated, acknowledging that all elements of the environment are linked and inter-related and it must take into account the effect of decisions on all aspects of the environment and all people in the environment by pursuing the selection of the best practicable environmental option (defined below in Section 7.1.2). Holistic evaluation does not mean that a project must be looked at as a whole. It rather means that it must be accepted that there is an all-inclusive whole into which a project is introduced. If the indications are that the project could have major adverse effects, the project must be reconsidered and where appropriate, re-planned or relocated to avoid an adverse impact or to ensure a beneficial impact.

7.1.2 Best Practicable Environmental Option

When it is necessary to undertake any action with environmental impacts, the different options that could be considered for the purpose must be identified and defined. The Best Practicable Environmental Option (BPEO) is defined in NEMA as "the option that provides the most benefit or causes the least damage to the environment as a whole, at a cost acceptable to society, in the long term as well as in the short term." Other guidelines typically used for environmental management in terms of other legislation include: BPM which is the Best Practicable Means and BAT which is the Best Available Technology.

7.1.3 Sustainable Development

The concept of sustainable development was introduced in the 1980's with the aim to ensure that the use of natural resources is such that our present needs are provided without compromising the ability of future generations to meet their own needs. The constitution of South Africa is built around the fact that everyone has the right to have the environment protected through reasonable legislative and other measures that secure ecologically sustainable development. The National Environmental Principles included in the NEMA require development to be socially, environmentally and economically sustainable.

7.1.4 Preventative Principles

The preventative principle is fundamental to sustainable development and requires that the disturbance to ecosystems and the pollution, degradation of the environment and negative impacts on the environment be avoided, or, where they cannot be altogether avoided, are minimised and remedied.

7.1.5 The Precautionary Principle

The precautionary principle requires that where there is uncertainty, based on available information, that an impact will be harmful to the environment, it is assumed, as a matter of precaution, that the said impact will be harmful to the environment until such time that it can be proven otherwise. The precautionary principle requires that decisions by the private sector, governments, institutions and individuals need to allow for and recognise conditions of uncertainty, particularly with respect to the possible environmental consequences of those

5608

decisions. In South Africa, the DWS (then DWAF) adopted a BPEO guideline in 1991 for water quality management and in 1994 in the Minimum Requirements document for waste management.

In terms of DWAF Minimum Requirements for the Handling and Disposal of Hazardous Waste, 1994, the precautionary principle is defined as, "Where a risk is unknown; the assumption of the worst-case situation and the making of provision for such a situation." Here the precautionary principle assumes that a waste or an identified contaminant of a waste is "both highly hazardous and toxic until proven otherwise."

In the context of the EIA process in South Africa, the precautionary principle also translates to a requirement to provide sound, scientifically based, information that is sufficient to provide the decision-making authority with reasonable grounds to understand the potential impacts on the environment, the extent thereof and how impacts could be mitigated. If such information is not adequate for this purpose, the relevant authority cannot be satisfied as is required and then the authority should require that further information be collected and provided.

7.1.6 Duty of Care and Cradle to Grave Principle

In terms of the NEMA Section 28, "Every person who causes, has caused or may cause significant pollution or degradation of the environment must take reasonable measures to prevent such pollution or degradation from occurring, continuing or recurring, or, in so far as such harm to the environment is authorised by law or cannot reasonably be avoided or stopped, to minimise and rectify such pollution or degradation of the environment."

By way of example, the principle of "duty of care" in terms of waste management emphasises the responsibility to make sure that waste is correctly stored and correctly transported, as it passes through the chain of custody to final point of disposal. This means that waste must always be stored safely and securely. The company removing and disposing of waste also holds the responsibility to hold the relevant licenses, and that waste is transported alongside the necessary paperwork.

"Cradle to Grave" refers to the responsibility a company takes for the entire life cycle of a product, service or program, from design to disposal or termination. In terms of the DWAF Minimum Requirements for the Handling and Disposal of Hazardous Waste, 1994, "any person who generates, transports, treats or disposes of waste must ensure that there is no unauthorised transfer or escape of waste from his control. Such a person must retain documentation describing both the waste and any related transactions. In this way, he retains responsibility for the waste generated or handled." This places responsibility for a waste on the Generator and is supported by the "Cradle to Grave" principle, according to which a "manifest" accompanies each load of Hazardous Waste until it is responsibly and legally disposed. This manifest is transferred from one transporter to the next along with the load, should more than one transporter be involved. Once the waste is properly disposed of at a suitable, permitted facility, a copy of the manifest must be returned to the point of origin." Duty of Care offers one strategy to implement sustainable development.

7.1.7 Polluter Pays Principle

The "polluter pays principle" holds that the person or organisation causing pollution is liable for any costs involved in cleaning it up or rehabilitating its effects. It is noted that the polluter will not always necessarily be the generator, as it is possible for responsibility for the safe handling, treatment or disposal of waste to pass from one competent contracting party to another. The polluter may therefore not be the generator but could be a disposal site operator or a transporter. Through the 'duty of care' principle, however, the generator will always be one of the parties held accountable for the pollution caused by the waste. Accordingly, the generator must be able to prove that the transferral of management of the waste was a responsible action. The polluter pays principle according to NEMA dictates that "the cost of remedying pollution, environmental degradation and consequent adverse effects and of preventing, controlling or minimising further pollution, environmental damage or adverse health effects must be paid for by those responsible for harming the environment."

7.2 Duty of Care Responsibilities

Section 28 of the NEMA makes provision for duty of care, and remediation of environmental damage. The binding principles are described below:

5 of 8

1. Every person who causes, has caused or may cause significant pollution or degradation of the environment must take reasonable measures to prevent such pollution or degradation from occurring, continuing or recurring, or, in so far as such harm to the environment is authorised by law or cannot reasonably be avoided or stopped, to minimise and rectify such pollution or degradation of the environment.

   (1A) Subsection (1) also applies to a significant pollution or degradation that-

   a) occurred before the commencement of this Act;

   b) arises or is likely to arise at a different time from the actual activity that caused the contamination; or

   c) arises through an act or activity of a person that results in a change to pre-existing contamination.

2. Without limiting the generality of the duty in subsection (1), the persons on whom subsection (1) imposes an obligation to take reasonable measures, include an owner of land or premises, a person in control of land or premises or a person who has a right to use the land or premises on which or in which-

   a) any activity or process is or was performed or undertaken; or

   b) any other situation exists, which causes, has caused or is likely to cause significant pollution or degradation of the environment.

3. The measures required in terms of subsection (1) may include measures to-

   a) investigate, assess and evaluate the impact on the environment;

   b) inform and educate employees about the environmental risks of their work and the manner in which their tasks must be performed in order to avoid causing significant pollution or degradation of the environment;

   c) cease, modify or control any act, activity or process causing the pollution or degradation;

   d) contain or prevent the movement of pollutants or the cause of degradation;

   e) eliminate any source of the pollution or degradation; or

   f) remedy the effects of the pollution or degradation.

7.3 Failure to Comply with Environmental Considerations

Within the provisions of the relevant environmental legislation, there are a number of penalties for non-compliance or offences. Below a few extracts are presented for information purposes, however these must not be read in isolation and the reader is reminded that there are other Acts, or sections of Acts, that may be applicable to the relevant project:

- NEMA Section 49B(1): A person convicted of an offence in terms of section 49A(1)(a), (b), (c), (d), (e), (f) or (g) is liable to a fine not exceeding R10 million or to imprisonment for a period not exceeding 10 years, or to both such fine or such imprisonment- this includes commencing with a listed activity without an EA or the non-compliance with conditions of any EA and associated EMPr;
- NEMA Section 49B(2): A person convicted of an offence in terms of section 49A(1)(i), (j) or (k) is liable to a fine not exceeding R5 million or to imprisonment for a period not exceeding 5 years, and in the case of a second or subsequent conviction to a fine not exceeding R10 million or to imprisonment for a period not exceeding 10 years, and in both instances to both such fine and such imprisonment;
- NEMA Section 49B(3): A person convicted of an offence in terms of section 49A(1)(h), (l), (m), (n), (o) or (p) is liable to a fine or to imprisonment for a period not exceeding one year, or to both a fine and such imprisonment;
- NWA Section 151 (1c): No person may fail to comply with any condition attached to a permitted water use under this Act;

1623

- NWA Section 151 (2): Any person who contravenes any provision of subsection (1) is guilty of an offence and liable, on the first conviction, to a fine or imprisonment for a period not exceeding five years, or to both a fine and such imprisonment and, in the case of a second or subsequent conviction, to a fine or imprisonment for a period not exceeding ten years or to both a fine and such imprisonment;
- NEM:BA Section 102 (1): A person convicted of an offence in terms of section 101 is liable to a fine not exceeding R10 million, or an imprisonment for a period not exceeding ten years, or to both such a fine and such imprisonment;
- NEM:WA Section 68 (1): A person convicted of an offence referred to in section 67(1)(b), (c), (d), (e), (f), (i), (j), (k) or (l) or section 67(2)(a), (b), (c), (d) or (e) is liable to a fine not exceeding R5 000 000 or to imprisonment for a period not exceeding five years, or to both a fine and such imprisonment, in addition to any other penalty or award that may be imposed or made in terms of the National Environmental Management Act;
- NEM:WA Section 68 (2): A person convicted of an offence referred to in section 67(1)(b), (c), (d), (e), (f), (i), (j), (k) or (l) or section 67(2)(a), (b), (c), (d) or (e) is liable to a fine not exceeding R5 000 000 or to imprisonment for a period not exceeding five years, or to both a fine and such imprisonment, in addition to any other penalty or award that may be imposed or made in terms of the National Environmental Management Act;
- NEM:WA Section 68 (3): Any person convicted of an offence referred to in section 67(1)(m) is liable to a fine or to imprisonment for a period not exceeding six months or to both a fine and such imprisonment;
- NEM:WA Section 68 (4): A person who is convicted of an offence in terms of this Act and who persists after conviction in the act or omission that constituted the offence commits a continuing offence and is liable on conviction to a fine not exceeding R1 000 or to imprisonment for a period not exceeding 20 days, or to both such fine and such imprisonment, in respect of each day that person persists with that act or omission;

It is recommended that a procedure for non-compliances (i.e. incentives or disincentives for conformance and non-conformance with the EMPr requirements) must be employed to ensure that the EMPr is adequately implemented. The system to be used must be determined before the project commences, included in the tender documents and contracts, and made clear to all project workers. The system may include that the independent Environmental Control Officer (ECO) can be authorized to impose spot fines on the Contractor and/or his subcontractors for any of the defined transgressions. Such fines should be issued in addition to any remedial costs incurred as a result of non-compliance with the environmental specifications and or legal obligations.

8 ROLES AND RESPONSIBILITIES

The applicant will be responsible for ensuring overall compliance with the provisions of the EMPr. Implementation is the key to the success of the EMPr. In order to ensure that the EMPr and its mitigation measures are implemented, roles and responsibilities need to be clearly defined and documented prior to commencement. This section serves as a guide on which party is normally responsible for certain tasks. Specific roles are designated in the specific environmental management and mitigation requirements in this EMPr.

8.1 The Project Applicant/Proponent

The applicant is the principal party (Proponent) of the project. For the purposes of this project, it is understood that the Applicant role is fulfilled by the TGS. The legal accountability for correct implementation of the relevant requirements of the EA and EMPr falls primarily upon the applicant and must therefore be built into all contractor's contractual agreements. The applicant's role typically includes:

- Provide for all necessary supervision during the execution of the project including appointment of key personnel to act on his/her behalf during the project (e.g.: Project Manager). The key personnel will be tasked with ensuring that the various contractors/developers comply with the necessary provisions of the EA and EMPr;

3628

- Ensure that the various contractors and applicable sub-contractors appoint a suitably qualified, competent Environmental Officer (EO) that will be responsible for among others, ensuring daily compliance with the EMPr and EA throughout the execution of the relevant project components;
- Appoint a suitably qualified, competent independent Environmental Control Officer (ECO) who will undertake periodic audits on the various contractors works;
- Appoint an independent and suitably qualified MMO to monitor marine fauna for the duration of the survey;
- Appoint an independent and suitably qualified PAM operator to monitor marine fauna for the duration of the survey;
- Appoint a suitably qualified FLO to facilitate communications between the seismic and fishing vessels for the duration of the survey;
- Notify the relevant competent authority of changes in the development resulting in significant environmental impacts;
- Assess the various contractor's environmental performance during the survey, in consultation with the ECO;
- Ensure compliance with regulations;
- To implement the projects as per the approved project plan;
- To ensure that implementation is conducted in an environmentally acceptable manner;
- To inform and educate all employees about the environmental risks associated with the different activities that should be avoided during the survey process and lessen significant impacts to the environment;
- Ensure MMOs and PAM operators are briefed on the area-specific sensitivities and on the seismic survey planning (including roles and responsibilities, and lines of communication); and
- Seabird, turtle and marine mammal incidence data and seismic source output data arising from surveys should be made available on request to the Marine Mammal Institute, DFFE, and the Petroleum Agency South Africa for analyses of survey impacts in local waters. Therefore, ultimately, the Applicant is responsible for the development and implementation of the EMPr and, where relevant, ensuring that the conditions in the EA are satisfied. Where survey activities are contracted out (e.g. to Contractors and Subcontractors), the liability associated with non-compliance still rests with the Applicant (unless otherwise agreed upon between the authorities, the Applicant and the contracting parties). The Applicant (and not the Contractor) is therefore responsible for liaising directly with the relevant authorities with respect to the preparation and implementation of the EMPr and meeting authorisation conditions.

8.2 The Project Manager

During the development, it is envisaged that there may be a number of contractors and sub-contractors undertaking various activities on the project. The Project Manager would oversee all contractors and sub-contractors from a project management point of view. The roles of the Project Manager typically include the following:

- The Project Manager acts on behalf of the Applicant regarding the administration of contracts to sub-contractors, etc.;
- Provides and/or approves scheduling, aspects of co-ordination and estimating,
- Ensures implementation of the project plan within cost, time and quality constraints;
- Ensures that implementation of EMPr is executed as planned; and
- Keeps the asset owner informed of progress made during the life cycle of the project.

5428

8.3 The Environmental Control Officer

The ECO is appointed by the Applicant and should be independent from the Applicant and the Contractors. The ECO should have appropriate training and/or experience in the implementation of environmental management specifications. The ECO must preferably have a tertiary qualification in an Environmental Management or appropriate field. The ECO provides feedback to the Project Manager regarding all environmental matters. The ECO's key role is auditing the implementation of the EMPr. For the purposes of implementing the conditions contained herein, the Applicant should appoint the ECO well before the start of survey activities. The ECO is responsible for the auditing function as well as the clarification of environmental conditions contained in this EMPr to anyone working on the site. For the purposes of this project, the role of ECO and MMO can be fulfilled by the same person.

The ECO roles include:

- Recommendations for review and update of the EMPr;
- Liaison between the Applicant, Contractors, authorities and other lead stakeholders on high importance environmental concerns;
- Ensures that correct shape files have been uploaded into the vessel navigation systems to support effective implementation of spatial controls
- Review the site induction training to ensure environmental issues receive adequate attention and important site-specific issues are included;
- Conduct environmental audits of the site/contractors including relevant documentation on a monthly basis;
- Validating the regular site inspection reports, which are to be prepared by the relevant contractor ECO's;
- Maintain a record of all non-conformances and incidents to ensure that measures are put in place to remedy such;
- Maintain a public consultation register in which all complaints are recorded, as well as action taken; and
- Verification that all environmental monitoring programmes (sampling, measuring, recording etc. when specified) are carried out according to protocols and schedules.

It is important to note that where opportunity for interpretation occurs within the conditions of this EMPr, the interpretation of the ECO will take preference.

8.4 Marine Mammal Observer

Independent Marine Mammal Observer (MMO) is required on board at all times; as a minimum sufficient MMOs must be on watch to cover all hours for the pre-acquisition observations and while the acoustic source is active. The duties of the MMO would be to:

- Give effective briefings to crew members, and establish clear lines of communication and procedures for onboard operations;
- Record seismic source activities, including sound levels, "soft-start" procedures and pre-start regimes;
- Observe and record responses of marine fauna to seismic source from optimum vantage points, including seabird, turtle, seal and cetacean incidence and behaviour and any mortality or injuries of marine fauna as a result of the seismic survey. Data captured should include species identification, position (latitude/longitude), distance/bearing from the vessel, swimming speed and direction (if applicable) and any obvious changes in behaviour (e.g. startle responses or changes in surfacing/diving frequencies, breathing patterns) as a result of the seismic activities. Both the identification and the behaviour of the animals must be recorded accurately along with current seismic sound levels. Any attraction of predatory seabirds, large pelagic fish or cetaceans (by mass disorientation or stunning of fish as a result of seismic survey activities) and incidents of feeding behaviour among the hydrophone streamers should also be recorded;

SLR

- Record sightings of any injured or dead protected species (marine mammals, large pelagic fish (e.g. sharks), seabirds and sea turtles) should be recorded, regardless of whether the injury or death was caused by the seismic vessel itself. If the injury or death was caused by a collision with the seismic vessel, the date and location (latitude/longitude) of the strike, and the species identification or a description of the animal should be recorded and included as part of the daily report;
- Record meteorological conditions at the beginning and end of the observation period, and whenever the weather conditions change significantly;
- Request the delay of start-up or temporary termination of the seismic survey or adjusting of seismic source, as appropriate. It is important that MMO decisions on the termination of seismic source is made confidently and expediently and following dialogue between the observers on duty at the time. A log of all termination decisions must be kept (for inclusion in both daily and "close-out" reports);
- Use a recording spreadsheet in order to record all the above observations and decisions; and
- Prepare daily reports of all observations, to be forwarded to the necessary authorities as required, in order to ensure compliance with the mitigation measures.

8.5 Passive Acoustic Monitoring Operator

An independent Passive Acoustic Monitoring (PAM) Operator is required on board at all times, as a minimum at least one must be on watch at all times while the acoustic source is active. The duties of the PAM operator would be to:

- Provide effective regular briefings to crew members, and establish clear lines of communication and procedures for onboard operations;
- Ensure that the hydrophone cable is optimally placed, deployed and tested for acoustic detections of marine mammals;
- ; Confirm that there is no marine mammal activity within 500 m of the seismic source array prior to commencing with the "soft-start" procedures;
- Record species identification, position (latitude/longitude), distance and bearing from the vessel and acoustic source, where possible;
- Record general environmental conditions;
- Record seismic source activities, including sound levels, "soft-start" procedures and pre-start regimes;
- Request the delay of start-up and temporary termination of the seismic survey, as appropriate;

8.6 Fisheries Liaison Officer

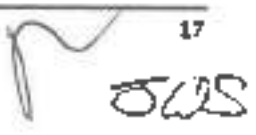
An independent Fisheries Liaison Officer (FLO) must be appointed to undertake the following:

- Facilitate communication with maritime vessels;
- Report daily on vessel activity;
- Respond and advise on action to be taken in the event of encountering fishing gear; and
- Report daily on the survey vessel's potential impacts on marine fauna.

8.7 The Contractor/ Operator

The contractor is usually a third party appointed by the applicant/project manager to undertake the actual survey acquisition. For the purposes of this section, any contractor (regardless of who appointed them) is referred to as the "contractor".

The relevant contractors are answerable to the Project Manager and ECO for all environmental issues associated with the project. Contractor performance will, amongst others, be assessed on health, safety and environmental management criteria. The principal contractor/s, any other contractors and sub-contractors will be required to comply with the provisions contained herein, and accordingly, the EMPr and its provisions must form part of any



contractual arrangements between the applicant and contractors, and contractors and their sub-contractors, etc. The contractor must comply with EMPr and ensure that all his employees and sub-contractors appointed by him/her are familiar with the EMPr. The legal accountability for correct implementation of the relevant requirements of the EA and EMPr must be contractually bound to the appointed contractor.

The Contractors roles include (but not limited to):

- Provide all necessary supervision during the execution of the project;
- Appoint a suitably qualified, competent EO that will be responsible for amongst others, ensuring daily compliance with the EMPr, EA during the acquisition phase;
- Adhere to the instructions of the MMO and PAM operators with regards to seismic source soft start procedures and possible temporary termination of activities if indicated by marine fauna observations;
- To implement the project as per the approved project plan;
- To ensure that implementation is conducted in an environmentally acceptable manner;
- To fulfil all obligations as per the agreed contract; and
- Ensure that the Contractors staff and employees have received the appropriate environmental awareness training prior to commencing survey activities.

8.8 The Contractor/ Operator Environmental Officer

The principal contractor shall appoint an Environmental Officer (EO), who is responsible for implementation of the EMPr. The Contractor must ensure that the Contractor's EO is suitably qualified and competent to perform the necessary tasks and is appointed at a level such that she/he can interact effectively with other Contractors, labourers, the ECO and the public (if necessary). The Contractor's EO ensures that all sub-contractors working under the Contractor and sub-contractors abide by the requirements of the EMPr. The appointment of additional EO's and/or sub-contractors EO's is at the ECO's discretion. The costs related to the implementation of the EMPr will be the responsibility of the relevant Contractor/ sub-contractor.

The Contractor's EO roles will include:

- Preparing activity based Environmental Method Statements where applicable and where required by the ECO;
- Review the contractors safe work procedures/risk assessments/induction training/DSTI's (daily safe task instruction) during the survey and include information relating to the relevant environmental risks and appropriate mitigation measures;
- Support the ECO in monitoring by maintaining a permanent presence on board the survey vessel;
- Establishing and maintaining an environmental incident register;
- Taking required corrective action within specified time frame in respect of non-conformances and environmental incidents;
- Assist in finding environmentally acceptable solutions to problems;
- Attendance at HSE meetings, toolbox talks and induction programmes (where relevant);
- Complete a daily diary with the purpose of recording environmental issues and corrective measures on a daily basis;
- Report any complaints to the ECO to be captured in the Consultation register;
- Liaise with the project teams on issues related to implementation of, and compliance with the EMPr; and
- Ensure adequate and compliant waste management.

5023

8.9 The Authorities

The authorities that should be involved include the Competent Authorities, i.e. PASA and the OMRE. The authorities may be required to perform the following roles:

- Review Monitoring and Audit reports, if required;
- Review whether there is compliance by the Applicant and Contractor with the terms of the EMPr and permit/license conditions. Whenever necessary, the authorities should assist the Applicant in understanding and meeting the specified requirements; and
- The authorities may perform random controls to check compliance. In case of persistent non-compliance, the Applicant will be required to provide an action plan with corrective measures, and have it approved by the authorities.

9 ENVIRONMENTAL MANAGEMENT SYSTEM

The purpose of this EMPr is to ensure that the environment is properly considered during the design, mobilisation, operations, and completion of the survey activities, and that negative impacts are minimised or prevented, and positive impacts enhanced. At the same time the EMPr should provide a logical extension of the EIA, specialist studies, or any other technical planning and assessment documentation, to ensure that recommendations are implemented, and that the project does not deviate from the environmental profile that formed the basis of the assessment.

9.1 Document Control

A formal document control system should be established. The document control system must provide for the following requirements;

- Documents are approved for adequacy prior to use;
- Review and update documents as necessary and re-approve documents;
- Ensure that changes and the current version status of documents are identified;
- Ensure that relevant versions of applicable documents are available at points of use;
- Ensure that documents remain legible and readily identifiable;
- Ensure that documents of external origin necessary for the EMPr are identified and their distribution controlled; and
- Prevent unintended use of obsolete documents and apply suitable identification to them if they are retained for any purpose.

The responsibility for establishing a suitable document control system rests with the Project Manager.

9.2 Record Keeping

It is essential that an official procedure for control of records be developed to ensure records required to demonstrate conformity to environmental standards are maintained. The Applicant, or the Project Manager (if assigned) is therefore required to develop and maintain a procedure for the identification, storage, protection, retrieval, retention and disposal of records as part of the EMPr. Records must be legible, identifiable and traceable.

9.3 Auditing and Reporting Procedures

Reporting procedures must be developed at the start of the project, for conveying information from the compliance monitoring activities and to ensure that management is able to take rapid corrective action should certain thresholds be exceeded. Different reporting procedures may include:

- Inspections;

1594

- Accidents and emergencies;
- Measuring performance indicators and interpreting and acting on the indicators;
- Records of monitoring activities to test the effectiveness of mitigation measures and impact controls, as well as for compliance auditing purposes; and
- Training programmes and evidence of appropriate levels/amount of skills/capacities created.

All monitoring and auditing must be accompanied by applicable records and evidence (e.g. delivery slips, photographic records, etc.). All reports must be retained and made available for inspection by the ECO, the Applicant and /or the Relevant Competent Authorities. All reports shall be signed by the relevant parties to ensure accountability. The Applicant must use the audit report findings to continually ensure that environmental protection measures are working effectively through a system of self-checking. The EMPr should be viewed as a dynamic document aimed at continual environmental performance improvement.

The following auditing and reporting shall be required throughout the survey:

- Daily Environmental Diary: These reports must be prepared by the contractors' EO and must aim to monitor and report on day-to-day activities so as to ensure compliance with the relevant authorisations, licences and permits, the approved EMPr, and environmental method statements;
- Monthly Compliance Reports (EO): These reports must be prepared by the contractors' EO and must aim to provide a concise monthly performance report, including copies of relevant documents (e.g. waste manifests, incident registers, consultation registers, etc);
- Monthly Audit Reports: The ECO must compile monthly compliance reports (audits) which are to be submitted to the Applicant for review and correction of non-compliance issues. It is the responsibility of the ECO to report any non-compliance, which is not correctly rectified. Depending on the outcome of the authorisation processes it may be a requirement to submit these to the relevant authorities.

9.4 Responding to Non-Compliances

Non-compliance will be identified and managed through the following four key activities including:

- Inspections of the survey vessel and activities related to the survey;
- Monitoring of selected environmental quality variables (where relevant);
- Audits of the survey activities and relevant documentation; and
- Reporting on a monthly basis.

An environmental non-conformance and incident register must be prepared and maintained by the ECO throughout the 3D seismic survey in order to track and monitor environmental concerns, incidents, and non-conformances. The register must include details of date, location (coordinates), description of the NC or incident, applicable environmental commitment/standard, corrective action taken, adequacy of corrective action, date rectified, etc.

Non-compliance with the EMPr or any other environmental legislation, specifications or standards shall be recorded by the ECO in the non-conformance register. This register shall be maintained by the ECO and will be sent to the Applicant and Contractor on a regular basis (monthly), and the Applicant shall ensure that the responsible party takes the necessary corrective actions. Non-conformances may only be closed out in the register by the ECO upon confirmation that adequate corrective action has been taken and/or documented proof provided. The register should be utilised to measure overall environmental performance.

9.5 Environmental Incidences

For the purposes of this project, an environmental incident can be divided into three levels, i.e. major, medium and minor. All Major and Medium environmental incidents shall be recorded in the ECO's non-conformance and incident register. Minor incidents shall be recorded by the contractor, and by the Applicant in their own incident register. Definitions of environmental incidents are provided in Table 4.

JL28

Table 4: Description of incidents and non-conformances for the purpose of the project

Non-Conformance	Any deviation from work standards, practices, procedures, regulations, management system performance etc. that could either directly or indirectly lead to injury or illness, damage to the workplace or oceanic environment, legal transgression or a combination of these.
Major Environmental Incident	An incident or sequel of incidents, whether immediate or delayed, that results or has the potential to result in widespread, long-term, irreversible significant negative impact on the oceanic environment and/or has a high risk of legal liability. A major environmental incident usually results in a significant pollution and may entail risk of public danger. Major environmental incidents usually remain an irreversible impact even with the involvement of long-term external intervention i.e. expertise, best available technology, remedial actions, excessive financial cost etc. Major environmental incidents must be reported to the authorities. The ECO shall make the final decision as to whether a particular incident should be classified as a Major incident.
Medium Environmental Incident	An incident or sequel of incidents, whether immediate or delayed, that results or has the potential to result in widespread or localised, short term, reversible significant negative impact on the oceanic environment and/or has a risk of legal liability. A medium environmental incident may be reported to the authorities, can result in significant pollution or may entail risk of public danger. The impact of medium environmental incidents should be reversible within a short to medium term with or without intervention. The ECO shall make the final decision as to whether a particular incident should be classified as a Medium incident.
Minor Environmental Incident	An incident or sequel of incidents, whether immediate or delayed, where the oceanic environmental impact is negligible immediately after occurrence and/or once-off intervention on the day of occurrence.

The following incident reporting procedures shall apply to this project:

- All environmental incidents shall be reported to Contractor's EO, and the ECO, and shall be recorded in the contractors' respective incident registers;
- The ECO shall record the incident in the non-conformance and incident register and advise on the appropriate measures and timeframes for corrective action;
- An incident report shall be completed by the relevant party responsible for the incident for all medium and major incidents and the report shall be submitted to the Project Manager and ECO within 5 calendar days of the incident;
- The EO shall investigate all incidents and identify any required actions to prevent a recurrence of such incidents; and
- In the event of an emergency incident (unexpected sudden occurrence), including a major emission, fire or explosion leading to serious danger to the public or potentially serious pollution of or detriment to the environment, whether immediate or delayed, the Applicant shall notify the relevant authorities in accordance with Section 30(3) of the NEMA. The Applicant shall engage the ECO who shall assess all major incidents and shall advise the Applicant when any such incident must be reported to the authorities as per the above requirement.

9.6 Application of the Mitigation Hierarchy

A key component of the EIA process is to explore practical ways of avoiding and where not possible to reducing potentially significant impacts of the proposed seismic acquisition activities. The mitigation measures put forward are aimed at preventing, minimising or managing significant negative impacts to as low as reasonably practicable (ALARP). The mitigation measures are established through the consideration of legal requirements, project standards, best practice industry standards and specialist inputs.

The mitigation hierarchy, as specified in International Finance Corporation (IFC) Performance Standard 1, is based on a hierarchy of decisions and measures aimed at ensuring that wherever possible potential impacts are mitigated at source rather than mitigated through restoration after the impact has occurred. Any remaining significant residual impacts are then highlighted, and additional actions are proposed. With few exceptions, however, identified impacts were of low significance with very low or zero potential for further mitigation. In such cases the appropriate project Standards will be used and additional best management practices are proposed.

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and Best Available Techniques (BAT), and in compliance with the applicable requirements in the MPRDA regulations.

The operator will ensure that the proposed seismic survey is undertaken in a manner consistent with good international industry practice and in compliance with the applicable requirements in MARPOL 73/78 and industry best practices with regard to waste management

Detailed mitigation measures for seismic surveys in other parts of the world are provided by Weir et al. (2006), Compton et al. (2007) and US Department of Interior (2007). Many of the international guidelines presented in these documents are extremely conservative as they are designed for areas experiencing repeated, high intensity surveys and harbouring particularly sensitive species, or species with high conservation status. A number of countries have more recently updated their guidelines, most of which are based on the JNCC (2010, 2017) recommendations but adapted for specific areas of operation. A review and comparison of these is provided in MaMaCoCo SEA (2015). The guidelines currently applied to seismic surveying in South African waters are those proposed in the Generic EMPR (CCA & CMS 2001). These have been updated as necessary to include salient points from recognised international guidelines, particularly the JNCC (2010, 2017) Guidelines and the 2013 New Zealand Code of Conduct for seismic operations.

10 REVIEW AND REVISION OF THE EMPR

It is important to note that this EMPr is made legally binding on the Applicant through the EA and the approval of the EMPr by the decision-making authority. It is important to consider that the EMPr is a dynamic document which may require such alteration and /or amendment as the project evolves. Conditions under which the EMPr would require revision include:

- Changes in legislation;
- Occurrence of unanticipated impacts or impacts of greater intensity, extent and significance than predicted;
- Inadequate mitigation measures (i.e. where environmental performance does not meet the required level despite the implementation of the mitigation measure);
- Secondary impacts occur as a result of the mitigation measures; and
- Instances where the implementation of the specified management, as a result of changes in circumstances, may become impractical or unreasonable to implement.

The Applicant in consultation with the ECO should be responsible for ensuring that the registration and updating of all relevant EMPr documentation is carried out. It shall be the responsibility of the Applicant, in consultation with the ECO, to ensure that all personnel are performing according to the requirements of the document

control procedure, and to initiate the revision of controlled documents, when required by changes in process or operations.

The ECO must undertake a risk assessment of any proposed changes to the EMPr. This risk assessment must be included in the applicable monthly audit report, and where applicable supported by the necessary proof of public consultation. It is important to note that if alterations and/or amendments are required these may only be affected with written approval from the competent authority and in accordance with the relevant legal processes.

11 ENVIRONMENTAL AWARENESS PLAN AND TRAINING

Training and environmental awareness is an integral part of a complete EMPr. The overall aim of the training will be to ensure that all site staff are informed of their relevant requirements and obligations pertaining to the relevant authorisations, licences, permits and the approved EMPr and protection of the environment.

The applicant and contractor must ensure that all relevant employees are trained and capable of carrying out their duties in an environmentally responsible and compliant manner and are capable of complying with the relevant environmental requirements. To obtain buy-in from staff, individual employees need to be involved in:

- Identifying the relevant risk;
- Understanding the nature of risks;
- Devising risk controls; and
- Given incentive to implement the controls in terms of legal obligations.

The Applicant shall ensure that adequate environmental training takes place. All employees shall have been given an induction presentation on environmental awareness. Where possible, the presentation needs to be conducted in the language of the employees. All training must be formally recorded, and attendance registers retained. The environmental training should, as a minimum, include the following:

- General background and definition of the oceanic environment;
- The importance of compliance with all environmental policies;
- The environmental impacts, actual or potential, of their work activities;
- Compliance with mitigation measures proposed for sensitive marine fauna;
- Their roles and responsibilities in achieving compliance with the environmental policy and procedures and with the requirement of the applicant's environmental management systems, including emergency preparedness and response requirements;
- The potential consequences (legal and/or other) of departure from specified operating procedures including fines (where applicable);
- The mitigation measures required to be implemented when carrying out their work activities; and
- All operational risks must be identified, and processes established to mitigate such risk, proactively. Thus, the applicant needs to inform the employees of any environmental risks that may result from their work, and how these risks must be dealt with in order to avoid pollution and/or degradation of the oceanic environment.

The specific requirements for environmental training during the survey include:

- Environmental Induction Training: All workers must receive induction training which shall be presented by the Contractors HSE Manager Representatives. The induction training must include an environmental management component which will be prepared by the Contractor's EO and presented where possible by the Contractor's EO. The training material must include general environmental awareness with an overview of the approved EMPr and applicable authorisations, licences and permits. Health and safety expectations including communication and reporting to key personnel, including incidents and during emergencies, should also be outlined. The Induction Training Material must be reviewed and approved by the ECO;

- Weekly Environmental Toolbox Talks will be prepared by the Contractor's EO to cover a range of environmental topics and must be presented to relevant staff during applicable times during the seismic survey process (e.g. at the start of a day or activity). The aim of these toolbox talks will be to inform employees of general environmental requirements pertaining to specific activities, as well as specific EMPr and EA requirements and obligations. The ECO shall review environmental toolbox talks on a periodic basis to ensure the material is relevant and appropriate;
- Informal training of all seismic survey staff is also required on an on-going basis through informal discussions, on-site supervision and through facilitation of day-to-day activities. Such training must be given or otherwise facilitated by the Contractor's EO; and
- The Contractor's EO must review all safe work procedures/risk assessments/DSTI's (daily safe task instruction) from the safety department and include the relevant environmental risks and appropriate mitigation measures where necessary. Since the above procedures are specific to the applicable activity being undertaken, the inclusion of environmental measures aims to ensure each activity is undertaken in an environmentally responsible manner.

12 EMERGENCY RESPONSE PLAN

The Applicant must identify potential emergencies and develop procedures for preventing and responding to them. There are several options for dealing with high priority impacts and risks, as the paradigm has two components, probability and consequence. The design of control measures rests on understanding the cause and effect. Best practise is to intervene with the ultimate factors where feasible, rather than treat the outcomes. Emergency response therefore has the option of reducing probability or reducing the consequence while reducing the probability is the preferred option. Below are some common emergency preparedness approaches:

- Threat consequence if a risk eventuates, when the risk becomes an issue;
- Combine reducing the probability and treating the consequence;
- Offset environmental losses by investing in other assets;
- Not manage some of the risks because there are too many; and
- Make provision to manage residual impacts or issues that arise because of shortcomings in risk identification and rating, avoidance and mitigation or because a rare event has occurred.

Residual impacts are those impacts that despite reducing the probability and consequence might still occur. In these cases, parties will have to be compensated, pollution cleaned up and damage to the environment remediated.

The Applicant shall be required to develop and implement an Emergency Preparedness and Response Plan prior to commencing work. The Applicant must ensure that the Emergency Preparedness and Response Plan makes provision for environmental emergencies, including, but not limited to:

- Fire Prevention;
- Fire Emergency Response;
- Spill prevention;
- Spill Response;
- Accidents to employees; and
- Use of hazardous substances and materials, etc.

The Applicant and Contractor must ensure that lists of all emergency telephone numbers/contact persons (including fire control) are kept up to date and that all numbers and names are posted at relevant locations throughout the seismic survey phase.

12.1 Spill Response Procedure

The Contractor must ensure that all employees, staff and labourers are informed and instructed regarding implementation of spill prevention measures and spill response procedures. In the event of a spill, the following general requirements shall apply, and the detailed spill procedure must cater for these requirements:

- Immediately reporting of spills by all employees and/or visitors to the relevant supervisor and EO (this requirement must be including in induction training);
- Take immediate action to contain or stop the spill where it is safe to do so;
- Contain the spill and prevent its further spread;
- Dispose of any contaminated materials according to appropriate waste disposal procedure. Note. Waste from spills of hazardous materials shall be disposed of as hazardous waste at a suitably licensed onshore waste disposal facility;
- The Contractor's EO shall record details of the spill in their respective incident registers;
- Photographic evidence shall be obtained of the spill clean-up.

In the case of large spills, the services of a specialist spill response agency shall be required, who shall advise on appropriate clean-up procedures and follow-up monitoring (if required). The incident procedures as defined in Section 9.5 shall also apply.

The Applicant must also, (as per Section 30 of the NEMA) notify the Director-General (DWS, Competent Authority, DEFF), South African Police Services, Provincial Environmental Authority, the Local Municipality, and any persons whose health may be affected of the nature of an incident including:

- Any risks posed to public health, safety and property;
- Toxicity of the substance or by products released by the incident; and
- Any step taken to avoid or minimise the effects of the incident on public health and the environment.

12.2 Measures to Control or Remedy any Causes of Pollution or Degradation

The broad measures to control or remedy any causes of pollution or environmental degradation as a result of the proposed activities taking place on the project are provided below:

- Ensure that the environmentally sensitive areas are adequately understood by the ship's Captain throughout the survey;
- Contain potential pollutants and contaminants (where possible) at source;
- Handling of potential pollutants and contaminants (where possible) must be conducted in controlled areas;
- Ensure the timeous clean-up of any spills;
- Implement a waste management system for all waste streams present; and
- Investigate any third-party claims of pollution or contamination as a result of the project activities.

13 MANAGEMENT AND MITIGATION

Table 5: Technical or Management Options

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
13.1	**Legal Compliance**						
A	• The Applicant shall identify and comply with all relevant national, provincial and local legislation, including associated regulations and bylaws and shall establish and maintain procedures to keep track of, document and ensure compliance with environmental legislative changes.	Planning Operation	Prior to operation and ongoing	Applicant	ECO (Monthly)	Ensure compliance with relevant legislation.	Up to date legal register. (Legal register) (ECO Monthly Audit)
B	• Should there be changes in legislation and/or regulations the Applicant shall take the necessary actions to incorporate such changes and to pass these requirements on to the Contractors.	Planning Operation	Prior to operation and ongoing	Applicant ECO	ECO (Monthly)	Ensure compliance with relevant legislation / Confirmation that requirements in terms of updated legislation are passed onto the contractors.	(Contractor contractual agreements) (ECO Monthly Audit)
C	• Should surveys run simultaneously, it would be required to amend the EMPr, which would be subject to further assessment and consultation.						
13.2	**Scheduling**						
A	Based on the findings of the Acoustics, Marine Ecology and Fisheries recommendations, it is recommended that the survey window of January – May be utilized in order to: • Avoid sensitive areas and periods for some marine fauna: Movement of migratory cetaceans (particularly baleen whales) from their southern feeding grounds into low latitude waters (June/July and late October/November), and their aggregation on the summer feeding grounds between St Helena Bay and Dassen Island from late October to late December and ensure that migration paths are not blocked by seismic operations; • Avoid periods of peak fishing activity during June and July in order to reduce the probability of disruption to the large pelagic longline fishing sector and tuna pole line fishing sector.	Planning Operation	Prior to operation and ongoing	Applicant ECO	ECO (ongoing)	Limit survey to January – May.	Survey logs and ECO Reports.

1601

Item No.	Technical or Management Option	Phase	Timeframe	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
13.3. Appointment of ECO/MMO/PAM/FLO							
A	• The Applicant shall appoint a suitably qualified ECO who shall be independent from the Applicant and the Contractor. The ECO must preferably have a tertiary qualification in Environmental Management or appropriate environmental science field. The ECO should have appropriate qualification and experience in the implementation of environmental management specifications. For the purposes of implementing the conditions contained in this EMPr. The Applicant shall provide the ECO with the necessary support to ensure that the environmental aspects relating to the development is adhered to. The appointment of the ECO shall remain in force until all obligations of this EMPr have been met (e.g. including any relevant rehabilitation phase)	Planning Operation	Prior to operation	Applicant	Applicant (once off prior to operations)	Appoint ECO to ensure monitoring of successful implementation of the EMPr.	Confirmation that ECO has been appointed and is suitably qualified to perform the duties contained in this EMPr. (ECO appointment and CV)
B	• Qualified, independent MMOs are required on board at all times; as a minimum sufficient MMOs must be on watch to cover all hours while the acoustic source is active.	Planning Operation	Prior to operation	Applicant	Applicant (once off prior to operations)	Appoint MMO to ensure monitoring of successful implementation of the EMPr.	Confirmation that MMO has been appointed and is suitably qualified to perform the duties contained in this EMPr. (MMO appointment and CV)
C	• Qualified, independent PAM Operators are required on board at all times, as a minimum one must be on watch while the acoustic source is active.	Planning Operation	Prior to operation	Applicant	Applicant (once off prior to operations)	Appoint PAM to ensure monitoring of successful implementation of the EMPr.	Confirmation that PAM has been appointed and is suitably qualified to perform the duties contained in this EMPr. (PAM appointment and CV)
D	• The Applicant shall appoint an independent FLO who must have experience in the liaising with the fishing operations and communities.	Planning Operation	Prior to operation	Applicant	Applicant (once off prior to operations)	Appoint FLO to ensure monitoring of successful implementation of the EMPr.	Confirmation that FLO has been appointed and is suitably qualified to perform the duties contained in this EMPr. (FLO appointment and CV)
E	• The Applicant is responsible for the maintenance, update and review of the EMPr. The ECO shall include any recommendations for proposed amendments/alterations of the EMPr to the Applicant who shall engage the competent authority, to the extent required, with regards to such changes.	Planning Operation	As required	Applicant ECO	ECO (Monthly) Applicant (as and when necessary)	Ensure EMPr is reviewed and updated where necessary to ensure adequate mitigation for all impacts associated with the project.	Audit results and recommendations (ECO Monthly Audit)

1602

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
13.4 . Appointment of Contractors							
A	• The EMPr must be made binding on the contractor/s and should be included in tender documentation and contracts. The costs related to the implementation of the EMPr during survey activities must be provided for in the contract.	Planning Operation	Prior to operation	Applicant Contractors	ECO (Once-off at the start of individual contractor's work)	Ensure that the contractor is in possession of the EMPr and that they understand their obligations thereto.	Confirmation that contractor has received EMPr, and that EMPr has been made contractually binding. (Contractual agreements) (ECO Monthly Audit)
B	• All contractors and sub-contractors must have a copy of this EMPr on site and should be briefed by the EO with regards to the use and implementation of the EMPr.	Planning - Operation	Prior to Operation and Ongoing	Contractor	ECO (Monthly) Applicant (once off per contractor)	Ensure all contractors are aware of EMPr requirements.	Confirmation that contractors have received training relating to EMPr implementation. (Training records) (ECO Monthly Audit)
C	• The Contractor shall appoint a dedicated Contractor's EO who is suitably qualified to perform the necessary tasks and is appointed at a level such that she/he can interact effectively with other site Contractors, labourers, the ECO and the public. The Contractor's EO shall be appointed prior to the onset of the seismic survey.	Planning	Prior to Operation and Ongoing	Contractor	ECO (Once-off)	Ensure a suitably qualified EO is present on site to oversee day to day activities and ensure successful implementation of EMPr during the seismic survey.	Confirmation that EO has been appointed and is suitably qualified to perform the necessary duties contained in the EMPr. (ECO Monthly Audit)
D	• The Contractor shall ensure that all sub-contractors working under them abide by the requirements of the EMPr through the inclusion of the EMPr and applicable environmental requirements in contractual agreements for all sub-contractors.	Operation	Ongoing	Contractor	EO (Weekly) ECO (Monthly)	Ensure that the contractor implements all the mitigation measures as described in the EMPr.	Signed declaration of understanding by contractors (EO weekly checklist) (ECO Monthly Audit Report)
13.5 Health and Safety							
A	The Applicant through the Project Manager shall ensure: • That reasonable measures are taken to ensure the safety of all site staff; • Provide appropriate Personal Protective Equipment (PPE) where required. • Compliance with the Occupational Health and Safety Act (Act No. 85 of 1993) and associated regulations; • That all accidents and incidents are recorded and reported to the Project Manager and EO/ECO; and • The Applicant and Contractor must ensure that he/she has the contact details of the nearest emergency rooms (hospitals) of both private and public hospitals.	Operation	Ongoing	Project Manager Contractor	Safety Department	Ensure compliance with legal provisions of OHSA.	(safety reports) (safety audits)

1603

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
13.6 Emergency Response / Disaster Management Planning							
A	• Develop and implement an Emergency Preparedness and Response Plan (EPRP) for implementation during the seismic survey. This should be revised periodically as the various phases of the seismic survey work takes place.	Planning Operation	Prior to Operation and Ongoing	Contractor	ECO (Once-off)	Ensure emergency preparedness and response systems in place.	Verification that EPRP is in place. (ECO Audit) (EPRP) (Incident Reports)
13.7 Socio-Economic Considerations							
A	• TGS should develop a community engagement protocol that is based on the Sea Code of Research Ethics. This should be done in consultation with the affected communities. This should include a communication strategy and grievance mechanism.	Planning Operation	Prior to Operation and Ongoing	Applicant/ Project manager	ECO (Monthly)	Ensure that socio-economic considerations are considered and implemented where necessary	Preparation and maintenance of a community engagement protocol. (ECO Monthly Audit), (Consultation register)
	• TGS should contribute to assisting with collaboration on independent research on bear fish species on the West Coast such as snoek respond to seismic surveying. TGS will further contact relevant scientific research institutions to offer the potential of collaborating in independent on-water research during the survey. It is recommended that the Department of Agriculture, Forestry and Fisheries, Oceans & Coasts, Research component be contacted for possible collaboration on further research on the impact of seismic surveys on the marine ecosystem.	Planning Operation	Prior to Operation and Ongoing	Applicant/ Project manager	ECO (Monthly)	Ensure that socio-economic considerations are considered and implemented where necessary	Proof of consultation and attempts at collaboration
C	• Consult with communities on potential ways in which to make a positive contribution to the communities. • TGS should investigate opportunities for the employment of people from local communities and skills development.	Planning Operation	Prior to Operation and Ongoing	Applicant/ Project manager	ECO (Monthly)	Ensure that socio-economic considerations are considered and implemented where necessary	Consultation Register (ECO Monthly Audit)
D	• A representative from TGS should consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in future. This will assist with adjusting the relationship between TGS and the traditional communities. Given the socio-political environment, opposition to the project and associated non-technical risks, further meaningful	Planning Operation	Prior to Operation and Ongoing	Applicant/ Project manager	ECO (Monthly)	Ensure that socio-economic considerations are considered and implemented where necessary	Consultation Register and workshops (ECO Monthly Audit)

1604

Item No.	Technical or Management Option	Phase	Timeframe	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
	engagement with the leadership and communities are critical from a social perspective. • TGS should also initiate discussions in their industry. The seismic survey industry should reassess their position and social licence to operate as an industry in a South African context and conduct a strategic environmental assessment of the impact of the industry and embark on an awareness raising and education campaign. Having meetings will not be sufficient. Participatory processes and workshops where communities can engage in experiential learning should be considered. If the seismic survey industry fails to address the community's need for education and cooperation it will result in significant delays and increase the risk for social unrest.						
F	• TGS should approach the authorities and enter into conversation regarding a strategic impact assessment for the area that should be contributed to by all the prospecting/ exploration companies involved.	Planning Operation	Prior to Operation and Ongoing	Applicant/ Project manager	ECO (Monthly)	Ensure that socio-economic considerations are considered and implemented where necessary	Proof of consultation with authorities
	13.8 Heritage/ Palaeontological Features						
A	• Re-assess post-project the potential effects on the identified communities and their intangible cultural heritage. This will require consideration of the socio-economic baseline developed during the environmental impact process against quantified economic damage and losses and human development impacts in a follow-up socio-economic assessment. It will enable the heritage specialist to evaluate the link between the socio-economic changes induced by the proposed project as it relates to changes in the intangible cultural heritage practices of the communities. • Based on the outcomes, provide resources and support for communities to develop and undertake safeguarding measures or plans to enhance the mitigation capacity of their intangible cultural heritage by fostering dialogue, mutual understanding and reconciliation between and within communities. • 3D seismic survey have the potential to locate wrecks on the surface, and sometimes below sediments on the ocean	Planning Closure	During Operation	Applicant/ Project manager in consultation with specialist	ECO – once off	Re-assess post project, the effects on the identified communities and their intangible cultural heritage Enhance mitigation capacity of intangible cultural heritage	Safeguarding measures or plans in place post survey.

1605

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
	floor. Any shipwrecks or pieces thereof noted during the survey must be shared with the SAHRA MPOH Unit for inclusion into the national database. These could then be identified and be incorporated into the EMPr.						
	13.9 Air Quality						
A	• Maintain all diesel motors and generators in good working order. Properly tune and maintain all engines, motors, generators and all auxiliary power to contain the minimum of soot and unburned diesel.	Operation	Ongoing	Applicant & Contractor	ECO (Weekly)	Ensure that no excessive air quality impacts are perceived	Visual confirmation of compliance with EMPr conditions. (EO weekly checklist) (ECO Monthly Audit)
	13.10 Noise Nuisance						
A	In the unlikely event that aircraft are utilised for crew changes or medivac: • Plan support aircraft flight path to avoid sensitive and protected areas and ensure no flying occurs over coastal seal colonies and seabird nesting areas • Avoid excessive low-altitude coastal flights by ensuring that the flight path is perpendicular to the coast, as far as possible. • Brief all pilots on the ecological risks associated with flying at a low level along the coast or above marine mammals.	Planning Operation	Prior to Operation and Ongoing	Applicant Contractor	EO (Weekly) ECO (Monthly)	Ensure that noise levels are controlled within acceptable limits. No complaints relating to noise.	Confirmation that noise levels are within acceptable limits and relevant notifications undertaken. (EO weekly checklist) (ECO Monthly Audit) (Consultation register)
	13.11 Acoustic Impacts of Seismic Surveys on Marine Fauna						
A	• All initiation of seismic source acquisition be carried out as "soft-starts" of at least 20 minutes duration.	Operation	During Operation	Contractor	EO (Weekly) ECO (Monthly)	Utilisation of soft starts at initiation.	Confirmation soft starts at initiation. (EO weekly checklist) (ECO Monthly Audit)
B	• Implement a dedicated MMO and PAM pre-acquisition watch of at least 60 minutes (to accommodate deep-diving species in water depths greater than 200 m).	Operation	During Operation	Contractor	EO (Weekly) ECO (Monthly)	Utilisation of soft starts at initiation.	Confirmation soft starts at initiation. (EO weekly checklist) (ECO Monthly Audit)
C	• Implement a "soft-start" procedure of a minimum of 20 minutes' duration on initiation of the seismic source if: o During all hours it is confirmed visually by the MMO during the pre-acquisition watch (60 minutes) that there are no penguins or feeding aggregations of diving seabirds, shoaling large pelagic fish, turtles, seals or cetaceans within 500 m of the seismic	Operation	During Operation	Contractor	EO (Weekly) ECO (Monthly)	Utilisation of soft starts at initiation. 	13.12 Line Turns and Breaks in Acquisition						
A	• If line changes are expected to take less than 40 minutes, seismic acquisition can continue during the line change if: ○ The power is reduced to 200 cubic inches (or as close as is practically feasible) at standard pressure. Seismic source volumes of less than 200 cubic inches can continue to discharge at their operational volume and pressure; ○ The Seismic Pulse Interval (SPI) is increased to provide a longer duration between pulses, with the SPI not to exceed 5 minutes; and ○ The power is increased, and the SPI is decreased in uniform stages during the final 20 minutes of the line change (or geophone repositioning), prior to data collection re-commencing (i.e. a form of mini soft start). ○ Normal MMO and PAM observations continue during this period when reduced power seismic source is active.	Operation	During Operation	Contractor	EO (Weekly) ECO (Monthly)	Utilisation of soft starts.	Confirmation soft starts (EO weekly checklist) (ECO Monthly Audit)
B	• If after breaks in seismic acquisition, the seismic source can be restarted within 5 minutes, no soft-start is required, and acquisition can recommence at the same power level provided no marine mammals have been observed or detected in the mitigation zone during the break-down period. • For all breaks in seismic source of longer than 5 minutes, but less than 20 minutes, implement a "soft-start" of similar duration, assuming there is continuous observation by the MMO and PAM operator during the break. • For all breaks in seismic source of 20 minutes or longer, implement a 60-minute pre-acquisition watch and 20-minute "soft-start" procedure prior to the survey operation continuing. • For planned breaks, ensure that there is good communication between the seismic contractor and MMO and PAM operators in order for all parties to be aware of these breaks and that early commencement of pre-watch periods can be implemented to limit delays.	Operation	During Operation	Contractor	EO (Weekly) ECO (Monthly)	Utilisation of soft starts.	Confirmation soft starts (EO weekly checklist) (ECO Monthly Audit)
C	• If line changes are expected to take longer than 40 minutes:	Operation	During Operation	Contractor	EO (Weekly)	Utilisation of soft starts.	Confirmation soft starts (EO weekly checklist)

1610

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
	• Terminate seismic source at the end of the survey line and implement a pre-acquisition search (40 minutes) and "soft-start" procedure (20 minutes) when approaching the next survey line. • If line turn is shorter than 60 minutes (i.e. shorter than a 40-minute pre-acquisition watch and 20-minute "soft-start" combined), the pre-acquisition watch can commence before the end of the previous survey line.				ECO (Monthly)		(ECO Monthly Audit)
13.13 Shut-downs							
A	• Seismic source should be terminated on observation of penguins or feeding aggregations of diving seabirds, turtles, slow swimming large pelagic fish (including whale sharks, basking sharks, and manta rays), seals and cetaceans within the 500 m mitigation zone. If PAM detects the presence of very high frequency cetaceans (Heaviside's dolphins, pygmy sperm whale and dwarf sperm whale) within 1 000 m of the sound source, seismic source should be terminated. • Terminate source for cetaceans until such time as there has been a 30-minute delay from the time the animal was last sighted within the mitigation zone before the commencement of the normal soft start procedure. For specific species of turtles, penguins diving seabirds and slow swimming large pelagic fish, diving seabirds, terminate source until such time as the animals are outside of the 500 m mitigation zone (seismic "pause", no soft-start required)	Operation	During Operation	Contractor MMO PAM Operator	MMO (ongoing) ECO (Monthly)	Visual scanning and termination of activities.	Confirmation recording of visual scanning, Termination of activities. (MMO Reports) (ECO Monthly Audit)
B	• Seismic source should be terminated on observation of any obvious mortality or injuries to cetaceans, turtles, seals or mass mortalities of invertebrate and fish species (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and roackerel) as a direct result of the survey. Such mortalities would be of particular concern where a) commercially important species are involved, or b) mortality events attract higher order predator and scavenger species into the seismic area during the survey, that subjecting them to acoustic impulses.	Operation	During Operation	Contractor MMO PAM Operator	MMO (ongoing) ECO (Monthly)	Visual scanning and termination of activities.	Confirmation recording of visual scanning, Termination of activities. (MMO Reports) (ECO Monthly Audit)

1611

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Targets	Performance Indicators (Monitoring Tool)
C	• Seismic source should also be terminated when observer changes to turtle, seal or cetacean behaviours are observed from the survey vessel, or turtles and cetaceans (not seals) are observed within 500 m of operating seismic sources or appear to be approaching active seismic sources (particularly if the MMO has lost sight of the approaching animal prior to it entering the mitigation zone). The rationale for this is that animals at close distances (i.e. where physiological injury may occur) may be suffering from reduced hearing as a result of seismic sounds, that frequencies of seismic sound energy lies below best hearing frequencies (certain toothed cetaceans and seals), or that animals have become trapped within the area filled with sound through diving behaviour.	Operation	During Operation	Contractor MMO PAM Operator	MMO (ongoing) ECO (Monthly)	Visual scanning and termination of activities.	Confirmation recording of visual scanning, Termination of activities. (MMO Reports) (ECO Monthly Audit)

Survey logs. (MMO Reports) (ECO Monthly Audit)
13.14 Key Equipment							
A	Key Equipment to be used: • All seismic vessels must be fitted with Passive Acoustic Monitoring (PAM) technology, which detects animals through their vocalizations. • The use of PAM 24-hrs a day must be implemented to detect deep diving species. • Ensure the PAM streamer is fitted with at least four hydrophones, of which two are HF and two LF, to allow directional detection of cetaceans. • Ensure the PAM hydrophone streamer is towed in such a way that the interference of vessel noise is minimized. • Ensure spare PAM hydrophone streamers are readily available in the event that PAM breaks down, in order to ensure timeous redeployment. • Define and enforce the use of the lowest practicable seismic source volume for production. Design arrays to maximize downward propagation, minimize horizontal propagation and minimize high frequencies in seismic source pulses.	Planning Mobilization Operation	Mobilization and Operation	Contractor PAM Operator	PAM Operator (ongoing) ECO (Monthly)	Adequate equipment is in place and used as per the requirements and specifications.	Confirmation of PAM Operations (PAM Operator Reports, ECO Reports). Use of lowest volume seismic sources, turtle friendly buoys, operation within approved area, use of solid streamers.

1612

Item No.	Technical or Management Option	Phase	Timeframe	Responsible Party	Monitoring Plan (Frequency)	Target	Performance Indicator (Monitoring Tool)
	• Ensure the ramp-up airgun volumes do not exceed the production volume. • Prevent seismic source use (including seismic source tests) outside of the area of operation (which includes line turns undertaken outside the licence area). • The operator must provide a display screen for the acoustic source operations. 'All' information relating to the activation of the acoustic source and the power output levels must be readily available to support the observers in real time via the display screen and to ensure that operational capacity is not exceeded. • MMOs are to be equipped with night-vod cameras in order to observe mammals at night. • Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'. • Ensure that 'solid' streamers rather than fluid-filled streamers are used to avoid leaks. • Ensure that 'turtle-friendly' tail buoys are used by the survey contractor or that existing tail buoys are fitted with either exclusion or deflector 'turtle guards'. • Ensuring that leads are lifted using the correct lifting procedure and within the maximum lifting capacity of crane system. • Minimize the lifting path between vessels. • Undertake frequent checks to ensure leads and equipment are stored and secured safely on board each vessel. • In the event that equipment is lost during the operational stage, assess safety and metocean conditions before performing any retrieval operations. Establishing a hazards database listing the type of gear left on the seabed and/or in the Reconnaissance Permit Area with the dates of abandonment/loss and locations, and where applicable, the dates of retrieval. Notify SAN Hydrographer of any hazards left on the seabed or floating in the water column, and request that they send out a Notice to Mariners with this information. • Use low toxicity dispersants cautiously and only with the permission of DFFE. • Ensure adequate resources are provided to collect and transport oiled birds to a cleaning station.

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
13.15 PAM Malfunctions							
A	• If the PAM system malfunctions or becomes damaged during night-time operations or periods of low visibility, continue operations for 30 minutes without PAM if no marine mammals were detected by PAM in the mitigation zones in the previous 2 hours, while the PAM operator diagnoses the issue. If after 30 minutes the diagnosis indicates that the PAM gear must be repaired to solve the problem, reduce power to 180 cubic inches. The reduced seismic source may continue for 30 minutes while PAM is being repaired, the last 10-minutes of which is a 20-minute ramp-up to full power (also "soft-start"). If the PAM repair will take longer than 60 minutes, stop surveying until such time as a functional PAM system can be redeployed and tested. • If the PAM system breaks down during daylight hours operations may continue for 20 minutes without PAM while the PAM operator diagnoses the issue. If the diagnosis indicates that the PAM gear could be repaired to solve the problem, operations may continue for an additional 2 hours without PAM monitoring as long as: o No marine mammals were detected solely by PAM in the mitigation zones in the previous 2 hours; o Two MMOs maintain watch at all times during operations when PAM is not operational; o The time and location in which operations began without an active PAM system is recorded.	Operation	Operation	Contractor PAM Operator MMO	PAM Operator (ongoing) ECO (Monthly)	Ceasing activities during PAM Malfunctions. PAM equipment investigation and repair.	Ceasing activities during PAM Malfunctions. PAM equipment investigation and repair. (PAM Operator Reports, ECO Reports).
13.16 Seismic source Testing							
A	For seismic source testing the following should apply: • Maintain a pre-acquisition watch of 60-minutes before any instances of seismic source testing. If only a single lowest power seismic source is tested, the pre-acquisition watch period can be reduced to 30 minutes.	Operation	Operation	Contractor	PAM Operator (ongoing) ECO (Monthly)	Adequate testing is in place and conducted as per the requirements and specifications.	Testing in line with the requirements (PAM Operator Reports, ECO Reports)
B	• Implement a "soft-start" procedure if testing multiple seismic sources. ◇ The "soft-start" should be carried out over a time period proportional to the number of seismic	Operation	Operation	Contractor	PAM Operator (ongoing) ECO	Adequate testing is in place and conducted as per the requirements and specifications.	Testing in line with the requirements (PAM Operator Reports, ECO Reports)

	sources being tested and not exceed 20 minutes; seismic sources should be tested in order of increasing volume; o If testing all seismic sources at the same time, a 20 minute "soft-start" is required; o If testing a single lowest power seismic source a "soft-start" is not required.				(Monthly)		
	13.17 Waste Management						
A	• The discharge of biodegradable wastes from vessels is regulated by MARPOL 73/78 Annex V, which stipulates that: o No disposal to occur within 3 nautical miles (± 5.5 km) of the coast. o Disposal between 3 nautical miles (± 5.5 km) and 12 nautical miles (± 22 km) needs to be comminuted to particle sizes smaller than 25 mm. o Disposal overboard without macerating can occur greater than 12 nautical miles from the coast when the vessel is sailing.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Proper waste management in line with the required EMPr and regulations.	Recording of waste types and quantities (waste register and records)
B	• Discharges of oily water (deck drainage, bilge and mud pit wash residue) to the marine environment are regulated by MARPOL 73/78 Annex I, which stipulates that vessels must have: o A Shipboard Oil Pollution Emergency Plan (SOPEP). o A valid International Oil Pollution Prevention Certificate, as required by vessel size. o Equipment for the control of oil discharge from machinery space bilges and oil fuel tanks, e.g. oil separating/filtering equipment and oil content meter. Oil in water concentration must be less than 15 ppm prior to discharge overboard. o Oil residue holding tanks. o Oil discharge monitoring and control system.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Proper waste management in line with the required EMPr and regulations.	Recording of waste types and quantities (waste register and records)
C	• Sewage and grey water discharges from vessels are regulated by MARPOL 73/78 Annex IV, which specifies the following: o Vessels must have a valid International Sewage Pollution Prevention Certificate.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Proper waste management in line with the required EMPr and regulations.	Recording of waste types and quantities (waste register and records)

1615

Item No.	Technical or Management Option	Phase	Timeframes	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
	◇ Vessels must have an onboard sewage treatment plant providing primary settling, chlorination and dechlorination before discharge of treated effluent. ◇ The discharge depth is variable, depending upon the draught of the seismic vessel / support vessel at the time, but will be in accordance with MARPOL 73/78 Annex IV. ○ Discharge of sewage beyond 12 nm requires no treatment. However, sewage effluent must not produce visible floating solids in, nor cause the discolouration of, the surrounding water. ○ Sewage must be comminuted and disinfected for discharges between 3 nautical miles (± 6 km) and 12 nautical miles (± 22 km) from the coast. This will require an onboard sewage treatment plant or a sewage comminuting and disinfecting system. ○ Disposal of sewage originating from holding tanks must be discharged at a moderate rate while the ship is proceeding on route at a speed not less than 4 knots.						
D	• Sewage will be treated using a marine sanitation device to produce an effluent with: ◇ A biological oxygen demand (BOD) of <25 mg/l (if the treatment plant was installed after 1/1/2010) or <50 mg/l (if installed before that date). ◇ Minimal residual chlorine concentration of 1.0 mg/l. ◇ No visible floating solids or oil and grease.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Proper waste management in line with the required EMPr and regulations.	Recording of waste types and quantities (waste register and records)
E	• The project will also comply with industry best practices with regard to waste management, including the completion of a waste management plan that includes the following: ○ Waste management will follow key principles: Avoidance of Waste Generation, adopting the Waste Management Hierarchy (reduce, reuse, recycle, recover, residue disposal), and use of Best Available Technology (BAT). ○ An inventory will be established of all the potential waste generated, clarifying its classification (hazardous, non-hazardous or inert) and quantity, as well as identifying the adequate treatment and disposal methods.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Proper waste management in line with the required EMPr and regulations.	Recording of waste types and quantities (waste register and records)

1616

Item No.	Technical or Management Option	Phase	Timeframe	Responsible Party	Monitoring Party (Frequency)	Target	Performance Indicators (Monitoring Tool)
	○ Waste collection and temporary storage shall be designed to minimise the risk of escape to the environment (for example by particulates, obliteration, runoff or odours). ○ On-site waste storage should be limited in time and volume. ○ Dedicated, clearly labelled, containers (bins, skips, etc.) will be provided in quantities adapted to anticipated waste streams and removal frequency.						
F	• Avoid the unnecessary discharge of ballast water. • Use filtration procedures during loading in order to avoid the uptake of potentially harmful aquatic organisms, pathogens and sediment that may contain such organisms. • Ensure that routine cleaning of ballast tanks to remove sediments is carried out, where practicable, in mid-ocean or under controlled arrangements in port or dry dock, in accordance with the provisions of the ship's Ballast Water Management Plan. • Ensure all infrastructure (e.g. airguns, streamers, tail buoys etc) that has been used in other regions is thoroughly cleaned prior to deployment.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Proper waste management in line with the required EMPr and regulations.	Recording of waste types and quantities (waste register and records)
	13.18 Vessel and Aircraft Operations						
	• Ensure vessel transit speed between the survey area and port is a maximum of 12 knots (22 km/hr), except in the MPAs where it is reduced further to 10 knots (18 km/hr) as well as when they are present in the vicinity.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Ensure vessel speed limits are adhered to	Confirmation of flights undertaken in accordance with the requirements (ECO Reports, ship logs)
A	In the unlikely event that aircraft are utilised for crew changes or medevac: • Pre-plan flight paths to ensure that no flying occurs over seabird and seal colonies and offshore islands by at least 1 852 m (i.e. 1 nm); • Avoid extensive low-altitude coastal flights by ensuring that the flight path is perpendicular to the coast, as far as possible • The flight path between the onshore logistics base and seismic vessel should be perpendicular to the coast; • Brief all pilots on the ecological risks associated with flying at a low level along the coast or above marine mammals.	Operation	During Operation	Contractor ECO	ECO (ongoing)	Adequate flight planning in line with the requirements of the EMPr and legislation.	Confirmation of flights undertaken in accordance with the requirements (ECO Reports, Flight plans).
B	• The lighting on the seismic vessel and support vessels should be reduced to a minimum compatible with safe	Operation	During Operation	Contractor ECO	ECO (ongoing)	Adequate lighting and vessel planning,	Confirmation of lighting and vessel planning, operation and

	operations whenever and wherever possible. Light sources should, if possible and consistent with safe working practices, be positioned in places where attraction to the surrounding environment can be minimized.
	• Keep disorientated, but otherwise unharmed, seabirds in dark containers for subsequent release during daylight hours. Ringed/banded birds should be reported to the appropriate ringing/banding scheme (details are provided on the ring).
	• Avoid the unnecessary discharge of ballast water.
	• Use filtration procedures during loading in order to avoid the uptake of potentially harmful aquatic organisms, pathogens and sediment that may contain such organisms.
	• Ensure all infrastructure (e.g. arrays, streamers, tail buoys etc.) that has been used in other regions is thoroughly cleaned prior to deployment.
	• Implement a waste management system that addresses all wastes generated at the various sites, shore-based and marine. This should include:
	  ○ Separation of wastes at source.
	  ○ Recycling and re-use of wastes where possible.
	• Treatment of wastes at source (maceration of food wastes, compaction, incineration, treatment of sewage and oily water separation).
	• Implement leak detection and repair programmes for valves, flanges, fittings, stairs, etc.
	• Use a low-toxicity biodegradable detergent for the cleaning of all deck spillages.
	• The vessel operators should keep a constant watch for marine mammals and turtles in the path of the vessel. Keep watch for marine mammals behind the vessel when tension is lost on the towed equipment and either retrieve or regain tension on towed gear as rapidly as possible.
	• In the event that equipment is lost during the operational stage, assess safety and metocean conditions before performing any retrieval operations.
	• Ensure that routine cleaning of ballast tanks to remove sediments is carried out, where practicable, in mid-ocean or under controlled arrangements in port or dry dock, in accordance with the provisions of the ship's Ballast Water Management Plan.
						operation and maintenance in line with the requirements of the EMP and legislation.	maintenance undertaken in accordance with the requirements (ECO Reports, maintenance plans, O&M Manuals).

Appendix 1: EAP Curriculum Vitae

EIMS ENVIRONMENTAL IMPACT MANAGEMENT SERVICES

CURRICULUM VITAE

Name:	Liam Michael Whitlow
Nationality:	South African
Date of Birth:	22 August 1978
Profession:	Environmental Scientist
Professional Qualification/ Training:	BSc Honours Environmental Management; Rand Afrikaans University (now University of Johannesburg), 2000
	Higher Certificate in Project Management; Damelin Business School, 2001.
	ISO 14001 Auditor Training; BVQI, 2003.
	Environmental Monitoring- Fallout Dust Training; Dustwatch, 2014.
	Aquifer Hydraulics and Groundwater Monitoring Certificate Course; North West University, 2014.
	Carbon Footprint Analyst Course; Terra Firma Academy, 2017.
Professional Membership/ Registrations:	Registered Environmental Assessment Practitioner: Number 2019/222 Registered Professional Natural Scientist (SACNASP- #400148/08). Member of Land Rehabilitation Society of Southern Africa (LaRSSA).
Current Employer:	Environmental Impact Management Services (Pty) Ltd.

KEY EXPERIENCE

Liam holds a B. Sc. Hons degree in Environmental Management and has completed an additional B. Sc. honours course in applied limnology. In addition he has completed a higher certificate in Project Management with Damelin Business School and a course on ISO14001 Auditing Principles and Environmental Management Systems Auditor Training. Liam is a registered professional natural scientist with the South African Council for Natural Scientific Professions. Liam's professional experience, gained over more than 17 years, lies mainly with environmental impact assessments including project managing significantly large EIA's in the mining and infrastructure sectors. Liam's other experience includes ISO14001, Site Assessments, Water-use licensing, Environmental monitoring, and Environmental Management Plans. Liam's experience lies mainly within South Africa but he has bene involved in projects in both Lesotho and Botswana.

CAREER SUMMARY

Period: January 2011 - Current	Organisation: EIMS	Position: Director, Senior Environmental Assessment Practitioner

Key Projects/Assignments	Technical Director: Responsible for the technical management of EIMS including the following aspects: • Technical review and direction for complex projects; • Quality control and assurance; • Staff management and performance review; • Client management; and • Marketing and business development. Project Experience: • Transnet Multi-products Pipeline (~650km total length) in Gauteng, Mpumalanga and between Durban and Johannesburg, RSA. Project manager and Environmental Advisor to the New Multiproduct Pipeline (NMPP) Alliance for the monitoring of construction phase. 2009-2017. • Olifants River Water Resources Development Project, Steelpoort, Mpumalanga, RSA. EIMS was appointed to undertake the required environmental monitoring (noise, air quality, and water quality) for the construction of the Phase 1C of the bulk water pipeline. Project manager, 2012-2017. • GSW Dilokong Chrome Mine Due Diligence, Limpopo, RSA. Environmental lead to undertake an environmental due. 2017. • Tshipi é Ntle Manganese Mine Environmental Due Diligence, Kathu, Northern Cape, RSA. Project manager and senior consultant (in association with GSW) for an environmental review to inform a due diligence being undertaken. 2017. • Libra Due Diligence, Mpumalanga and Free State Province, RSA. Project manager and senior consultant to conduct a high level environmental review and due diligence study for the Anglo Libra project (incl various Anglo Coal assets) for Mindset Mining Consultants, 2016. • Sedgman Environmental Training, Pretoria, RSA. Compiled and presented a training workshop to Sedgman Engineers, focusing on the application and interpretation of the South African Environmental Laws, in relation to their operations and client profile. 2017. • EIA and EMP for the Transnet Richards Bay Coal Line: Overvaal Tunnel, Mpumalanga Province. Project manager, responsible for successful completion of the EIA. 2015-2016. • Tetra 4 Virginia Natural Gas Production, Water Monitoring, Free State, RSA. Project manager appointed to undertake surface and groundwater sampling to establish an environmental baseline and to monitor the actual impacts associated with the proposed natural gas production activities. 2015-2017. • Drafted the 2014-2019, 3rd Edition Environmental Management, Plan (compiled in terms of Section 11(2) of the National Environmental

SLW-8

Management Act 1998 (act 107 of 1998), for the National Department of Energy. Project manager and report writer. 2014-2015.

- Environmental Advisory to the Government Technical Advisory Centre, Public Private Partnership Unit. Environmental lead in a team of consultants providing consulting services to report to the GTAC on the lessons learn from past PPP's and to suggest means of improving the process for future PPP's. 2015.

- Eskom Lambda 400-765kV Sub-station and Associated Transmission Lines, Mpumalanga, RSA. Project manager and Environmental Assessment Practitioner for EIA. 2010-2012.

Mine Closure and Financial Provisioning:

- Determined Financial Provisions in accordance with the 'Guideline Document for the Evaluation of the Quantum of Closure-Related Financial Provision' provided by a Mine (DMR Guideline): Mooiplaats Colliery 2018; Exxaro Paardeplaats Coal Mine- Update 2018.

- Final Rehabilitation, Decommissioning and Closure Plan (FRDCP) prepared in accordance with the requirements of the NEMA Financial Provisioning Regulations (2015) (NEMA GNR 1147): Tetra 4 Virginia Natural Gas Project, 2017; Motuoane Gas Hennenman Exploration Right-2017; Motuoane Gas Ladysmith Exploration Right- 2017; Sungu Sungu Dannhauser Exploration Right- 2016; Kangala Colliery- Eloff Phase 3 Pit-2020; Anker Coal Elandsfontein Colliery-2021.

- Review of closure plans and financial provisions for closure as a component of Due Diligence and/or Competent Persons Reports: Environmental Review for 5 large Coal mining operations held by Exxaro- 2018; Environmental Review for Dilokong Chrome Mine- 2017; Environmental Review for Tshipi Mine- 2017; Environmental Review on numerous large coal mines held by Anglo Coal-2016.

Environmental Monitoring:

- Project manager and senior environmental scientist for the construction phase environmental monitoring on the Olifants River Water Resources Project Phase 2C (bulk water pipeline). The project included monitoring of water (point and diffuse), air quality (PM10 and fallout dust), and noise to ensure and guide compliance with the environmental specifications of the construction phase EMPR.

- Project manager and senior environmental scientist for the water resource monitoring of the Tetra4 Virginia Natural Gas Production Project. This includes specialist low-flow sampling od dissolved gases in the groundwater as well as general water quality parameters in both regional ground and surface water resources.

- Project Director for the routine water resource (surface and groundwater) monitoring being undertaken for the United Manganese of the Kalahari

JL28

	(UMK), manganese mine in Northern Cape. Responsible for technical and quality review and oversight.	
Period: January 2002-December 2010	Organisation: EIMS	Position: Senior Environmental Assessment Practitioner
Key Projects/Assignments	Project Manager and Environmental Assessment Practitioner for the following: • Environmental applications, including EMs, and mining permit applications, for various (7 Packages including N1, N3, N12, R23, and R24) Gauteng road upgrades as part of the Gauteng Freeway Improvement Project. EIMS was also appointed to undertake the role of independent ECO's for certain GFIP Packages • EIA for OCGT Peaking Power Station within the Conga IDZ. • EIA for spent nuclear fuel storage facility at Pelindaba. • EIA for nuclear waste smelter at Pelindaba. • EIA and water-use licensing for an underground ash disposal facility in Mpumalanga Province. • EIA for the proposed upgrade of the effluent collection and treatment facilities at the South African Nuclear Energy Corporation, Pelindaba. • EIA for proposed Garona to Aries 400KV Transmission line. • EIA for numerous Golf Estates. • EIA for Market Street Underpass as part of the Provincial government Precinct and City Square (Johannesburg) CBD. • EIA's for numerous residential developments. • Scoping report for the Eskom Janus substation in Limpopo Province. • EIA's for low-cost housing developments in the East Rand, Ekurhuleni Metropolitan Council as part of the Regional Professional Team. • Environmental exemption process for a World Summit on Sustainable Development project, Moroka Dam, Gauteng Province. • Numerous environmental exemption applications for housing developments. • Environmental Scoping studies for Sentech telecommunication masts in Eastern Cape Province. • Environmental Studies for telecommunication facilities for Vodacom. • Environmental Studies for 150+ telecommunication facilities for Cell C and Siemens in five provinces. • Environmental Studies for Eskom Telecommunications.	

	Environmental Site Assessment and Remediation: • Participation in several Environmental Site Assessments in Gaborone (Botswana) and Mpumalanga. Strategic Environmental Assessment: • Participation in the compilation of the Strategic Environmental Assessment for the Hartbeespoort Dam area. ISO 14001 Environmental Management Systems and Auditing • Participation in the compilation of the ISO 14001 system (legal register) for Coega Development Corporation, Eastern Cape Province. • Participation in the compilation of the ISO 14001 system (legal register) for Matimba Power Station in Limpopo Province. Mining Related Permits and Rights • Environmental Management Programme and EIA for the Cranemere Gas Exploration Project in the Eastern Cape Province. • EIA and EMPR for the proposed Loopspruit Coal Mine, Mpumalanga Province. • Project Manager for in excess of 40 mining permit applications for the Transnet New Multi-products Pipeline, Inland and Trunkline (between Johannesburg and Durban). Applications submitted in 4 different provinces. • Project Manager for 5 Mining Permit Applications for the South African National Roads Agencies Gauteng Freeway Improvement Project. Numerous NEMA Section 24(G) Rectification applications for a broad spectrum of developments

EIMS ENVIRONMENTAL IMPACT MANAGEMENT SERVICES

CURRICULUM VITAE

Name:	Gideon Petrus Kriel
Nationality:	South African
Date of Birth:	1 September 1983
Profession:	Environmental Scientist
Professional Qualification/ Training:	M.Env.Sci Water Sciences; North West University (Potchefstroom Campus), 2008
	Implementation of Environmental Management Systems (ISO 14001); Centre for Environmental Management, North-West University (Potchefstroom Campus), 2007.
	Bringing Data into GIS (ArcGIS); GIMS (now ESRI SA), 2008.
	Tools for Wetland Assessment; Rhodes University, 2013
Professional Membership/ Registrations:	Registered Professional Natural Scientist (SACNSP- #400202/09) – Environmental Sciences
	Registered Environmental Assessment Practitioner (EAPASA- #2019/1451)
	Water Institute of Southern Africa (WISA) Member (21162)
Current Employer:	Environmental Impact Management Services (Pty) Ltd.

KEY EXPERIENCE

GP holds an M.Env.Sci (Water Sciences) Cum Laude from the North-West University (Potchefstroom Campus) and has been employed as an Environmental Consultant since 2007. GP is a Registered Professional Natural Scientist (South African Council for Natural and Scientific Professions) and a Registered Environmental Assessment Practitioner (Environmental Assessment Practitioner). He has delivered presentations locally and internationally concerning the use of bio-indicators for the determination of water quality, and has experience in a wide variety of environmental management projects including: Environmental Impact Assessments, Basic Assessments, Geographic Information Systems (GIS), Environmental Compliance Monitoring, Environmental Awareness Training, Aquatic Ecological Assessments, Drinking and Waste Water Treatment Process Audits, Wetland Delineation and Assessments, ISO 14001 Aspect Registers, Water Use Licence Applications, Waste Management Licence Applications and Integrated Waste and Water Management Plans (IWWMP).

CAREER SUMMARY

Period: July 2007- Current	Organisation: EIMS	Position: Senior Environmental Assessment Practitioner
Key Projects/Assignments	Senior Consultant: Responsible for the following aspects: • Technical review and direction;	

1628

- Quality control and assurance;
- Client management; and
- Marketing and business development.

Project Experience:

- Environmental Impact Assessment for the proposed Zonk'Izizwe Mixed Use Development in Midrand, Gauteng.
- Basic Assessments for the road upgrades for the Johannesburg Roads Agency (JRA).
- Environmental Impact Assessment for the proposed Thabeng Eco Reserve and Golf Estate, near Ohrigstad, Limpopo.
- Basic Assessment for the proposed TATA Steel KZN Clean Energy Project, Richards Bay, KwaZulu-Natal.
- Basic Assessment for the proposed IPM Clean Energy Project, Moon Nest, North-West Province.
- Compilation of ISO 14001 Aspect/Impact registers for Clover (Pty) Ltd.
- Basic Assessment for the proposed N17 Phase 2 project: Addition of Auxiliary Lanes Between the Roodebult Road Interchange and the Proposed Trichardts Road Interchange.
- Basic Assessment for the Proposed Early Warning System for the South African Nuclear Energy Corporation of South Africa (NECSA).
- Environmental Impact Assessment for the Proposed Water and Effluent Collection and Treatment Infrastructure Upgrade for the Nuclear Energy Corporation of South Africa (NECSA).
- Basic Assessment for the proposed Residential Development on Portions 16 & 17 of the Farm Wilgespruit 190 IQ, Wilgeheuwel, Roodepoort.
- Independent Environmental Control Officer for the Eye of Africa Golf Estate, Gauteng.
- Independent Environmental Control Officer for the Department of International Relations Head Office Construction, Pretoria.
- Water Use License Application for the Upgrade of the Low Level Bridge on Hyperion Drive, North Riding, Johannesburg.
- Diatom Water Quality Assessments for the Upgrade of the Low Level Bridge on Hyperion Drive, North Riding, Johannesburg.
- Basic Assessment for the Proposed Rand Water 1400mm diameter L17 Bulk Water Pipeline, Brakpan, Gauteng.
- Wetland Delineation for Anglo Platinum Potgietersrus Platinum Limited near Mokopane, Limpopo.

5608

- Independent Environmental Control Officer for the Knock-down and Rebuild of the Shell Range River Service Station, Gilview, Johannesburg.
- Independent Designated Environmental Officer for the Refurbishment of the South African National Roads Agency Limited (SANRAL) Dalpark Operations Centre, Brakpan.
- Waste Licence Application for the Proposed Water and Effluent Collection and Treatment Infrastructure Upgrade for the Nuclear Energy Corporation of South Africa (NECSA).
- Prospecting Rights Applications on behalf of the African Exploration Mining and Finance Corporation (Pty) Ltd for a variety of projects in Limpopo, Free State and North-West Provinces.
- Environmental Impact Assessment and Waste Management Licence Application for the Lusikisiki Sewer and Sewer Treatment Plant, Lusikisiki, Eastern Cape.
- Diatom Monitoring for the Lusikisiki Sewer and Sewer Treatment Plant, Lusikisiki, Eastern Cape.
- Appointed as a Blue Water Services Inspector for the 2012 Blue Water Services Audits by the Department of Water Affairs.
- Basic Assessment for the formalisation of Masibambane, Masibulele, Ilinge, Dacawa Gwentsha, Velvano, Mathemba Vuso in Mdantsane for the Buffalo City Metropolitan Municipality.
- Environmental Impact Assessment for the Proposed Sunny South Housing Development for the Buffalo City Metropolitan Municipality.
- Basic Assessment and Water Use Licence for the Mqonjwana Access Road for the Mbizana Local Municipality.
- Independent Environmental Control Officer for the East London Industrial Development Zone (ELIDZ): Infrastructure Services for the Zone 1B West Residential Development.
- Heritage Impact Assessment and Public Participation for the Proposed Reconstruction of Fleet Street, East London for the Buffalo City Metropolitan Municipality.
- Environmental Monitoring (Water Quality) for Phase 2 OD of the Olifants River Water Resources Development Project for Basil Read.
- Basic Assessment and Water Use Licence Application for the Proposed Sidwadeni River Access Road near Mthatha, Eastern Cape on behalf of the South African National Roads Agency (SOC) Limited.
- Basic Assessment and Water Use Licence Application for the Proposed Mngazi River Access Road near Port St Johns, Eastern Cape on behalf of the South African National Roads Agency (SOC) Limited.

- Independent Environmental Control Officer for the East London Industrial Development Zone (ELIDZ): Proposed MMOEM Facilities.
- Amalinda Fairlands Feasibility Study for the Buffalo City Metropolitan Municipality (CS Consulting).
- Independent Environmental Control Officer for the Lusikisiki Sewer and Sewer Treatment Plant, Lusikisiki, Eastern Cape.
- Independent Environmental Control Officer for the Noblesfontein Wind Energy Facility near Victoria West, Northern Cape Province.
- Independent Environmental Control Officer for the Reconstruction of Fleet Street, East London, Buffalo City Metropolitan Municipality, Eastern Cape Province.
- Transnet Freight Rail NEMA Section 24G Rectification Application – Coega Station to Tankatara Level Crossing, Coega, Eastern Cape.
- Independent Environmental Control Officer for the Sunny South Housing Development for the Buffalo City Metropolitan Municipality.
- Vincent-Berea Local Spatial Development Framework, CS Consulting (Buffalo City Metropolitan Municipality), East London, Eastern Cape.
- Participatory Based Planning Support to Informal Settlements Upgrading Projects in Buffalo City Metropolitan Municipality, CS Consulting, Eastern Cape.
- Motopo Free State Wetland Delineations, Virginia, Free State.
- Puma Energy Fuel Depot Wetland Delineation, Nelspuit, Mpumalanga.
- Mdantsane Roads Cluster 2 Environmental Control Officer, Buffalo City Metropolitan Municipality.
- Gluricich Chemical Removal at Vodacom Site, East London.
- Internal Environmental Management System Audits (ISO 14001) for the East London Distribution Centre and Ladismith Plant for Parmalat South Africa.
- Environmental Control Officer for the Eskom Albany-Mimosa 66KV Distribution Line near Alicedale, Eastern Cape.
- Environmental Impact Assessment for the Proposed Algoa Basin Oil & Gas Production Project for Aberdeen Offshore Engineering.
- Basic Assessment for the Proposed Ablution Facilities Along the Coast for Nyandeni Local Municipality.
- Environmental Control Officer for the Eskom Wittekleibosch-Dieprivier 132kV Power Line and Switching Station, Tsitsikamma, Eastern Cape.
- Specialist Walkdown and Site Specific EMPR for the Eskom Ankerlig-Omega Power line, Western Cape.

	• Wetland Assessment for the Lichtenburg Hospital Basic Assessment Process for PH Bagale (on behalf of the Department of Health). • Update of the Integrated Waste and Water Management Plan Eskom Lethabo Power Station, Free State. • Basic Assessment for the Upgrade of the Loop 16 (Garlep) Road for ACWA Power, Grobblershoop, Northern Cape. • Prospecting Rights Application and Basic Assessment for Black Mountain Mining, Aggeneys, Northern Cape. • Basic Asessment for the Eskom Riverbank IPP Projects, Eastern Cape. • Environmental Control Officer for the SANRAL N2 Section 15 from Buffalo River (km 2,94) to Braidbach Intersection (km 9,8) and the R63 from Alexandra Road (km 0) to Bhisho, Eastern Cape. • Environmental Control Officer for the Greenfields section of the SANRAL N2 Wild Coast Toll Highway (Southern Section), Eastern Cape. • Basic Assessment for the Upgrading to a Surface Standard Portion of Road DR06606 +1-12KM, Eastern Cape Department of Roads and Public Works, Eastern Cape. • Transnet TM2 Aquatic Monitoring Programme. • Prospecting Right Applications and Basic Assessment Processes for Black Mountain Mining near Aggeneys, Northern Cape. • Eskom Amathole Stormwater Environmental Control Officer, Eastern Cape. • Update of the ACWA Bokpoort Consentrated Solar Plant Integrated Waste and Water Management Plan, Northern Cape. • Update of the Rehabilitation Strategy and Implementation Plan, Mpumalanga. • Basic Assessment and Water Use Licence Application for the Proposed Megamor Park Extension, Meisieshalt, East London for Umbra Trading 11. • Creation of the Ekurhuleni Metropolitan Municipality Parks GIS Layer. • Enviro-legal review for Bax Kaplan Russel for a Waste Processing Facility in Wilsonia, East London. • Enviro-Legal Review: Demonstration of On-Site Faecal Sludge Treatment in East London, Impilo Yabantu Services (Pty) Ltd. • Umgeni Raw Water Management Audit for SizweNtsalubaGobodo, Pietermaritzburg. • Umgeni Waste Water Management Audit for SizweNtsalubaGobodo, Pietermaritzburg.

1603

- Competent Persons Report (Environmental) for the Ntshovelo Mining Resources (Pty) Ltd Welgemeend Colliery.
- Umgeni Potable Water Management Audit for SizweNtsalubaGobodo, Pietermaritzburg.
- Cambridge Pedestrian Bridge Enviro-legal Interpretation for CBM Consulting Engineers.
- Komati Power Station Legal Audit for Eskom.
- Beaconhurst Drive Enviro-legal Interpretation for CBM Consulting Engineers.
- Port of Ngqura Tank Farm Infrastructure Specialists Services for Transnet Group Capital.
- Prospecting Rights Application and Basic Assessment for Black Mountain Mining, Northern Cape.
- Independent Environmental Control Officer for the East London Industrial Development Zone (ELIDZ): GW1 Facilities in Zone 1A.
- Basic Assessment and Water Use Licence Application for the Proposed Summerpride Erf 107 Residential Development, East London.
- Harmony Target 1 & 2 Performance Assessment Audits, Welkom
- Harmony President Steyn North (Steyn 3, 7 & 9) Performance Assessment Audits, Welkom.
- City of Ekurhuleni Tsakane Sewer Pump Station Basic Assessment, Ekurhuleni.
- Eskom Duvha Power Station Legal Compliance Audit.
- Buffalo City Metropolitan Municipality Eastern Beach Sewer Upgrade Environmental Officer, East London.
- Transnet Group Capital Coega Kop Quarry Water Use Licence Application.
- SCAW Dimbaza Foundry Groundwater Monitoring, Dimbaza.
- Mulilo Struisbult PV2 Grid Connection Basic Assessment, Copperton.
- Mulilo Struisbult PV2 EMPr Amendment, Copperton.
- Tosaco Offshore Exploration Environmental Impact Assessment.
- Azinam Offshore Block 2B Stakeholder Engagement.
- TGS Orange Basin Offshore Reconnaissance Basic Assessment.
- GIS work for a large amount of projects from 2007 - Present including the following: the identification and mapping of sensitivities and interested and affected parties, the delineation of site boundaries, the identification of alternative development sites, geo-referencing of old maps and technical drawings, production of informative maps for Basic Assessments,

GROUNDS OF APPEAL	RESPONDING STATEMENT	COMMENT BY THE DEPARTMENT / DNR
1. Issues with the consultation process: the co-op believes the consultation process was not done correctly, we do not believe that the information that was presented is accurate. We know that the government is for oil and gas, but as a community and a small-scale fisher organization we are against it. We have seen this happen in other countries, and it has messed the whole sea life up. That's why we see foreign boats in our waters. We say no but the government says yes. In a few years time we'll be like all the other countries with nothing in our waters and nothing for the generation behind us. We strongly say no to seismic surveys and oil and gas development.		
2. It is not an open and transparent participatory process according to NEMA. We go and listen to the consultations but do not consent to a seismic survey. TGS states that a mitigation measure is to "consult with communities on potential ways in which to		

1637

make a positive contribution to the communities." Why isn't this part of the consultation process? The private sector and the government should be coming to affected communities such as Port Nolloth with this question, instead of coming with only one option – either seismic surveys or exploration drilling. Why has nobody asked what the Port Nolloth community wants for development? Why would we agree to something that has absolutely no benefit for us? Meaningful consultation should allow us to decide what we want, not being told something that has the potential to destroy our livelihood and that is so significant to our culture.		
3. TGS states there is a "perceived impact" of the oil/gas industry on the fishing industry, not the actual impact on catch rates. We do not believe this to be true, as there have been studies and evidence of the harms of seismic surveys and issues with oil and gas developments, e.g., blowouts, that impact fish for years to come. For example, after the Deepwater Horizon blowout in 2010 in the Gulf of Mexico, fish and dolphins are still testing positive for the chemicals found in the oil that spilled. There		

1638

are scientific reports that were not included in the EIA that show different impacts on species from the noise of air guns used in seismic surveys. The difference in scientific information that is presented in the consultations and EIAs is concerning. Further, we are concerned about who is going to monitor the impacts of the seismic survey, and how will fishers and other coastal livelihoods be compensated if there is harm to marine life as a result of the survey.		
4. Does not meet South Africa's climate change goals, e.g., Paris Agreement and Kyoto Protocol, and effort to achieve net zero. The push for oil and gas does not align with South Africa's climate change goals, where the country is a signatory to meeting these challenges and reducing its carbon footprint. We believe that this seismic survey violates these agreements and our Constitutional right to Section 24 on the Environment. It violates our right to health and well-being as it affects our livelihood and food security. This survey has a direct impact on pollution and ecological degradation, does not promote conservation, and is not promoting justifiable economic and social development. There are no economic benefits of oil and		

1639

gas to the Port Holloth community.		
5. The government is allowing permits for activities that harm the ocean yet are diminishing quotas. We as small-scale fishers do not harm the ocean, yet are severely impacted by seismic survey activities. As TGS states, our livelihoods are "already compromised due to the fishing quota system, over-fishing, lack of employment opportunities, pollution, effects of climate change and the revent Covid pandemic." The government is not alleviating any of these challenges by allowing a seismic survey and oil and gas development. Even though this seismic survey is not in the exact boundary of our fishing grounds, we are still concerned that it will affect the migration patterns of the fish. Climate change and overfishing is already impacting those patterns and the amount of fish in the ocean, so please we do not want another activity that will harm the fish we depend on for our livelihood.

ANNEX B

APPEAL PURSUANT TO SECTION 43(1A) OF THE NATIONAL ENVIRONMENTAL MANAGEMENT ACT, 1998 AND SECTION 4(1) OF THE NATIONAL APPEAL REGULATIONS OF 2014 AGAINST ENVIRONMENTAL AUTHORISATION GRANTED TO TGS GEOPHYSICAL COMPANY (UK) FOR THE PROPOSED ORANGE BASIN RECONNAISSANCE PERMIT PROJECT

INTRODUCTION

1. This is an appeal to the Honourable Minister of Forestry, Fisheries and the Environment ("**Appeal**" to the "**Minister**"), directed to the Director: Appeals and Legal Review of the Department of Forestry, Fisheries and the Environment ("**DFFE**"), to set aside the decision of the Director-General of the Department of Mineral Resources and Energy (as "**DG**" or "**DMRE**") dated 17 April 2023 granting environmental authorisation to TGS Geophysical Company (UK) (as "**Third Respondent**") allowing for a 3D seismic survey off the West Coast of South Africa.

2. The Minister should set aside the decision to grant authorization because the Environmental Basic Assessment Report (BAR) did not comply with NEMA in several ways. The decision to grant authorization violates various provisions of NEMA, including the requirements for granting environmental authorizations and the National Environmental Management Principles. The BAR and the decision-maker failed to establish the need and desirability of the Project, failed to adequately consider marine impacts, and neglected to assess the cumulative impacts of the Project. The Second and Third Respondent also failed to engage in meaningful consultation, violating principles of fair administrative decision-making and the right of affected communities to be consulted. This failure to consult is inconsistent with NEMA's requirement to promote participation and take into account the interests of all parties. Moreover, the decision-maker disregarded NEMA Principles, including the precautionary principle and the principle of sustainable development, as well as the constitutional right to a non-harmful environment. The decision therefore to issue the authorization and the reasons provided are deemed irrational and unreasonable.

3. The Appellant submit this appeal on the following grounds:

3.1. Ground 1: A flawed and misguided need and desirability assessment

3.1.1. Climate Change Impacts.

3.1.2. The climate crisis.

3.1.3. South Africa's international climate change commitments.

3.1.4. Need for seismic data.

3.2. Ground 2: Failure to adequately consider marine impacts

3.2.1. Underwater sound from acoustic seismic surveys.

3.2.2. Harms to marine life.

3.2.3. Acoustic Modelling

3.2.4. Heightened Legislative Requirements are Not Considered for Critical Biodiversity Areas (CBAs), Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs).

3.2.5. CBAs

3.2.6. EBSAs and MPAs.

3.2.7. Cape Fur Seals

3.2.8. Whale and Dolphins.

3.2.9. Fish.

3.2.10. Zooplankton.

3.2.11. The proposed mitigation measures are inadequate to prevent unacceptable harm to marine life.

3.2.12. Simultaneous Surveys.

3.2.13. Lack of baseline noise assessment.

3.2.14. Chronic Noise Impacts.

3.3. Ground 3: Failure to adequately assess cumulative impacts

3.4. Ground 4: Failure to conduct meaningful consultation with communities and local people (and in particular small-scale fishers), within the public participation process, including the Social Impact Assessment process.

3.5. Ground 5: The FBAR does not contain a proper and objective assessment of the negative impacts of the project on people's human rights

3.6. Ground 6: Failure to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008

3.7. Ground 7: Failure to provide adequate reasons for the decision.

3.8. Ground 8; Decision to grant authorisation contravenes NEMA Principles, the Constitution and PAJA

4. The Authorisation, with reference number 12/1/040, was granted in terms of regulation 24 of the National Environmental Management Act, 1998 ("**NEMA**") Environmental Impact Assessment Regulations, 2014 ("**EIA Regulations**").

5. The Appeal is lodged in terms of section 43(1A) of NEMA, which provides that: "*Any person may appeal to the Minister against a decision made in terms of this Act or any specific environmental management Act by the Minister responsible for mineral resources or any person acting under his or her delegated authority*", read with the NEMA National Appeal Regulations, 2014[1] ("**the Appeal Regulations**"), which provide for the submission of an appeal within 20 days from the date that the notification of the decision for an application for environmental authorisation was sent to the registered interested and affected parties (**I&APs**) by the Applicant (26 April 2023).[2]

6. In accordance with the requirements of Regulation 4(2)(a) of the Appeal Regulations:

   6.1. this Appeal is submitted in writing in the form obtained from the Appeal Administrator, and accompanied by this more detailed appeal document, being a statement setting out the grounds of appeal ("**the Grounds of Appeal**"). The Appellants are entitled to also submit these more detailed Grounds of Appeal as the Appeal submission. This submission must be taken into account by the Minister in making a decision on the Appeal;

   6.2. to the extent possible, the Appeal is accompanied by relevant supporting documentation which is referred to in this Appeal submission - attached as Annexure B; and

[1] GN R 993 GG 38303 of 8 December 2014.
[2] Regulation 4(1)(a) NEMA National Appeal Regulations, 2014.

6.3. we confirm, in compliance with Regulation 4(1) of the Appeal Regulations, that this Appeal is submitted within 20 days[3] from the date of notification to I&APs to the Appeal Administrator. A copy of the Appeal will be provided to the Applicant and to those registered I&APs, and organs of state with an interest in the matter, insofar as possible and within time and cost constraints. The statement regarding compliance with Regulation 4(1) is contained in the cover letter to which these Grounds of Appeal are attached. In any event, we confirm compliance with Regulation 4(1).

7. The Appellants further submit that there are grounds for judicial review under the Promotion of Administrative Justice Act, 2000 ("**PAJA**") because the Authorisation comprises administrative action that *inter alia*:

7.1. is unconstitutional or unlawful;[4]

7.2. was taken because of the failure to consider relevant considerations;[5]

7.3. is not rationally connected to the information before the decision-maker in making the Decision or to the reasons provided by the decision-maker for the Decision;[6] and

7.4. is so unreasonable that no reasonable person could have granted it.[7]

PARTIES

8. The First Appellant is **Natural Justice.**

8.1. Natural Justice: Lawyers for Communities and the Environment is a non-profit organization specializing in environmental and human rights law in Africa – with a focus on the pursuit of social and environmental justice for local and

[3] The Appellants submit that the process provided for in the Appeal Regulations, in particular the requirement to submit an appeal in 20 days of the notification, severely prejudices the Appellants and infringes on their rights to a fair process. The Appellants continue to assert that the unreasonably short timeframes and onerous notification requirements of regulation 4(1), among others, render the Appeal Regulations a violation of the rights to just administrative action, and are thus unconstitutional.

[4] PAJA section 6(2)(d),(f)(ii) and (i).
[5] PAJA section 6(e)(iii).
[6] PAJA section 6(f)(ii)(cc) and (dd).
[7] PAJA section 6(h).

5428

indigenous communities. Natural Justice offers direct support to local and indigenous communities impacted by the ever-increasing demand for land and natural resources..

9. The Second Appellant is the Green Connection.

9.1. Green Connection is a registered non-governmental organisation, that believes that economic growth and development, improvement of socio-economic status and conservation of natural resources can only take place within a commonly understood framework of sustainable development. The Green Connection aims to provide practical support to both the government and non-governmental/civil society sectors, which are an integral part of sustainable development.

10. The Appellants have legal standing to bring the Appeal not only in terms of section 43 of NEMA, but also to enforce environmental laws in terms of NEMA section 32, in that they *inter alia* act: *"(c) in the interest of or on behalf of a group or class of persons whose interests are affected; (d) in the public interest; and (e) in the interest of protecting the environment."*[8] The Appellants act in the interest of, or on behalf of, persons who, for practical reasons, are unable to institute such proceedings, including members of coastal communities who do not have the capacity or resources to do so, in the interests of coastal communities who are affected by the proposed seismic activities, in the public interest, and in the interest of protecting the environment, to further the objectives of section 24 of the Constitution of the Republic of South Africa, 1996 ("the Constitution") and NEMA.

11. The Appellants are also Registered Interested and Affected parties (I&AP) in respect of the application process for this authorisation.

BACKGROUND AND DESCRIPTION OF THE PROJECT

12. The proposed project area is located between approximately 120 km offshore of St Helena Bay, extending north along the western coastline to approximately 230 km

[8] NEMA section 33(1)(c)-(d).

offshore of Hondeklip Bay over a number of petroleum licence blocks. The application area for the proposed 3D seismic survey is approximately 57 400 km² in extent. TGS proposes that a single survey vessel equipped with seismic sources and streamers be used. The proposed 3D survey would be supported by two escort vessels. It is estimated that the 3D survey will take 70 days (including downtime).[9] The area proposed for the seismic survey is a large under-explored area with potential for both oil and gas.

13. On the 25th of November 2022, the Applicants submitted comments on the draft Basic Assessment Report prepared as part of the Environmental Impact Assessment (EIA) process. As mentioned above, the DG granted the Project an Environmental Authorisation on 17 April 2023, and the Appellants received notification of the decision on 26 April 2022.

14. The Reasons for the Decision are set out in Annexure 1 to the Authorisation.

GROUNDS OF APPEAL

15. The decision to grant the Authorisation should be set aside by the Minister because the final Environmental Basic Assessment Report ("BAR") failed to comply with NEMA in various respects; and the Director General"s decision to grant the Authorisation contravenes various provisions of NEMA, including the requirements for granting environmental authorisations, the requirements of the National Environmental Management Act and the National Environmental Management Principles (section 2 of NEMA) ("NEMA Principles"), in that:

    15.1. the need and desirability of the Project has not been established, as required by regulation 18 of the EIA Regulations read with regulation 23(3) and Appendix 3 to the EIA Regulations.

    15.2. the BAR and the DG failed to adequately consider the marine impacts and therefore have failed to meet the requirements of, inter alia, section 24O(1) NEMA to account for all relevant factors,[10] in particular those

[9] BAR Executive Summary, pxvi.
[10] NEMA, section 24O1(b).

regarding the pollution, environmental impacts or environmental degradation "*likely to be caused if the application is approved*",[11] as well as any guidelines, departmental policies, and environmental management instruments and any other information in the possession of the competent authority relevant to the Application.[12] This is also in contravention of the NEMA requirement to ensure that the activity's potential environmental impacts are properly assessed;[13]

15.3. The FBAR and DG have failed to adequately assess and consider the cumulative impacts of the Project, as required by the NEMA EIA Regulations, Appendix 3 section 3(j)(i).

15.4. TGS, and its appointed Environmental Assessment Practitioner ("EAP", has failed to engage in meaningful consultation in violation of the principles of fair administrative decision-making and the right of interested and affected communities to be meaningfully consulted prior to a decision on authorisation being made, and in violation of section 2(4)(f) of NEMA, which stipulates that the participation of all interested and affected parties in environmental governance must be promoted, and all people must have the opportunity to develop the understanding, skills and capacity necessary for achieving equitable and effective participation, and participation by vulnerable and disadvantaged persons must be ensured. It is also inconsistent with section 2(4)(g) of NEMA, which requires that decisions must take into account the interests, needs and values of all interested and affected parties, and this includes recognising all forms of knowledge, including traditional and ordinary knowledge.

15.5. the DG failed to consider and/or give effect to: the NEMA Principles, including the precautionary principle and the principle that requires development to be environmentally, socially and economically sustainable; and the Constitutional rights to an environment that is not

[11] NEMA, section 24O1(b)(i).
[12] NEMA, section 24O2(b)(viii).
[13] NEMA, section 24(4)(a)(iv).

harmful to health or wellbeing – as enshrined in section 24 of the Constitution of the Republic of South Africa, 1996 ("the Constitution"). The decision to issue the Authorisation and the reasons provided therefore are, furthermore irrational and unreasonable, and thus in contravention of PAJA.

15.6. The DG failed to consider relevant coastal management considerations or to comply with the National Environmental Management: Integrated Coastal Management Act 24 of 2008.

15.7. Ground 7: The DG failed to provide adequate reasons for the decision.

15.8. Ground 8. Decision to grant authorisation contravenes NEMA Principles, the Constitution and PAJA

Ground 1: A flawed and misguided need and desirability assessment

16. The NEMA EIA Regulations stipulate that a basic assessment report must include a motivation for the need and desirability for the proposed development, including the need and desirability of the activity in the context of the preferred location.[14]

17. Section 5 of the BAR includes a motivation of need and desirability for the proposed 3D seismic survey. Unsurprisingly, the BAR focusses on justifying the 'need and desirability' of the proposed project and fails to reflect views critical to 3D seismic surveys and offshore oil and gas exploration (and ultimately production). As a consequence, the 'need and desirability' assessment provided in the BAR follows

---

[14] NEMA EIA Regulations, Appendix 1, section 2(c). With regard to need and desirability, a distinction is drawn between the 'general purpose and requirements' of the proposed activity and 'need and desirability'. The 2017 Guideline on Need and Desirability states as follows (at p10):

> In order to properly interpret the EIA Regulations' requirement to consider "need and desirability", it is necessary to turn to the principles contained in NEMA, which serve as a guide for the interpretation, administration and implementation of NEMA and the EIA Regulations. With regard to the issue of "need", it is important to note that this "need" is not the same as the "general purpose and requirements" of the activity. While the "general purpose and requirements" of the activity might to some extent relate to the specific requirements, intentions and reasons that the applicant has for proposing the specific activity, the "need" relates to the interests and needs of the broader public.
>
> ...
>
> The consideration of "need and desirability" in EIA decision-making therefore requires the consideration of the strategic context of the development proposal along with the broader societal needs and the public interest. The government decision-makers, together with the environmental assessment practitioners and planners, are therefore accountable to the public and must serve their social, economic and ecological needs equitably. Ultimately development must not exceed ecological limits in order to secure ecological integrity, while the proposed actions of individuals must be measured against the short-term and long-term public interest in order to promote justifiable social and economic development – i.e. ensuring the simultaneous achievement of the triple bottom-line. Considering the merits of a specific application in terms of the need and desirability considerations, it must be decided which alternatives represent the "most practicable environmental option", which in terms of the definition in NEMA and the purpose of the EIA Regulations are that option that provides the most benefit and causes the least damage to the environment as a whole, at a cost acceptable to society, in the long-term as well as in the short-term. (emphasis added)

The Guideline requires need and desirability assessments to address the impact of planned activities on global and international responsibilities relating to the environment, including climate change (at p11).

the pattern of previous seismic survey EIAs by (among other things) limiting the assessment of potential impacts to the proposed 3D seismic survey, with no assessment of the need and desirability of exploring for (and ultimately producing and using) new oil and gas reserves (including in the context of the climate change crisis and the right to food). The assessment also includes a section motivating the 'need' for seismic data.

18. It is noted that the BAR Needs and Desirability analysis indicates that the proposed project '*aims to identify oil and gas resources to be used in… energy production and/or processing or manufacturing of materials*'.[15] The BAR also claims in passing that "seismic surveying is not only used for petroleum and natural gas exploration and development, it can in certain instances also be used for development of offshore wind, geothermal energy, and low-carbon solutions such as carbon capture and storage and also more generally for providing more insight and understanding into the regional geology of the area for scientific purposes." This statement about other uses is misguided and irrelevant. These other purposes of the projects surveying results are speculative at best, and have far less impacts on the ocean than oil and gas surveying.[16] It is also abundantly clear from the BAR that the main purpose of this project is to survey for oil and gas deposits.

19. The BAR concludes that '*[a]s a result of the fact that this project entails only survey activities, it is anticipated that this project will not lead to a significant impact on the receiving environment*'.[17] In line with this, the BAR does not consider or assess the potential climate and other negative impacts of subsequent oil and gas exploration,

---

[15] BAR, Item 1.7.1, p24.

[16] For example, the offshore wind industry does not use airguns, and instead relies on High Resolution Geophysical (HRG) surveys to map the ocean bottom and its shallow geological features. That technology, such as echosounders, sidescan sonar, and sparkers, uses considerably less power as compared to seismic airguns and also tends to operate at higher frequencies. Not only do higher frequency sounds dissipate more quickly in the ocean but they also tend to fall outside of the general hearing range of baleen whales, such as humpbacks and right whales. The use of seismic surveying to develop offshore wind is the equivalent of using a hammer when a feather could do the job. The area that is being surveyed is also 120 – 230 km offshore and includes deep to ultradeep depths between 1,500 – 4,000m. It would not be feasible to install a fixed nor floating turbines at those depths, as they are more suitable for depths of less than 50m and 50 to 1,000m, respectively. Lastly, a World Bank analysis does not find the area TGS is surveying to be ideal for offshore wind generation. ESMAP. 2019. Going Global: Expanding Offshore Wind to Emerging Markets at p. 20-21. Washington, DC: World Bank ("fixed foundation is considered technically viable in areas with water depth less than 50 m and average wind speeds over 7 m/s. Floating wind is considered technically viable with water depths from 50 m up to 1,000 m.").

[17] Ibid, Item 1.8.3, p24.

production and use. In other words, it fails to consider the lifecycle impacts associated with exploring for and exploiting oil and gas resources. Yet, at the same time, it does consider the positive impacts should oil and gas be eventually produced, such as the claim that it will provide energy security to South Africa. This self-serving analysis is not only deceiving, it is unlawful.

Climate change impacts

20. The BAR states that from a climate change perspective, it is '*not currently possible to accurately assess the risks associated with oil and gas activities, given that the specific details of these potential future activities are not known and therefore climate change impacts would need to be assessed in detail during any subsequent Scoping and EIA processes for any potential subsequent oil and gas production projects*'.[18] As a result, the BAR does not conduct any climate change impact assessment, even in broad terms.

21. It is relevant to note that the issue of whether the decision-maker properly considered climate change impacts was referred to in the judgment of the full bench of the Makhanda High Court in the Shell Wild Coast seismic survey case.[19] The court stated in its judgement that the intervening parties' contention that the decision-maker gave no proper consideration to climate change impacts of the decision to grant the exploration right is an important factor to be considered in the process of granting an exploration right. The court referred to expert testimony relied upon to support this contention, which showed that '*most of the discovered reserves of oil and gas cannot be burnt if we are to stay on the pathway to keep global average temperature increases below 1.5 degrees Celsius. Authorising new oil and gas exploration, with its goal of finding exploitable oil and/or gas reserves and consequently leading to production, is not consistent with South Africa complying with its international climate change commitments*'.[20]

---

[18] BAR, p33.

[19] *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, at paras 120 to 125.

[20] Ibid, at para 121.

22. The court noted that according to the respondents in that case, climate change considerations are irrelevant when considering an application for an exploration right, and these considerations are premature because they fall to be considered at a much later stage.

23. The court pointed out that on the authority of the *Save the Vaal* case,[21] the '*processes are discrete stages in a single process that culminates in the production and combustion of oil and gas, and the emission of greenhouse gases that will exacerbate the climate crisis and impact communities' livelihoods and access to food*'.[22] The court went on to state that the respondent's thesis does not find support in *Earthlife Africa Johannesburg v Minister of Environmental Affairs and Others* either, and referred approvingly to the following passage in Murphy J's judgement:

> The absence of express provision in the statute requiring a climate change impact assessment does not entail that there is no legal duty to consider climate change as a relevant consideration and does not answer the interpretative question of whether such a duty exists in administrative law. Allowing for the respondents' argument that no empowering vision in NEMA or the regulations explicitly prescribes a mandatory procedure or condition to conduct a formal climate change assessment, the climate change impacts are undoubtedly a relevant consideration as contemplated by section 24O of NEMA for the reasons already discussed. A formal expert report on climate change impacts will be the best evidentiary means of establishing that this relevant factor in its multifaceted dimensions was indeed considered, while the absence of one will be symptomatic of the fact that it was not.[23]

24. The court in the Shell Wild Coast seismic survey case went on to state the following:

> It seems clear from the aforegoing, even taking into account the contentions raised by the respondents, that, had the decision-maker had the benefit of considering a comprehensive assessment of the need and desirability of exploring for new oil and gas reserves for climate change and the right to food perspective, the decision-maker may well have concluded that the exploration is neither needed nor desirable.[24] (emphasis added)

[22] Ibid, para 123.
[23] Ibid, para 124.
[24] Ibid, para 125.

25. The Green Connection and Natural Justice submit that the BAR is deficient, and the Needs and Desirability analysis incomplete, without at the very least a broad assessment of the climate change impacts should commercially exploitable oil and gas resources be identified through the proposed seismic survey (and should these resources be produced and utilised). It would be pointless to authorise this (and other) 3D seismic surveys should such an assessment conclude that the development of new oil and gas fields is incompatible with South Africa's climate change commitments.

The 'climate crisis'

26. The need and desirability (from a climate change perspective) of conducting a 3D seismic survey (which – as mentioned above – the BAR aims to identify oil and gas resources to be used in energy production and/or processing or manufacturing of materials) is particularly important given that climate change has been acknowledged as a 'crisis' with human-induced climate change impacts being experienced in every region. It is also recognised that the climate change 'crisis' requires immediate, rapid and large-scale reductions in greenhouse gas (GHG) emissions to limit global warming to 1.5°C (including accelerated action in this decade to reduce global carbon dioxide emissions by 45 per cent by 2030 relative to the 2010 level and to net-zero around mid-century). In support of these submissions, some of the recent developments relating to the climate crisis are discussed briefly below.

27. In August 2021, the Intergovernmental Panel on Climate Change (IPCC) (an international body for assessing the science related to climate change) released its 6th Assessment Report (AR6).[25] In its summary for policymakers, the IPCC indicates (among other things) that:

    27.1. It is unequivocal that human influence has warmed the atmosphere, ocean and land, and that widespread and rapid changes in the atmosphere, ocean, cryosphere and biosphere have occurred;[26]

[25] Climate Change 2021: The Physical Science Basis, available online at: https://www.ipcc.ch/report/sixth-assessment-report-working-group-i/
[26] Para A.1

27.2. The scale of recent changes across the climate system as a whole – and the present state of many aspects of the climate system – are unprecedented over many centuries to many thousands of years;[27]

27.3. Human-induced climate change is already affecting many weather and climate extremes in every region across the globe. Evidence of observed changes in extremes such as heatwaves, heavy precipitation, droughts, and tropical cyclones, and, in particular, their attribution to human influence, has strengthened since AR5;[28]

27.4. Global surface temperature will continue to increase until at least mid-century under all emissions scenarios considered, and that global warming of 1.5°C and 2°C will be exceeded during the 21st century unless deep reductions in CO_2 and other GHG emissions occur in the coming decades;[29]

27.5. Many changes in the climate system become larger in direct relation to increasing global warming. They include increases in the frequency and intensity of hot extremes, marine heatwaves, heavy precipitation, and, in some regions, agricultural and ecological droughts; an increase in the proportion of intense tropical cyclones; and reductions in Arctic sea ice, snow cover and permafrost;[30]

27.6. Continued global warming is projected to further intensify the global water cycle, including its variability, global monsoon precipitation and the severity of wet and dry events;[31]

27.7. Many changes due to past and future GHG emissions are irreversible for centuries to millennia, especially changes in the ocean, ice sheets and global sea level;[32]

27.8. From a physical science perspective, limiting human-induced global warming to a specific level requires limiting cumulative CO_2 emissions, reaching at least net zero CO_2 emissions, along with strong reductions

[27] Para A.2
[28] Para A.3
[29] Para B.1
[30] Para B.2
[31] Para B.3
[32] Para B.5

in other GHG emissions. Strong, rapid and sustained reductions in CH_4 emissions would also limit the warming effect resulting from declining aerosol pollution and would improve air quality.[33]

28. On 9 August 2021, the IPCC issued a press release relating to its AR6 report. It states that the report provides new estimates of the chances of crossing the global warming level of 1.5°C in the next decades, and finds that unless there are immediate, rapid and large-scale reductions in GHG emissions, limiting warming to close to 1.5°C or even 2°C will be beyond reach.[34]

29. Also on 9 August 2021, UN Secretary-General António Guterres described the AR6 report as nothing less than "*a code red for humanity. The alarm bells are deafening, and the evidence is irrefutable*". (emphasis added)

30. Guterres is reported as noting that the internationally agreed threshold of 1.5 degrees above pre-industrial levels of global heating was perilously close, and that we are at imminent risk of hitting this threshold in the near term. Guterres is indicated as advising that the only way to prevent exceeding this threshold, is by urgently stepping up our efforts, and pursuing the most ambitious path. Guterres is reported as stating that solutions are clear: "*inclusive and green economies, prosperity, cleaner air and better health are possible for all, if we respond to this crisis with solidarity and courage*". Ahead of the COP26 climate conference in Glasgow in November 2021, Guterres stated that all nations needed to join the net zero emissions coalition, and reinforce their promises on slowing down and reversing global heating "*with credible, concrete, and enhanced Nationally Determined Contributions (NDCs)*" that lay out detailed steps.

31. In April 2022, Guterres tweeted that '*[c]limate activists are sometimes depicted as dangerous radicals. But the truly dangerous radicals are the countries that are increasing the production of fossil fuels. Investing in new fossil fuels infrastructure is moral and economic madness*'.[35] Addressing graduate students in May 2022, Guterres expressed the view that investing in fossil fuels is now "*a dead end* -

[33] Para D.1
[34] https://www.ipcc.ch/2021/08/09/ar6-wg1-20210809-pr/
[35] https://twitter.com/antonioguterres/status/1511294073474367488?lang=en

economically and environmentally. No amount of greenwashing or spin can change that. So, we must put them on notice: Accountability is coming for those who liquidate our future."[36]

32. The 26th Conference of the Parties of the UNFCCC (COP26) was held in Glasgow in the last quarter of 2021. Recognition of the climate 'crisis', as well as the urgent need to increase effort and to accelerate action to address climate change (including by developing nations), are reflected in the outcome of COP26 and recorded in the Glasgow Climate Pact. The Glasgow Climate Pact (among other things):

32.1. Expresses alarm and utmost concern that human activities have caused around 1.1°C of global warming to date and that impacts are already being felt in every region;

32.2. Reaffirms the long-term global goal to hold the increase in the global average temperature to well below 2°C above pre-industrial levels and to pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels, recognizing that this would significantly reduce the risks and impacts of climate change;

32.3. Recognizes that the impacts of climate change will be much lower at the temperature increase of 1.5°C compared with 2°C and resolves to pursue efforts to limit the temperature increase to 1.5°C;

32.4. Recognizes that limiting global warming to 1.5°C requires rapid, deep and sustained reductions in global GHG emissions, including reducing global carbon dioxide emissions by 45 per cent by 2030 relative to the 2010 level and to net zero around mid-century as well as deep reductions in other GHGs;

32.5. Also recognizes that this requires accelerated action in this critical decade, on the basis of the best available scientific knowledge and equity, reflecting common but differentiated responsibilities and respective capabilities and in the context of sustainable development and efforts to eradicate poverty,

32.6. Invites Parties to consider further actions to reduce by 2030 non-carbon dioxide GHG emissions, including methane which has been

[36] https://news.un.org/en/story/2022/05/1118932

JCB

identified as a driver of climate change and the main polluting emission from natural gas;

32.7. Calls upon Parties to accelerate the development, deployment and dissemination of technologies, and the adoption of policies, to transition towards low-emission energy systems, including by rapidly scaling up the deployment of clean power generation and energy efficiency measures, including accelerating efforts towards the phasedown of unabated coal power and phase-out of inefficient fossil fuel subsidies, while providing targeted support to the poorest and most vulnerable in line with national circumstances and recognizing the need for support towards a just transition;

32.8. Emphasizes the importance of protecting, conserving and restoring nature and ecosystems, including forests and other terrestrial and marine ecosystems, to achieve the long-term global goal of the Convention by acting as sinks and reservoirs of GHGs and protecting biodiversity, while ensuring social and environmental safeguards.

33. The climate 'crisis' is also recognised by the International Energy Agency (IEA), of which South Africa is an IEA associated country. During or about July 2021, the IEA published its *Net Zero by 2050 – A Roadmap for the Global Energy Sector* report. In the foreword to this report, the Executive Director of the IEA states (among other things) as follows:

> We are approaching a decisive moment for international efforts to tackle the climate crisis – a great challenge of our times. The number of countries that have pledged to reach net-zero emissions by mid-century or soon after continues to grow, but so do global greenhouse gas emissions. This gap between rhetoric and action needs to close if we are to have a fighting chance of reaching net zero by 2050 and limiting the rise in global temperatures to 1.5 °C.
>
> Doing so requires nothing short of a total transformation of the energy systems that underpin our economies...
>
> Despite the current gap between rhetoric and reality on emissions, our Roadmap shows that there are still pathways to reach net zero by 2050. The one on which we focus is – in

our analysis – the most technically feasible, cost-effective and socially acceptable. Even so, that pathway remains narrow and extremely challenging, requiring all stakeholders – governments, businesses, investors and citizens – to take action this year and every year after so that the goal does not slip out of reach.

This report sets out clear milestones – more than 400 in total, spanning all sectors and technologies – for what needs to happen, and when, to transform the global economy from one dominated by fossil fuels into one powered predominantly by renewable energy like solar and wind. Our pathway requires vast amounts of investment, innovation, skilful policy design and implementation, technology deployment, infrastructure building, international co-operation and efforts across many other areas.

Since the IEA's founding in 1974, one of its core missions has been to promote secure and affordable energy supplies to foster economic growth. This has remained a key concern of our Roadmap, drawing on special analysis carried out with the International Monetary Fund and the International Institute for Applied Systems Analysis. It shows that the enormous challenge of transforming our energy systems is also a huge opportunity for our economies, with the potential to create millions of new jobs and boost economic growth.

Another guiding principle of the Roadmap is that clean energy transitions must be fair and inclusive, leaving nobody behind. We have to ensure that developing economies receive the financing and technological know-how they need to continue building their energy systems to meet the needs of their expanding populations and economies in a sustainable way. It is a moral imperative to bring electricity to the hundreds of millions of people who currently re deprived of access to it, the majority in of them in Africa...

34. On fossil fuels used in energy production, the report states that:

There is no need for investment in new fossil fuel supply in our net zero pathway. Beyond projects already committed as of 2021, there are no new oil and gas fields approved for development in our pathway, and no new coal mines or mine extensions are required.

35. When natural gas is burned for energy, it releases carbon dioxide into the atmosphere. More importantly, the extraction, processing, transport and use of natural gas cause significant amounts of methane to be released into the atmosphere too. *According to the United Nations, **methane is a 84-86 times more potent greenhouse gas than carbon dioxide over a 20-year period, and 28-34 times more potent over 100-***

year period.[37] More research is also showing that methane often leaks during the production, transport and use of natural gas. Therefore, its contribution to climate change is significantly unaccounted for.[38] Drones, laser absorption spectroscopy, and satellites, among other new methane monitoring technologies, have improved the identification and quantification of emissions across the gas lifecycle, leading researchers to conclude that national governments have almost universally underestimated these emissions.[39]

36. If 3,000 megawatts of new gas-to-power plants were built to meet South Africa's 2019 Integrated Resource Plan for Electricity, and the plants were fuelled by imported LNG, the annual emissions from this fuel use would be more than 2.5 million tonnes of CO2e (carbon dioxide equivalent) if the plants ran at 75% capacity. This is the equivalent of driving over half a million gasoline-powered vehicles for a year.[40] For gas or any other fossil fuel, a life-cycle analysis is therefore necessary to quantify the total amounts of GHG emissions (predominantly carbon dioxide and methane) that result from every step in the energy production process: from extracting the fossil fuel at the well or mine to burning it at a power plant or other facility. This is therefore important because all these processes are linked and should not be viewed in isolation.

South Africa's international climate change commitments

37. South Africa is a Party to the United Nations Framework Convention on Climate Change (UNFCCC), which enjoins State Parties to take precautionary measures to anticipate, prevent or minimize the causes of climate change (Article 3.3).

---

See also International Energy Agency, Global Energy Review: CO2 Emissions in 2021,(2022), https://iea.blob.core.windows.net/assets/c3086240-732b-4f6a-89d7-db01be018f5e/GlobalEnergyReviewCO2Emissionsin2021.pdf.

[38] South Africa is likely among those that are underreporting because the Technical Guidelines for GHG reporting uses outdated emission factors from the 2006 Intergovernmental Panel on Climate Change (IPCC) Guidelines

[39] Jonathan Mingle, Methane Detectives: Can a Wave of New Technology Slash Natural Gas Leaks?, YALE E360, (2019), https://e360.yale.edu/features/methane-detectives-can-a-wave-of-new-technology-slash-natural-gas-leaks.

[40] EPA, EPA equivalency calculator, https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator#results

38. South Africa, as a Party to the UNFCCC that ratified the Kyoto Protocol and adopted the Paris Agreement, has committed to *'working with others to ensure temperature increases are kept well below 2°C above pre-industrial levels, which could include a further revision of the temperature goal to below 1.5°C in light of emerging science'* by reducing GHG emissions. South Africa has also committed (among other things) to:

    38.1. Preparing, communicating and maintaining Nationally Determined Contributions (NDCs) that it intends to achieve reach global peaking of GHG emissions as soon as possible, and to undertake rapid reductions thereafter;[41] and

    38.2. Striving to formulate and communicate long-term GHG emission development strategies.[42]

39. There have been various Conferences of the Parties and meetings since, with decisions related to Nationally Determined Contributions (NDCs) contained in decisions 4/CMA.1 and 18/CMA.1 and their annexes.

40. South Africa submitted its first Intended Nationally Determined Contribution under the Paris Agreement on 25 September 2015, which became the country's first NDC on 1 November 2016. Subsequently, South Africa revised its first NDC in 2021:[43]

Table 2 - South Africa's updated NDC mitigation targets

Year	Target	Corresponding period of implementation
2025	South Africa's annual GHG emissions will be in a range from 398-510 Mt CO_2-eq.	2021-2025
2030	South Africa's annual GHG emissions will be in a range from 350-420 Mt CO_2-eq.	2026-2030

[41] Paris Agreement, Article 4.1 – 4.3.

[42] Paris Agreement, Article 4.19

[43] Available online at: https://www.dffe.gov.za/sites/default/files/reports/draftnationallydeterminedcontributions_2021updated.pdf#:~:text=South%20Africa%E2%80%99s%20intended%20nationally%20determined%20contribution%20%28NDC%29%28RSA%2C%20n.d.%29.Agreement%20The%20NDC%20and%20first%20NDC%20are%20identical. This revised NDC is indicated as an enhancement and update of South Africa's NDC under the Paris Agreement, 'meeting its obligation under Article 4.9 to communicate NDC's every 5 years, and responding to requests in paragraphs 23 to 25 of decision 1/CP.21'. South Africa's second (next) NDC is intended to be communicated in 2025.

FC23

41. South Africa's energy sector is estimated at contributing about 84% percent to the country's overall GHG emissions (including Carbon Dioxide and Methane).[44]

42. In February 2020, South Africa submitted to the UNFCCC its first long-term low GHG emission development strategy titled *South Africa's Low Emission Development Strategy 2050*. It is indicated in the executive summary of this strategy that South Africa, as one of the top 20 global GHG emitters and with a high dependency on fossil fuels, will need to make substantial emission cuts to contribute its fair share to global GHG emission reductions.[45]

43. The BAR does not provide any indication (or estimation) of how future GHG emissions (resulting from future exploitation of oil and gas that may be discovered through the exploration drilling project) would impact on South Africa's ability to achieve its GHG emissions targets (as set out in South Africa's NDC) or its updated GHG emissions targets (as set out in South Africa's revised NDC). This is particularly relevant given that the emissions targets for the 2026-2030 period are lower than the targets for the 2021-2025 period, while offshore oil and gas developments could take at least a decade to reach the production stage. This could result in offshore oil and gas investments (as well as associated gas infrastructure developments) in the future becoming unneeded 'stranded assets' and a burden on future generations. There is also a risk that in the future tariffs will be levied on various goods exported by fossil-fuel dependent countries – the European Union is reported to be gradually phasing in its Border Adjustment Mechanism as part of the EU's Green Deal.[46]

Need for seismic data

44. Under the sub-heading 'Need for seismic data', the BAR states that a discussion of the needs and desirability of the project '*would not be complete without understanding*

[44] https://www.climatelinks.org/resources/greenhouse-gas-emissions-factsheet-south-africa

[45] South Africa's Low Emission Development Strategy 2050, pviii.

[46] See for example *Just Energy Transitions and Natural Gas in Africa: Balancing Climate Action and Structural Transformation*, The African Climate Foundation, August 2022, at p14. Available online at: https://africanclimatefoundation.org/wp-content/uploads/2022/10/ACF-GAS-REPORT-V7.indd-final-1.pdf

FL28

the need for acquisition of the seismic data and possible oil and gas exploration and production that could potentially take place in the future as a result of the survey'.[47]

45. Ironically, the BAR then quickly goes on to state that *'[i]t cannot be said with absolute certainty that exploration drilling, let alone production activities, will be undertaken in the future. As such, it is not currently possible to accurately assess the risks associated with these activities, given that the specific details of these potential future activities are not known. While it is acknowledged that the risks mentioned would need assessment, such assessment falls outside of the scope of the current application and would need to be assessed in detail during subsequent Scoping and EIA processes, should exploration drilling or production be proposed. The environmental consequences applicable to the planned survey activities have been identified and assessed in this BA Report'.*[48] The views of the Makhanda High Court in this regard (in the context of future production, climate change and the right to food) have been traversed earlier in the Green Connection and Natural Justice's comments (see paragraphs 27 to 30 above) and are not repeated here. The Green Connection and Natural Justice stands by their view that at the very least a broad assessment of the impacts and risks associated with future invasive exploration activities, production activities and use of any discovered oil reserves should be included in the BAR.

46. The BAR report then proceeds with a glowing (and one-sided) endorsement of the use of natural gas:

> The fastest growing sector for the use of natural gas is for the generation of electric power. Natural gas power plants usually generate electricity in gas turbines, directly using the hot exhaust gases from the combustion of the gas... Of the three fossil fuels used for electric power generation (coal, oil and natural gas), natural gas emits the least carbon dioxide per unit of energy produced. Natural gas emits 30% and 45% less carbon dioxide than burning oil and coal, respectively. Burning natural gas also releases lower amounts of nitrogen oxides, sulphur dioxide, particulates and mercury when compared to coal and oil.
>
> The increased use of natural gas can, in the short term, serve as a transition fuel on the path to the carbon-neutral goal of the Paris Agreement. In addition to gas as a key transitional fuel reducing reliance on coal, the benefits of oil and gas could include

[47] BAR, p33-34.
[48] Ibid.

TCOS

significant amount of job creation, especially if local beneficiation takes place. An increase in domestic natural gas reserves would enable South Africa to take steps to secure the countries' energy supply (through diversification), assist in reducing the emissions of greenhouse gases (by reducing the country's reliance on coal for electricity generation) and reduce the need for the importation of gas. As such, exploration for additional domestic hydrocarbon reserves is considered important and supported by national policy, and any discoveries would be well received by the local market and are consistent with the objectives stated in the 2019 IRP. Natural gas emits 30% and 45% less carbon dioxide than burning oil and coal, respectively, and 65% less carbon dioxide than coal when the increased efficiency of Combined Cycle Gas Turbines versus coal fired power stations is considered. Eskom produces over 200MtCO2/yr, over 40% of South Africa's total. South Africa also has SASOL's Secunda coal to liquids plant, the biggest single source of CO2 in the world at 57MtCO2/yr (~12.5% of South Africa's total) to produce 160k barrels of products per day. Supplying these products from conventional oil production and refining would generate approximately 10% of those emissions, 5 to 6MtCO2/yr.

According to the 2019 IRP the availability of gas in the short to medium term is a risk as South Africa does not currently have gas resources. There is also a supply and foreign exchange risk associated with likely increase in gas volumes depending on the energy mix adopted post 2030 when a large number of coal fired power stations are decommissioned. South Africa's economic growth is dependent on the availability of energy, ensuring a sustainable and reliable supply of electricity with sufficient capacity is a key aspect to growing the economy of South Africa in the future. The electricity shortages experienced in South Africa over the past decade are a contributing factor to the significant slowdown in economic growth rate. To enable economic growth within the target rate of between 5% and 8% to be achieved, it will be necessary for Government to continue increasing electricity generating capacity in the country. The use of natural gas for electricity generation is identified in national policy, together with renewable energy technologies, as an alternative in diversifying the domestic energy supply away from its current reliance on coal. Gas is identified in the draft Integrated Resources Plan as significant contributor to South Africa's energy mix in the period up to 2030. Availability of gas also provides an opportunity to convert to Combined Cycle Gas Turbine and run open-cycle gas turbine plants at Ankerlig (Saldanha Bay), Gourikwa (Mossel Bay), Avon (Outside Durban) and Dedisa (Coega IDZ) on gas (IRP 2019).[49]

47. Perhaps concerned that it is making the case that seismic surveys are indeed the 'thin edge of the wedge' that will lead to increased fossil fuel extraction, production and use

[49] Ibid.

(with associated climate change impacts), the BAR steps back from its natural gas endorsement to repeat the point that *'[f]rom a climate change perspective, it is not currently possible to accurately assess the risks associated with oil and gas activities, given that the specific details of these potential future activities are not known and therefore climate change impacts would need to be assessed in detail during any subsequent Scoping and EIA processes for any potential subsequent oil and gas production projects'*.[50]

48. The BAR then proceeds to argue that:

> The feasibility of using natural gas for domestic power generation is considered to be dependent on the extent of available domestic reserves of natural gas, as well as the financial cost of importing natural gas should those reserves be insufficient. The acquisition of seismic survey data is therefore considered important with respect to understanding the potential for future oil and gas production as part of the energy mix of the country going forward and the need and desirability of the project is therefore supported from an energy security perspective.[51]

49. We note here that despite reliance on the IRP to motivate for the project, the BAR fails to assess whether the amount of gas called for in the IRP would in any event require the exploitation of the resources sought by TGS.

50. Two recent independent studies (among others) challenge the view that fossil gas is necessary for electricity generation and as a transition fuel.

51. The International Institute for Sustainable Development's (IISD) *Gas Pressure: Exploring the case for gas-fired power in South Africa* (March 2022) report points out that while there used to be a rational view that fossil gas would be necessary either during a transition to low-carbon energy or as part of the long-term energy mix for electricity production:

> ....revolutions first in renewable energy costs and then in battery storage costs have upended this view. Analysis of the South African electricity system shows that gas supply is not technically necessary until at least 2035, if ever. In the last few years, either the risks associated with gas have increased, or the understanding of existing risks has increased.

[50] Ibid.
[51] Ibid.

> Consequently, South Africa may see significant negative outcomes from developing a large gas-to-power system now... the trend toward decarbonization, coupled with cost reductions for renewable energy and storage, creates risks for gas investment. Investment in gas can reasonably be expected to lead to higher costs for consumers, just transition challenges for workers, and losses for investors.[52]

52. The ISSD report highlights some of the risks associated with gas-to-power investment in South Africa. These risks include significant contributions to climate change (as a consequence of CO_2 and methane emissions when gas is burned), increasing international pressure to move away from gas due to climate impacts, financial risks linked with gas-to-power, the risk of reduced security of affordable gas supply, the risk of stranded assets, and the risk of creating an additional just transition burden (future gas workers and communities face a repeat of the transition hardships currently faced by the coal sector).[53]

53. Meridian Economics' *'Hot Air about Gas – An Economic Analysis of the Scope and Role for Gas-Fired Power Generation in South Africa'* (June 2022) report points out that while South Africa's large-scale use of gas appears to be central to current energy policy direction in South Africa, *'this rests on a 2012 vision which pre-dates dramatic reductions in renewable energy costs and carbon emissions space'*.[54] The report goes on to state that independent analysis of the power sector across multiple recent studies shows that South Africa's power needs can be met both now and in the future with very little use of gas, and that there is *'no evidence to support the large-scale gas envisaged in the GMP; this is uneconomical even before carbon emissions are considered'*.[55] Meridian point out that *'the assumption that gas-fired power generation would replace coal ignores the fact that other technology combinations are now better at replacing coal-fired power than gas, and it is against these technologies that gas-fired generation should actually be compared'*.[56] Meridian demonstrate that existing modelling provides no economic rationale for "big gas" in the power sector, and that *'the impact of using large volumes of gas to generate power will be borne by electricity*

consumers and will essentially be a subsidy provided by power consumers to otherwise unviable gas use in other sectors'.[57]

54. The Vital Ambition Report[58] by Meridian Economics in collaboration with the Council for Scientific and Industrial Research ("CSIR") Energy Centre ("Vital Ambition Report") states that gas to power is only justified in the South African energy mix in so far as it is required for low-utilisation flexible capacity (peaker plants) for balancing the system during peak power demand. The report confirms that no investments in gas infrastructure for energy production and generation is needed now or in the near future.[59] Furthermore the 2019 IRP will likely need to be updated in the foreseeable future to align with South Africa's 2021 Nationally Determined Contribution under the Paris Agreement and to keep pace with quickly evolving science and significant reductions in price for solar and wind energy. However, even the 2019 IRP, which is rooted in an outdated and scientifically and economically unsound understanding of the necessity for any gas in the energy mix[60], only projects the collective contribution of gas and diesel to the 2030 energy mix to be 1.3% combined.[61]

55. According to a recent report prepared by Robert W. Howarth titled "Methane emissions and climate warming risk from hydraulic fracturing and shale gas development: implications for policy"[62] the climate impacts of gas are greater than those of coal per unit of energy produced when evaluated over a 20-year timeframe, the period most relevant for climate change if humans are to avoid catastrophic run-away warming. Though gas emits less carbon dioxide per unit energy than coal, its upstream GHG emissions are more problematic for the climate, as it leaks and vents potent methane throughout its lifecycle; researchers have been able to better detect emissions across

the lifecycle of gas ever more accurately thanks to new methodologies and technologies (particularly "top-down" measurements using satellite and aerial assessments).

56. The use of fossil fuels must be phased out quickly due to the urgent need to address global warming. A recent study published in *Nature*, the world's leading multidisciplinary science journal, discovered that "by 2050, we find that nearly 60% of oil and fossil methane gas, and 90% of coal, must remain unextracted to stay within a 1.5 °C carbon budget." According to the study, "most regions must reach peak production now or within the next decade, making many operational and planned fossil fuel projects unviable."[63] It is common practice that proposed exploration activities such as reconnaissance, only commence months and sometimes years after the need and desirability assessment is undertaken, with extraction and production only commencing years later.[64] According to one study, the world's largest oil and gas fields took an average of 5.5 years from discovery to first production and 17 years to reach peak output.[65] Chevron Corporation's (CVX) Gorgon natural gas development project off the coast of Australia took 30 years to complete, and another six years to begin producing liquefied natural gas.[66] Therefore exploration projects whose objectives are to locate gas deposits for energy companies to exploit through the construction and production of fossil fuels, run the risk of creating risks for such infrastructure to become stranded assets which invariably impacts on the development potential of South Africa in achieving its climate goals. With no economic justification for large-scale gas use in power, such a strategy would result in assets that are stranded before their first kWh of power is generated. Given this, the proposed reconnaissance project in no way provides a remedy nor will address in the immediate future South Africa's current energy insecurity issues.

(https://www.sciencedirect.com/science/article/pii/S2666278720300106

[66] https://australia.chevron.com/-/media/australia/our-businesses/documents/Gorgon-Project-Milestones-Fact-Sheet.pdf

OLDS

57. Importantly, seismic surveys to explore for oil and gas will not have any immediate impact on South Africa's energy security, as any oil and gas extracted would not belong to South Africa, but would invariably belong to the companies that extract for profit.[67] Energy companies compete for access to mineral rights granted by governments by either entering a concession agreement, meaning any discovered oil and gas are the property of the producers, or form part of a production-sharing agreement which favours the interest of the producers and ultimately diminishing the general interests of the broader South African Republic.

58. The oil and gas that will be eventually extracted by oil and gas companies is ultimately exploited for profit. It is not used to generate a benefit that results in broad based security for energy production nor does it lead to the production of energy for South Africa and its citizens. If oil and gas found following a successful reconnaissance, and that are ultimately exploited, are not used to produce energy for South Africa, this invariably undermines the sole stated goal underpinning the need and desirability of this proposed reconnaissance project—its supposed contribution to energy security for South Africa—and provides no tangible benefit for South Africans.

59. While the increased use of gas as a 'transitional fuel' is promoted by government and vested interest groups, the Green Connection and Natural Justice submit that the increased use of fossil gas (especially in electricity generation) will lead to increased emissions of climate warming GHGs, and methane (CH_4) in particular. While natural gas combustion is less carbon-intensive than that of coal, fugitive emissions arising from the production, transport, storage and use of natural gas have a much greater climate impact than CO_2. In particular, over a 20-year period (which is particularly relevant since the next 20 years are a critical window for addressing the climate crisis) methane emissions, which make up approximately 70-90% of natural gas emissions, are projected to be 82.5 times as impactful as those of CO_2.[68] The desirability of using gas as a 'transitional' fuel is also questionable having regard to volatile international gas prices, as well as the potential risk of Carbon Border Taxes being introduced in

[67] Stewart Glickman and Shang Yang Chuah, Oil, Gas & Consumable Fuels Industry Survey (New York: CFRA, 2019)

[68] See the IPCC's 6th Assessment Report (AR6), Working Group 1, Chapter 6 *The Earth's Energy Budget, Climate Feedbacks and Climate Sensitivity*, Table 7.15 at p1017 Available online at: https://www.ipcc.ch/report/ar6/wg1/downloads/report/IPCC_AR6_WGI_Chapter07.pdf

the future.[69] This risk will impose restrictions on the export of products with a high carbon footprint, putting South Africa's economy at greater risk of developing gas to power rather than clean renewable alternatives. This invariably diminishes the need and desirability for promoting new gas development projects, as the negative climate impacts and financial risks undermine the potential for gas to represent a viable solution for South Africa's ambitions to address development whilst respecting universal and regional climate change obligations.

60. The fundamental outcome of the need and desirability assessment should not be centred on the determination of whether gas technology will ensure security of supply for electricity. Instead, due to the climate crisis, this assessment should be centred on whether South Africa needs, or should rely on, gas to provide security of supply of electricity and whether alternative technologies could meet the same supply objectives with less harm and risk. Renewable energy and/or storage can replace gas to provide reliable and cost-effective generating capacity while greatly reducing the environmental and health risks associated with gas.[70]

61. The call for gas as part of the energy mix set forth in the 2019 IRP does not excuse the decision-maker from taking climate change impacts into account, including as part of the need and desirability assessment. The case for need and desirability must address climate impacts and cannot simply rest on the 2019 IRP as evidence of need or desirability as relied upon by the EAP in the BAR. In the judgment of the High Court in *Earthlife Africa*[71], the court expressed that with respect to a decision maker's reliance on the IRP when rendering a decision on an application for environmental authorisation, the following is important to acknowledge:

(a) "Policy instruments developed by the Department of Energy cannot alter the requirements of environmental legislation for relevant climate change factors to be considered".[72]

[72] See above at para 97.

5628

(b) Establishing the need and desirability of a proposed project, is a key objective of each stage of scoping and impact assessment and must account for South Africa's 2021 NDC under the Paris Agreement. The EAP must therefore provide a broad and robust analysis of multiple alternative literature on renewable energy resources and make a justifiable and reasonable case for a project's need and desirability having considered the available literature, without relying solely on the 2019 IRP and other policy documents. This invariably assists the decision maker to prioritise the granting of the best decision which will prioritize the integrity of the environment, and the social welfare, health and safety aspects of the socio-economic environment for present and future generations.

Ground 2: Failure to adequately consider marine impacts.

Underwater sound from seismic surveys

62. The ocean is an acoustic world. This is because water is a dense medium, and sound travels faster and farther underwater. Marine species, from larvae to whales, utilise this efficiency and have evolved to depend on sound for essential biological functions, including feeding, breeding, communicating, navigating, and socializing.[73]

63. Sound is also a fundamental component of marine habitats. Different ocean environments have distinct acoustic signatures that comprise their acoustic habitat. These acoustic habitats are created from a combination of biological sounds (e.g., fish choruses, snapping shrimp, urchin movement, whale calls) and environmental sounds (e.g. waves crashing, rain, earthquakes). The addition of anthropogenic noise to these

---

[73] Supporting Affidavit of Dr. Aaron N. Rice at paras. 8, *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, attached marked Annex B1; Supporting Affidavit of Dr. Douglas P. Nowacek at paras. 9 & 13, *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021, attached marked Annex B2.

This appeal incorporates the expert opinions of Dr. Rice and Dr. Nowacek who submitted affidavits in the matter of *Sustaining the Wild Coast NPC & Others v Minister of Mineral Resources and Energy & Others*, High Court of South Africa, Eastern Cape Division, Makhanda – Case No. 3491/2021. Both of the affidavits provide expert insight on underwater acoustics, how marine species utilize acoustic cues for biological processes, and how seismic surveys may impact different taxa. The declarations will be used to assist the court to understand general principles and processes and will not be used to support specific impacts that were associated with that case on the east coast of South Africa.

soundscapes disrupts the abilities of marine species to use naturally occurring acoustic cues and has detrimental effects on individual organisms, populations, and communities. [74]

64. Seismic airgun blast are the loudest human-created noises introduced into the ocean environment and they travel long distances through seawater. Studies have shown that seismic blasts are at least detectable at distances greater than 500-700 km, even up to 4,000 km.[75] Other studies have detected seismic surveys at levels sufficient to mask, or obscure, baleen whale calls at distances of thousands of kilometres away from the source.[76] Airgun noise influences and degrades the acoustic habitat of marine species over a far greater area than the metres and kilometres that the FBAR considers and in fact, according to the science, can easily reach coastal areas 120 – 230 km from the survey area.

65. In addition, the noise produced by airgun arrays becomes virtually continuous at greater distances from the source creating chronic noise impacts. This is because the sounds emanating from a seismic airgun array do not behave as individual and finite sound source *in situ* but reflect off the ocean surface and seafloor as they travel, leading to a continuous increase in the sound level through reverberation. The effect has repeatedly been documented.[77] Studies have found seismic surveys causing elevated ambient noise levels by more than 25 dB (approximately a 4-fold increase in noise levels) across distances of 40 km and these sound levels remain elevated during the periods between airgun blasts.[78] Open ocean condition observations have found that the noise produced and were sustained for months at a time.[79]

66. Because of several flaws in its approach, the BAR does not fully identify and assess the risk posed to marine species and ecosystems and does not effectively mitigate the risks from the proposed the proposed surveying.

Harms to marine life

---

[76] Rice Supporting Affidavit at para. 18; Nowacek Supporting Affidavit at paras. 13.
[77] Rice Supporting Affidavit at para. 19-20; Nowacek Supporting Affidavit at para. 10.
[78] Rice Supporting Affidavit at para. 19-20; Nowacek Supporting Affidavit at para. 10.
[79] Rice Supporting Affidavit at para. 19-20; Nowacek Supporting Affidavit at para. 10.

67. It is well established that marine seismic surveys cause serious and irreparable harms to marine life. The Biodiversity and Ecosystem Services Assessment Report[39] ("Pisces Report") prepared for the Project acknowledges the a wide range of impacts on numerous species:

- Physiological injury and/or mortality;
- Behavioural avoidance;
- Reduced reproductive success/spawning;
- Masking of environmental sounds and communication;
- Collision of turtles/marine mammals with the survey and support vessels or entanglement in towed acoustic apparatus; and
- Indirect impacts on piscivorous predators due to seismic effects on prey species.

68. According to the Pisces Report, the following species are present in the Project area and face the highest risk of harm from the proposed survey:

- humpback whales, which migrate through the area between June and November (inclusive);
- sperm whales, beaked whales and other odontocetes that frequent offshore waters;
- large migratory pelagic fish and shark species that show seasonal association with Child's Bank and Tripp Seamount;
- leatherback turtles which frequent offshore waters in low numbers and aggregate around seamounts to feed on jellyfish; and
- various pelagic Albatross, Petrel, Storm Petrel and Shearwater species (the Pisces report indicates that pelagic seabirds are likely to be relatively frequently encountered in the offshore waters of the Reconnaissance Permit area).[41]

[39] PISCES Environmental Svcs (Pty) Ltd (for TGS Geophysical Company), *Biodiversity and Ecosystem Services Assessment Report* ("Pisces Report") (Sept. 2022).
[41] Pisces Report at 45.

69. A 2022 review of peer-reviewed literature on the physiological, behavioural and ecological impacts of the 3D seismic survey activities on marine wildlife[42] ("Harris Report", attached marked **Annex B3**) found that the type of sound emitted during seismic surveys has been directly linked to physical damage to marine animals, including soft tissue trauma damage, embolisms, damage to organs used in balance and orientation, concussions, haemorrhaging, decompression sickness and both temporary and permanent threshold shifts to hearing ability. The Harris Report also found that some species display physiological stress responses and behavioural changes to seismic activities, such as moving away rapidly, diving or remaining still. These responses are likely to increase their energy consumption and energy costs, reduce their time to forage, and/or affect their vulnerability to predation, thus having negative impacts on the survival of individuals (especially young or compromised animals) as well as the overall population growth and survival of a species (especially for threatened species that are already at risk of extinction).

Acoustic Modelling

70. The Appellants submit that the underwater noise modelling was largely a desktop study rather than a meaningful examination of the acoustic harms that seismic surveying will have.

71. The acoustic modelling failed to provide meaningful information in several ways:

    71.1. The model should have included in situ testing to 'ground truth' the modelling and accurately determine the potential noise impacts associated with various aspects of the proposed 3D seismic survey (sound in the ocean is affected by pressure, salinity, temperature and temperature gradients, and can travel many kilometres from the source).

    71.2. The model should have assessed the impacts of noise on all species (different species have different sensitivities to noise) during the environmental impact assessment process (not ex post factor).

    71.3. The assessment should include (but not be limited to) potential impacts on the migration of snoek (a species that is important to the

[42] Harris, Gilbert & Wright, *Report on Scientific Basis for concerns of significant harm inflicted to marine wildlife by 2D and 3D seismic surveys on the South and West Coasts of South Africa* (14 January 2022).

livelihoods of small-scale fishers) and juvenile turtles (which are significant from a biodiversity perspective given their endangered status) that are in turn dependent on other species.

Heightened Legislative Requirements are Not Considered for Critical Biodiversity Areas (CBAs), Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs)

72. The National Environmental Management: Biodiversity Act, 2004 ("NEMBA") provides for ecosystems that warrant special conservation attention. These include ecosystems identified as Critical Biodiversity Areas ("CBAs") or Ecological Support Areas ("ESAs") in a bioregional plan, biodiversity sector plan or provincial spatial biodiversity plan.

73. The Appellants contend that the Minister ignored the critical importance of NEM:BA, NEM:PAA and relevant provisions of NEM:ICMA in terms of protecting and conserving the identified CBAs within the survey area, as well as the EBSAs and MPAs. At the very least, the value of these areas and the extent of potential negative impacts of exploratory activities on these areas should have been considered. The BAR failed to provide any assessments for the CBAs contained within the Application Area or the EBSAs and MPAs that are adjacent to the area.

CBAs

74. The FBAR failed to meet even minimal standards of providing a "detailed assessment" and relevant mitigation in order to protect irreplaceable and near-irreplaceable CBAs from the intense and chronic blasts of the seismic survey. In fact, the Sound Transmission Loss Modelling report makes no reference to critical biodiversity areas.

75. FBAR acknowledges that there are several CBAs within the Application Area itself:

> *The Application Area overlaps with areas mapped as Critical Biodiversity Area 1 (CBA 1): Natural and Critical Biodiversity Area 2: (CBA 2) Natural. Approximately 32.25 % of the proposed 3D acquisition area is covered by CBA 1 and CBA 2 Natural, 0.22% by CBA 1 and CBA 2 Restore, and 1.75% by ESA (see Figure 91).*[83]

[83] BAR at 162.

76. CBA 1 are irreplaceable or near-irreplaceable sites that are "required to meet biodiversity targets with limited, if any options to meet targets elsewhere."[84] CBA 2 are best design sites where there may be alternative areas where biodiversity targets can be met at a higher cost or requiring the allocation of additional area to achieve the targets.[85]

77. The FBAR recognizes that the exploration activities, including seismic surveys, are classified as having restricted compatibility with CBAs, which require a "detailed assessment to determine whether the recommendation is that they should be permitted (general – as is the case for this assessment), permitted subject to additional regulations (consent), or prohibited, depending on a variety of factors."[86] The BAR fails to even identify the unique and irreplaceable features of the CBAs in order to be able to assess whether this activity should be permitted.

78. CBA areas have been identified and set aside, and resources have been invested, in order to protect these biologically critical habitats and the marine species that depend on them. Seismic surveys will run directly over these critical biodiversity areas designated as irreplaceable and near-irreplaceable, causing severe and potentially irreversible impacts.

79. The FBAR has failed to look in detail at the CBAs, understanding why they were identified as critical biodiversity areas, and then propose specific mitigation measures in order to make an informed assessment as to the "restricted capability."

<u>EBSAs and MPAs</u>

80. The underwater Sound Transmission Loss Modelling report conducted for the BAR indicates in its introduction that the proposed survey areas are adjacent to a few Ecologically or Biologically Significant Marine Areas (EBSAs), and Marine Protected Areas (MPAs) including Childs Bank and Shelf Edge, and Cape Canyon and Associated Islands, Bays and Lagoon.[87] The BAR expands that list adding important areas such as the Benguela Muds MPA, Robben Island MPA, Southeast Atlantic

[84] BAR at 162.
[85] BAR at 162.
[86] BAR at 162.
[87] TGS: South Africa Orange Basin 3D Seismic Survey, Sound Transmission Loss Modelling at at 1-2

Seamounts MPA and additional MPAs "that fall within the broader project area."[88] The Bar also identifies and describes eight EBSAs, including transboundary relevant to the seismic survey area.[89]

81. Although these protected areas do not fall within the seismic survey area itself, the nature of seismic survey will cause impacts on the habitats and the marine species that these areas are meant to protect. These include endangered and protected species, breeding areas, sensitive and vulnerable habitat, resident whales, and many other features which make the spaces fragile and sometimes slow to recover, which has warranted their protection.

82. The FBAR makes no effort to identify impacts to these sensitive areas and to mitigate the potentially irreversible harms that the seismic survey will cause. As noted above, the sound from seismic surveys can travel hundreds of kilometres and will penetrate into the MPAs and EBSAs. Further, the seismic surveys will increase the ambient noise beyond the survery area. The chronic blasting every 6-20 seconds for months (70 days) will cause behavioural disturbances and possibly more damage to these sensitive areas, which the BAR did not take into account.

Cape fur seals

83. In South Africa, since October 2021, thousands of dead and/or dying Cape fur seals, have washed ashore along the south and west coasts. The cause of these die-offs remains unknown but avian flu has been ruled out and malnourishment appears to be the most widely accepted reason. Activities associated with the Project could further pressure this species by physically harming individual seals, and by disrupting the seals' food supply.

84. The Pisces Report states that Cape fur seals are unlikely to be found in the project area, citing map that shows generalized foraging areas that extend nearly exactly to the edge of the reconnaissance area.[90] However, the report also states, "[s]eals are highly mobile animals with a general foraging area covering the continental shelf up to 120 nautical miles (~220 km) offshore,"[91] meaning a large part of the

[88] BAR at 157-59.
[89] BAR at 159-61.
[90] Pisces Report at 69 (Fig. 37).
[91] *Id.* at 111.

FL28

reconnaissance area is well within the foraging range of Cape fur seals. Moreover, the Based on the questionable assumption that Cape fur seals are unlikely to occur within the reconnaissance area, the Pisces Report authors deemed their sensitivity to the proposed seismic operations to be "LOW," in spite of the finding that "The potential impact of physiological injury to seals as a result of seismic noise is deemed to be of HIGH intensity."[92]

Whales and dolphins

85. There is genuine conservation concern for beaked whales that are particularly sensitive to anthropogenic noise, including seismic surveys. It has been demonstrated that even minor, non-lethal disturbances, resulting in changes in behaviour such as displacement from preferred habitats, could impact a population.[93]

86. The phenomenon of energy-cost (from stress and avoidance behaviour) is of particular concern for some of the species expected to be encountered in the survey area in question, particularly the humpback whales and southern right whales who are at risk of the airgun noise affecting their behaviour or interfering with the communication between mother and calf. Any impact on their energy reserves could impact on their condition (weight-loss and physiological condition) and affect survival of the animals during a vulnerable time (especially for lactating mothers and their calves) on their long migration to feeding grounds in Antarctica.[94]

Fish

87. The BAR downplays the impacts of seismic surveys on fish and the fisheries they support, particularly in the case of the large pelagic longline fishery and the tuna pole-line fishery. While the BAR assesses the exclusion of fishing vessels due to temporary safety zones during seismic surveys, it fails to adequately assess the actual impacts of seismic activities on the target fish species themselves, both in the short and long-term. During the seismic survey, fishing vessels would be required to maintain a safe operational distance from the survey vessel and streamer array, which may extend up to 6 nautical miles. The FBAR assessed the impact of potential

[92] *Id.*
[93] Harris Report
[94] Harris Report

exclusion for each commercial sector based on the affected area of fishing ground and the amount of catch reported within the Reconnaissance Permit area. Given the location of the Reconnaissance Permit application area, two high-value fisheries are directly impacted: the large pelagic longline fishery (targeting tuna, swordfish and shark) and the tuna pole-line fishery.

88. The FBAR concluded that the Project's activities will result in exclusion to fishing grounds for at least the large pelagic longline fishery. The FBAR states that "[t]here is a high probability that the large pelagic longline sector (targeting tuna, swordfish and shark) will experience loss of access to fishing ground over the duration of the proposed 70-day survey," and that [t]he impact of exclusion is assessed to be of high magnitude."[95]

89. In terms of noise impacts to the target fish of the large pelagic longline fishery and the tuna pole-line fishery, the Pisces Report acknowledges that "[s]eismic activities have been predicted to possibly affect the migration patterns of tuna leading to substantially reduced catches of albacore and southern bluefin tuna in southern Namibia and the Great Australian Bight, respectively,"[96] yet ultimately the Report concludes that "[a]s there is currently a dearth of information on the impacts of seismic noise on truly pelagic species such as swordfish and tuna (Evans et al. 2018; Webster et al. 2018), links between changes in migration patterns and subsequent catches thus remains speculative."[97] The FBAR thus maintains that potential impact on individual fish behaviour is of MEDIUM consequence and that "the residual impact due to seismic noise is considered to be of LOW NEGATIVE significance for the large pelagic longline and tuna pole-line sectors."[98]

90. Overall, the FBAR concludes that with mitigation (timing of the surveys to avoid peak fishing periods), the following overall impact significance:

> Based on the combination of extent, duration and magnitude of the impact, and considering the high probability that the impact would occur, the overall

[95] BAR, pg. 212.
[96] Pisces Report, pg. 132.
[97] Pisces Report, pg. 132.
[98] BAR, pg. 244.

JG28

> significance of the impact is considered to be MEDIUM NEGATIVE. Due to the low probability of the operations of the tuna pole-line sector within the Reconnaissance Permit area, the overall significance of the impact on the sector is considered to be LOW NEGATIVE.

91. The FBAR fails to adequately assess the vulnerability of the targeted fish species (including tuna and sharks) to noise impacts, and any decision-based on it would be unreasonable. This is a major flaw because many of the large pelagic fish and shark species likely to occur in the offshore regions of the Orange Basin are considered globally 'Vulnerable' (e.g., bigeye tuna, blue marlin, Oceanic Whitetip shark, dusky shark, great white shark, longfin mako), 'Endangered' (e.g., shortfin mako, whale shark) and 'Critically Endangered' (Southern bluefin tuna).

92. The impact on fish assemblages is difficult to interpret, due to multiple factors at play including but not limited to the ability of a species to move from an area as well as the receiving habitat. A global review of the effect of seismic activities on fish and invertebrates acknowledged the limits of the current research due to experimental designs used or due to the focus on single species during investigations. A key concern is a lack of research focused on confounding effects and multiple stressors, therefore potential impacts of seismic surveys that have been previously identified may be reflective of underestimation or overestimation and would depend on the type of interaction (synergistic, additive, or antagonistic).[99]

93. Sounds pollution from seismic surveys may have a wide range of effects on fish species. Exposure to intense sounds can result in mortal injury, but over longer distances issues are associated with sounds that are detectable by fish and which may affect their behaviour, causing them to move away from their migration routes, flee important habitats in which they feed or breed, interfere with their communications, affect reproductive behaviour (where sound is used to attract mates and facilitate spawning), or prevent or mask the detection of other biologically important sounds. Because of these many-pronged effects, seismic surveys can have compounding negative impacts on marine fish.

[99] Harris Report

FLDS

94. In his expert affidavit filed in a recent seismic survey case,[100] Dr Alexander Claus Winkler provided testimony regarding evidence of direct, lasting behavioural effects of seismic surveys on the rhythmic behavioural foraging patterns of cod in the North Sea. Winkler points out that both hake and snoek perform rhythmic diel foraging migrations off the seafloor at night and onto the seabed during the day. Given that seismic surveys are conducted both during the day and night, it is likely that these benthic fish species will migrate higher up the water column at night, bringing them within distances that may expose them to direct injury and mortality impacts from seismic surveys. It is noted that the Pisces report indicates that species most likely to be found in the area of interest include large migratory fish (such as tuna, billfish and sharks), many of which are considered threatened by the IUCN due to overfishing.[101]

95. In addition, contrary to the FBAR's conclusions that there is only LOW NEGATIVE significance for the large pelagic longline and tuna pole-line sectors,[102] a 2018 desktop survey of South Africa fisheries impacts from seismic surveying by Namibian fisheries expert David Russell ("Russell Report") concluded the following:

> [W]here there are cumulative impacts from repetitive surveys in the same area, as has occurred off Southern Namibia tuna fishing grounds, where catches have severely declined since 2011, and in 2017 dropped off to non-commercial catch rates, there is the ominous possibility that the tunas change their migration path. Environmental factors such as El Nino appear to also have contributed significantly, but combined with regular seismic surveys, the environmental signals are potentially devastating.[103]

96. There is a possibility that up to three seismic surveys (Searcher, TGS, and GX Technologies) would take place simultaneously in the area, which would further increase geographic exclusion of the fishery. If multiple 3D seismic surveys were not undertaken simultaneously, then sequential surveys in the same area would prolong the loss of access to the pelagic longline sector and duration of seismic impacts to

[100] Available online at: https://drive.google.com/drive/folders/1m-h8MoRtdfUKHLiB_ulD1KX-dBktua [21. Alexander Winkler].

[103] Assessing the Impact of Seismic Surveys on South African Fisheries, 2018. David Russell Fisheries Consultancy for the Responsible Fisheries Alliance ("Russell Report"), pg. 6.

fisheries. Yet the FBAR does not directly assess the impacts of simultaneous surveys on the fisheries.

97. The FBAR concludes, without citing any evidence, that after months of up to three simultaneous seismic surveys in the pelagic longline sector, "[o]nce completed there is not expected to be any residual impact."[104] As noted above, the Russell report identified potential long-term impacts of repeat seismic activity on Southern Namibian tuna fisheries, with implications that tuna may change their migration patterns to avoid noise pollution.[105] The BAR fails to adequately consider or mitigate impacts to the pelagic longline sector that are both short-term (potentially closing the fishery for 70 days or longer given multiple surveys in a single year) and long-term (inflicting behavioural and migration shifts).

98. The sector had an estimated wholesale value of R124 Million in 2018, or 1.2% of the total value of all fisheries combined. For tuna pole-line, the fishery runs predominantly from November through June, while the large pelagic longline fishery runs highest from May to November.[106] The FBAR lists a proposed window of January – May for its 70-day 3D seismic survey, meaning a large fraction (up to 30% with an approximate wholesale value of R40 Million) of the fishery year stands to be excluded. Because its assessment did not adequately consider the longer-term residual impacts on the fisheries from seismic activity, this monetary loss stands to be much greater than that estimated from fishery exclusion alone.

99. The FBAR fails to consider the long-term behavioural or migration impacts that seismic activity could have on the pelagic longline fishery, which include several species of tuna. Such changes in the fishery could have severe and lasting implications for communities dependent on this important fishery for many years to come and should have been included in the impact assessment.

---

[105] Russell Report.

[106] BAR App. 3.2 PROPOSED 3D MULTI-CLIENT SEISMIC SURVEY IN THE ORANGE BASIN, OFFSHORE SOUTH AFRICA Fisheries Specialist Study, September 2022 ("Capricorn Report"), pg. 66.

100. The FBAR states that "[t]he zones of TTS [temporary threshold shift] effect for fish species with and without swim bladders are predicted to be within 3.5 km from the survey lines for the 3D survey 24-hour operation scenarios considered."[107] This predicted zone of TTS for fish both with and without swim bladders is a gross underestimation and based on minimal and non-regional specific data, including data from riverine 2D seismic activity on freshwater species (e.g. Popper et al., 2005). As the Capricorn Report admits, "[t]o date there have been no studies focused directly on the [fish] species found locally."[108]

101. Most of the mitigation measures proposed in the BAR are designed to minimise impacts to marine mammals. As admitted in the Pisces Report, vastly less is known about how such mitigation measures alleviate sound impacts experienced by marine fish species.[109] Large pelagic fish (e.g. tuna, sunfish, or sharks) would not be detected by PAM (which would be tuned for marine mammal vocalisations) and would not likely be detected visually at night by observers or using an infrared thermal imaging camera (since cold-blooded fish, as opposed to warm-blooded mammals, do not have high enough temperature differences from the water).

102. The FBAR further fails to provide evidence that infrared thermal imaging is effective as a mitigation measure.

103. TGS takes no preventative mitigation measures to minimise impacts to marine fish species during 3D surveying and has a single and insignificant mitigation measure (7.1) to shut down seismic shooting in the case the following is observed: "mass mortalities of squid and fish (specifically large shoals of tuna or surface shoaling small pelagic species such as sardine, anchovy and mackerel) when estimated by the MMO [marine mammal observer] to be as a direct result of the survey."[110]

104. Although it has been suggested that the sound energy from air guns may harm fish species with swim bladders and those without, there are very few studies directly

[107] BAR, pg. 235.
[108] Capricorn Report, pg. 10.
[109] PISCES Report, pg. 192.
[110] PISCES Report, pg. 197.

examining the potential effects on fish physiology or behaviour, and even fewer focusing on pelagic fish species. Unknown impacts are not the same as no impacts, and the precautionary principle should be invoked. There are significant knowledge gaps regarding the impact of 3D seismic surveys on marine fish species, particularly those that would be impacted by the Project. Specifically, there is currently not enough information about the fish species in the area or their response to sound to be able to make any meaningful assessment of the impacts. Therefore, the precautionary approach set out in NEMA suggests that this lack of knowledge should weigh against the proposed 3D seismic surveying in a vital and valuable offshore fishery.

Zooplankton

105. The FBAR disregards the precautionary approach at every step in the analysis of impacts on plankton, which it concludes does not warrant mitigation measures and will have a medium pre-mitigation impact, yet a very low residual impact.[111] Yet, as demonstrated below, there is a significant concern that the BAR underestimates the impacts of seismic surveys on plankton, which form the base of the ocean food chain.

106. The FBAR does not provide actual data to demonstrate that there is not significant or even medium plankton abundance in the survey area. The BAR "expects" that plankton abundance to be low with seasonal peaks may occur associate with MPAs.[112] Yet, the surveying is meant to have temporal overlap with speak spawning products of commercially important species.[113]

107. Studies by McCauley et al. (2017) referenced in the Pisces Report indicates that seismic blasts may kill various species of zooplankton in Australia at distances of up to 1200 m from an airgun[114], and more recent research shows lethal and behavioral impacts to zooplankton from airgun discharges.[115] Still, other studies (Fields et al.,

[111] Marine Ecology Impact Assessment at 144.
[112] Marine Ecology Impact Assessment at 141.
[113] Marine Ecology Impact Assessment at 144.
[114] Robert D. McCauley *et al., Widely used marine seismic survey air gun operations negatively impact zooplankton*, 1, Nat. Ecol. Evol., 1–8 (2017).

5608

2019), report no measured mortality or sublethal effect on copepods at distances >10 m from a seismic blast in Norwegian waters.[116] And other studies (Richardson 2017) found "substantial impact of seismic activity on zooplankton populations on a local scale within or close to the survey area."[117] While noting that zooplankton mortality can be difficult to assess in the field (in situ) and that realistic conditions are very difficult to reproduce in a laboratory setting, nevertheless these highly contradictory results suggest that effects may be variable and highly dependent on zooplankton species and/or marine geographical area. Research should be undertaken to survey the current literature on zooplankton types in the Benguela Upwelling Zone and better link this knowledge to the airgun impacts literature available. The BAR fails to take these steps, making it impossible to assess the impacts of seismic surveys to the zooplankton communities underpinning the food webs that support fish, marine mammals, and fisheries.

108. As noted, zooplankton forms the base of many important food webs in the marine environment. Depletion of zooplankton could thus have an impact on food for their predators (such as fish) as well as impact fish eggs and larvae (ichthyoplankton) with potential local impacts on species important in fisheries. This damage to zooplankton as found by studies over 1km away (McCauley 2017) and within 15km (Richardson 2017) from the survey array raises concern that a 500m buffer for other animals that are unable to move away from the sound, is far too small to ensure that damage is not inflicted (even if they were able to evade it).[118]

The proposed mitigation measures are inadequate to prevent unacceptable harm to marine life

<u>Simultaneous Surveys</u>

109. The BAR proposes the use of a 40 km buffer between vessels during concurrent simultaneous surveys (p. 211) as a mitigation measure, relying on "advice from the US Department of Interior (2014)." The purpose of the buffer is to mitigate "the

---

[116] *Id.*

[117] Rios Supporting Expert Affidavit at para. 29 (restating the conclusion from the study's authors: "We found there was substantial impact of seismic activity on zooplankton populations on a local scale within or close to the survey area, with a maximum decline of 22% in zooplankton populations in the survey area, 14% within 15 km of the survey area.").

[118] Harris Report

cumulative impacts of three potential surveys occurring concurrently."[119] The 40 km buffer mitigation measure, first proposed in the United States, originally purported to avoid harassment of marine mammals during simultaneous surveys. This was expected to be achieved through a distance between vessels that would provide a corridor where "airgun noise is below [harassment] thresholds and approaching ambient levels such that animals may pass through rather than go larger distances to go around the survey vessels."[120] However, the mitigation measure neither provides a corridor below harassing levels of acoustic noise for marine mammals between vessels seismic surveying, nor does it mitigate cumulative impacts as portrayed in the FBAR. In fact, the mitigation measure is not even used in the US, making the FBAR reliance upon this measure deeply flawed.

110. First, the 40 km buffer is based upon a threshold of 160 dB for harassment, a standard that the U.S. government has since abandoned as appropriate to provide adequate protections. For example, the US government found in 2018 in reviewing harms to marine mammals during oil and gas geophysical surveys that, "[s]tudies of marine mammals in the wild and in experimental settings do not support" use of a single 160-decibel threshold and that "that an approach reflecting a more complex probabilistic function is better reflective of available scientific information," because it "takes the fundamental step of acknowledging the potential for . . . harassment at exposures to received levels below 160 [decibels]."[121]

111. Second, as noted above, scientists recognize that this 160 decibel threshold is not supported by science. In addition, in his expert declaration Dr. Nowacek noted that "seismic surveys can disrupt important behaviors in baleen whales at exposure levels far below the 160 dB threshold".[122]

112. Third, the application of a 40 km buffer as a wholesale solution for simultaneous surveys is incompatible with even the 2014 Department of Interior document that the BAR is relying upon. In fact, the US Government prohibits the use of a 40 km buffer

[119] BAR at 211.

[121] See Taking and Importing Marine Mammals; Taking Marine Mammals Incidental to Geophysical Surveys Related to Oil and Gas Activities in the Gulf of Mexico, 83 Fed. Reg. 29,212, 29,247-48 (June 22, 2018).
[122] See Nowacek Supporting Affidavit at para. 18.

JCJS

as a general mitigation measure. It instead found that new science demonstrated that "airgun noise can be detected at great distances from the sound source, such as across ocean basins," and that therefore, the mitigation measure must be considered in the site-specific context and include any new information at the time as well as "any potential aggregate effects from existing permitted surveys."[123] The BAR does none of this analysis and in fact proposes potentially reducing the buffer zone.[124]

113. This mitigation measure has been proven to be scientifically unsound and ineffective and uses an approach inapposite with the base documents upon which the BAR relies, inconsistent with the current practice of the US Government, and inconsistent with the science. Therefore, there is no basis for the BAR to conclude that a 40 km buffer will mitigate cumulative impacts of concurrent seismic surveys.

Inefficacy of Proposed Mitigation Measures

114. Several of the proposed mitigation measures are ineffective to mitigate the harms related to the impacts of the seismic surveys. Consequently, the significance of the post mitigation impacts are understated, exposing marine species, in particular marine mammals and to more injury and harm than indicated in the conclusions of the BAR.

115. Soft Starts and Ramp Ups: Harris *et al.* found that the soft starts are "are likely to reduce the impact for highly mobile large animals, this is unlikely to be adequate for the many species that are prevalent in the area over the austral summer months and are unable to avoid the array or leave the area due to their lower mobility, such as smaller turtles, penguins, invertebrates, some fish species and zooplankton."[125] Moreso, Dr. Nowacek found that soft starts or ramp ups do not protect highly mobile cataceans, finding them "inadequate to protect cetaceans present year-round or deep-diving beaked whales."[126] Dr. Nowacek further expounded "there has been no experimental confirmation that this procedure is broadly effective at reducing overall exposure."[127] In considering a situation where soft starts or ramp ups worked perfectly, Dr. Nowacek found that "this mitigation measure would reduce only the number of

SLB

injuries incurred in the vicinity of the seismic vessel and does not address at all the larger body of effects."[128]

116. Observers: Harris *et al.* explain that visual observers, although important to mitigation, have deficiencies, which brings into question the BAR's conclusions regarding the level of impacts post-mitigation:

> *"The finding of observer efficiency (from a scientific monitoring study conducted during the 2018/19 and 2019/2020 seasons on the humpback whales on the east coast) suggests that even with trained observers up to 44% of humpback whales in an area went undetected. This casts doubt on the effectiveness and success of Marine Mammal Observer (MMO) sightings of the largest species (humpbacks) as a mitigation measure, indicating that it is most likely that whales go undetected. Furthermore, the detection rate for smaller species, such as dolphins, seals, turtles and flightless birds (penguins), would be expected to be much lower, obviating the effectiveness of visual observations to prevent harm to these species."*[129]

117. Dr. Nowacek reiterates that the mitigation measure of visual observers is "inadequate to protect cetaceans present year-round or deep-diving beaked whales."[130] Dr. Nowacek further explains that the use of visual observers to detect whales "is imperfect at best" because low light and other poor visibility conditions (such as fog or high-sea states) impair the ability to spot whales and, as Dr. Nowacek goes into further detail, even in ideal conditions it is very difficult to spot whales.[131] This is echoed by Harris et al. stating the "efficacy of a MMO is likely to be low due to the nature of the offshore marine environment in the survey area (frequent high swells and winds affecting surface visibility), putting species who are missed by MMOs and PAM operators at extreme risk, particularly at night or during adverse weather conditions."[132]

118. Passive Acoustic Monitoring (PAM): Harris *et al.* discuss how "the reliance on observers to do visual sightings to supplement the PAM monitoring during the day, as a mandated mitigation measure, necessitates questioning the acceptability of continuing with survey activities at night. If the visual observations are useful (perhaps

[132] Harris Report at Summary of Findings.

SLDS

sighting large animals around 65% of the time) in addition to PAM, then relying on PAM alone at night cannot be an effective mitigation measure. The authors express the opinion that surveys should not occur between sunset and sunrise each day if a real attempt of maximum avoidance of cetaceans is the objective of this mitigation measure."[133]

119. Dr. Nowacek discusses as well the limited benefit of PAM. With PAM, "whales will not be detected even when present if they are quiet or not vocalizing or if background noise is too high." Dr. Nowacek also noted that "studies show that baleen whales cease vocalizing in the presence of even low levels of seismic survey noise."[134]

120. The FBAR's attempts to address this shortcoming in mitigation by equipping MMOs "with infra-red cameras in order to observe mammals at night."[135] However, this is an undeveloped technology for spotting cetaceans. It is not reliable, so much so that it is not typically used by scientists as part of their surveys. Further, there are questions with the scope of view, range/distance, as well as the impact of conditions on the ability to use the technology. In short, it is encouraging to bring new technologies to the table, however it requires more testing and improvement before it could be considered suitably reliable and certainly before it could be factored into the the mitigation of harms to cetaceans.

Lack of baseline noise assessment

121. The FBAR fails to establish an acoustic baseline assessment of the area, and furthermore fails to present a plan to conduct an adequate baseline noise assessment. As part of its recommendations to minimise impacts to marine fauna, the BAR lists:

> Baseline noise measurements can provide useful information (prior to operations) when interpreting underwater noise predictions for the introduction of a new noise source. As such, it is recommended that underwater noise measurements be implemented that would include the deployment of underwater sound monitoring equipment to establish an actual baseline prior

[133] Harris Report at Summary of Findings.
[134] Nowacek Supporting Affidavit at para. 13.4 (incorporating para. 46 of expert declaration by reference).
[135] BAR at 251.

to the commencement of the survey and then operational levels of noise during the survey.[136]

122. The FBAR provides no guidance for the recommended baseline noise measurement, including the duration of monitoring period, or a range or frequency for detection. This lack of detail means it remains impossible to assess if this mitigation step would meet best practice standards such as those put forward by the Marine Mammal Observers Association.

123. The current lack of a baseline assessment means that the ambient background noise considered in the noise modelling falls short of best practices. Best practice acoustical modelling entails collecting site-specific data to calibrate acoustic models that can then be applied to characterize acoustic exposure of marine fauna in a given study area.[137]

Chronic Noise Impacts

124. The seismic survey's airguns consist of 24 active airguns that will blast sound loud enough to penetrate the seabed floor every 6-20 seconds, 24 hours a day, for 70 days.

125. Each acute blast will create direct harms to marine species. In addition, besides the direct harm that the pulse will create, the repetitive blasting will increase ambient noise, even at a distance of 100 kilometres.[138] These two factors expose marine species to chronic noise impacts over a large distance, as the sound travels hundreds and even thousands of kilometres.[139] The BAR fails to take into account the increased stress and behavioural impacts that this chronic noise will cause on marine species in the area of seismic surveying and beyond.

Ground 3: Failure to adequately assess cumulative impacts

126. Below is a map detailing the updated categories of Oil and Gas concessions along the entire coastline of South Africa:

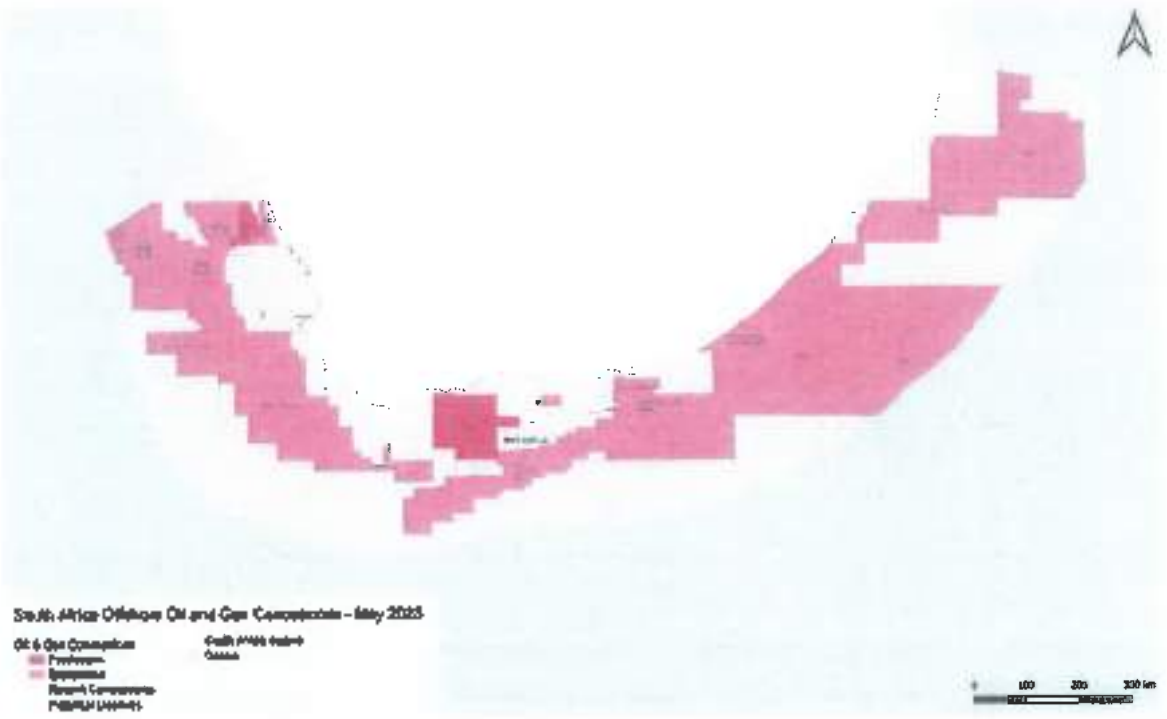
5628

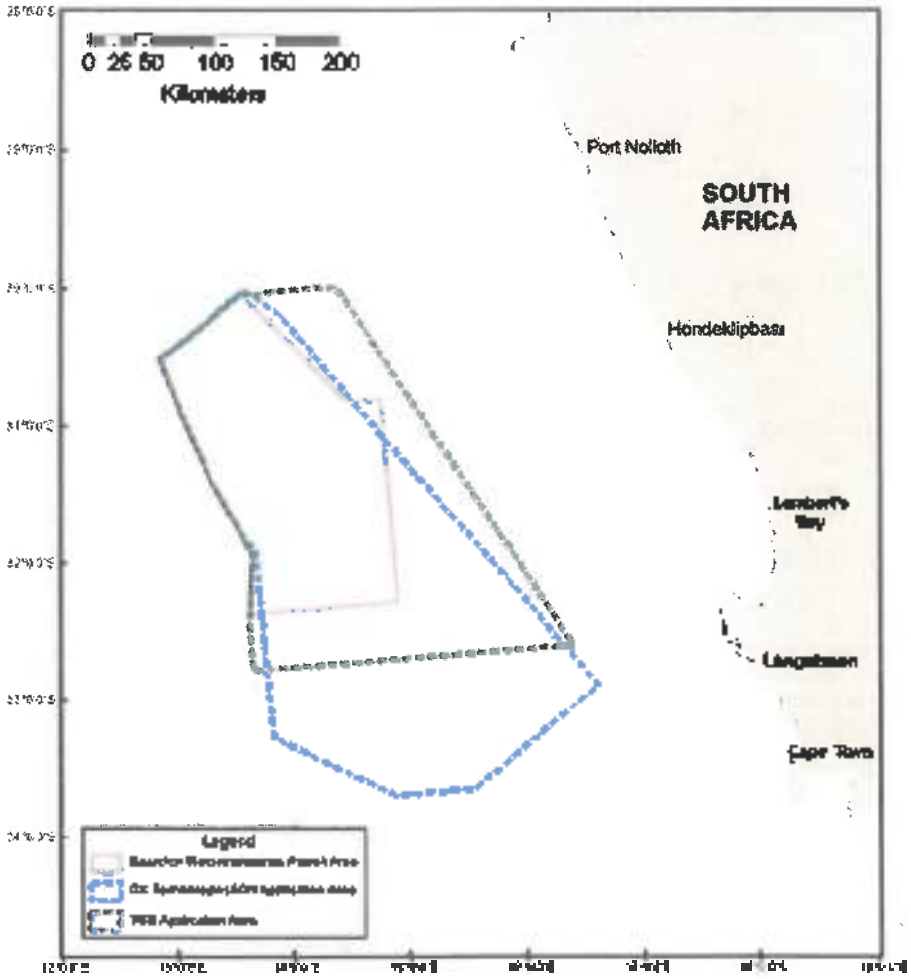


Information received from Petroleum Agency SA, in line with a PAIA Request submitted by the Legal Resources Centre on 12 October 2022

127. In addition to the abovementioned map, it is noted that the BAR acknowledges that should other seismic survey campaigns be undertaken concurrently with TGS's proposed survey programme, cumulative impacts may be likely and there would be a need for alignment in planning of such concurrent operations to reduce cumulative noise impacts to an acceptable significance.[140] The draft BAR notes that there are two current pending applications with PASA (Searcher Geodata and GX Technology Corporation) which both overlap the proposed TGS 3D seismic survey area, as depicted in the diagram below:

[140] Final BAR 1520, para 9.3.5, p234.

5603



Source: TGS draft BAR, p235.

128. The BAR states that despite the difficulty in undertaking a reliable assessment of the potential cumulative environmental impacts of future seismic acquisition in the Deep Water Orange Basin (due to likely variation in the scope, extent and duration of proposed surveys), the cumulative impacts of three potential surveys occurring concurrently needs to be considered. The FBAR thus includes a cumulative assessment which assumes that the three surveys (Searcher, TGS and GX Technologies) occur simultaneously during the summer survey window in 2022/23.

In this event, the draft BAR indicates that:

129. Associated impacts to marine fauna would be of **high intensity** and extend regionally, over the short-term (assuming they take place over the same summer survey window). The impact consequence for cumulative surveys is therefore considered medium.

5428

130. Concurrent activities could also add to the cumulative impact on fisheries. Simultaneous survey operations would result in an increase in the extent and magnitude of the impact on the large pelagic longline sector. The impact duration would remain unchanged. Three seismic surveys of regional extent, undertaken simultaneously, could be expected to result in an impact of medium negative significance on the large pelagic longline sector, both with and without the application of mitigation measures.

131. Curiously, the BAR impact table[141] combines cumulative impacts on marine fauna and fisheries and rates the pre-mitigation environmental significance as 'medium' and the post-mitigation impact as 'low'. This does not reconcile with the preceding paragraphs which indicate with regard to cumulative impacts of three concurrent seismic surveys, an impact of medium negative significance on the large pelagic sector could be expected 'both with and without the application of mitigation measures.

132. The Final BAR states regarding confounding and cumulative effects that the assessments of impacts of seismic sounds provided in the scientific literature usually consider short-term responses at the level of individual animals only, as the understanding of how such short-term effects relate to adverse residual effects at the population level is limited. The report goes on to state that data on behavioural reactions to seismic noise acquired over the short-term could, however, easily be misinterpreted as being less significant than the cumulative effects over the long-term (i.e. what is initially interpreted as an impact not having a detrimental effect and thus being of low significance, may turn out to result in a long-term decline in the population, particularly when combined with other stressors such as temperature, competition for food, and shipping noise). The report notes that confounding effects are, however, difficult to separate from those due to seismic surveys.[142]

133. The report also states that the potential cumulative impacts on individuals and populations as a result of other seismic surveys undertaken either previously, concurrently or subsequently are difficult to assess. The report indicates that a significant adverse residual environmental effect is considered one that affects marine

[141] At p236.
[142] Final BAR 1520, para 9.3.1.4 at p209-210.

biota by causing a decline in abundance or change in distribution of a population(s) over more than one generation within an area. The report makes reference to numerous 2D and 3D seismic surveys having been undertaken off the West Coast over the past 17 years, and relies on reported increases in the southern right whale and humpback whale populations over a time when seismic surveying frequency has increased as '*suggesting that, for these populations at least, there is no evidence of long-term negative change to population size as a direct result of seismic survey activities*'.[143] The assumption made that an increase in whale populations suggests that there is no evidence of long-term negative change to population sizes as a direct result of seismic activities, is questionable. This is an assumption that cannot be inferred from the facts (the increase could be as a result of any number of other external factors).

134. It cannot simply be assumed that the lack of evidence of long-term negative population changes as a direct result of seismic survey activities means that there are no negative impacts (including potentially significant impacts). In their report relating to the TOSACO EIA appeal, Harris *et al* point out that although the humpback whale population is increasing, there is evidence to suggest that cetaceans in South African waters are being affected by changes in their ecosystem and it is not well understood yet what is driving these changes and what the long terms effects could potentially be to populations.[144] Concerns noted in the report include an observed decrease in southern right whale calving success of the South African population and a strong link between foraging success and reproduction.[145] They suggest an investigation into possible decreases and/or spatial or temporal shifts in their prey availability at higher latitudes due to environmental variability. They also highlight a concern of the continued low numbers of unaccompanied adults along the South African coast which

803

could potentially have serious consequences for cow-calf pairs in relation to the country's whale-watching industry in the future.

135. The BAR states that in the 'unlikely' event that multiple surveys would take place at the same time within the same survey area, 'the risk of cumulative noise impact must be considered and is suggested to be managed'. The BAR suggests that mitigation should include maintaining a distance of at least 40 km between survey vessels 'until sufficient objective evidence is obtained that a reduced buffer distance is acceptable'. Where this 40 km buffer distance cannot be maintained, the FBAR suggests that each of the additional activities to those described in the technical noise report should be modelled or otherwise considered in terms of the cumulative noise level and with reference to the criteria described in the report.[146]

136. However, as referred above at paragraphs 109-1113, the US Government prohibits the use of a 40 km buffer as a general mitigation measure and therefore, the mitigation measure must be considered in the site-specific context and include any new information at the time as well as "any potential aggregate effects from existing permitted surveys. This mitigation measure has been proven to be scientifically unsound and ineffective and uses an approach inapposite with the base documents upon which the BAR relies. Therefore, there is no basis for the BAR to conclude that a 40 km buffer will mitigate cumulative impacts of concurrent seismic surveys.

137. Given the lack of certainty regarding cumulative impacts of concurrent 3D seismic survey areas, a risk averse and cautious approach should be applied by not authorising concurrent surveys and suggests that should the decision-maker ought to have refused granting the environmental authorisation.

138. In addition, the FBAR does not consider the cumulative impacts of other proposed offshore oil and gas seismic surveys, exploration and production in other Blocks within South Africa's exclusive economic zone. Having regard to the global Climate

[146] Final BAR, p236.

Emergency[147] and South Africa's international commitment[148] to *'working with others to ensure temperature increases are kept well below 2°C above pre-industrial levels, which could include a further revision of the temperature goal to below 1.5°C in light of emerging science[149]'* by reducing greenhouse gas (GHG) emissions. TGS's proposed 3D seismic survey would, if additional commercially viable resources are identified and developed through to production phase, inevitably add to South Africa's overall GHG emissions (South Africa's energy sector currently contributes an estimated 84% percent to the country's overall GHG emissions).[150] As a reasonably foreseeable future impact that may become more significant, especially in combination with impacts arising from similar offshore oil and gas exploration and production activities, it is submitted that the cumulative impacts[151] of such GHG emissions need to be identified and assessed.

Ground 4: Failure to conduct meaningful consultation with communities and local people (and in particular small-scale fishers), within the public participation process, including the Social Impact Assessment process

139. It is one of the foundational principles of NEMA that the participation of all interested and affected parties must be promoted and the participation of disadvantaged people must be ensured.[152] Section 24(4)(a)(v) of NEMA provides that interested and affected parties must be given a reasonable opportunity to participate in the environmental impact assessment process. Regulation 41(6) provides that the public participation process must be facilitated in a manner that provides all potential interest and affected parties a reasonable opportunity to comment on the proposed

[151] 'Cumulative impact' is defined in the NEMA EIA Regulations as follows: 'in relation to an activity, means the past, current and reasonably foreseeable future impact of an activity, considered together with the impact of activities associated with that activity, that in itself may not be significant, but may become significant when added to the existing and reasonably foreseeable impacts eventuating from similar or diverse activities.

[152] NEMA, section 2(4)(f).

5628

project. Regulation 41(2) of the EIA Regulations requires that the public participation process take into account the relevant guidelines. The 2017 Public Participation Guidelines provide that:

> 137.1. The level of public participation must be informed by the characteristics of the potentially affected parties.[153]
>
> 137.2. The method of communication must be an effective method that will easily reach the intended audiences.[154]
>
> 137.3. The language used must provide all potential interested and affected parties a reasonable opportunity to comment without unnecessary difficulty.[155]

140. The court in *Sustaining the Wild Coast NPC*[156] has upheld this and stated:

> "Meaningful consultation entails providing communities with the necessary information on the proposed activities and affording them an opportunity to make informed representations"[157]

141. Coastal communities and the general public have been overwhelmed with the number of offshore oil and gas related applications running in parallel processes, particularly those which may impact the south-west and west coast of South Africa. In the month of May, I&APs have been called upon to respond to no less than four offshore oil and gas EIA processes, without taking into account legislative public participation processes for the Upstream Petroleum Resources Development Bill and the draft Marine Spatial Plans during a similar period. The EAP in the current application, SLR, has been appointed to conduct three of these parallel EIAs.

142. The table below sets out the various EIA processes, in which it is clear that multiple public meetings and submission dates are running during similar time periods:

143. Many members of the public will be confused by the various applications, with different processes, slightly different due dates, slightly different applicants all being branded the same with the same EAPs conducting similar EIA processes. It is inconceivable that affected coastal communities are able to respond to each of these processes in a meaningful way. This means that fishers must fish for a living, requiring them to be out at sea daily or for extended periods of time. Even if they wish to do so, they do not have the time or resources to attend multiple public meetings, engage with voluminous technical information, provide comments, ascertain whether their comments have been addressed in comments and response reports, and thereafter proceed to draft appeals. The result, even if unintended, is that those who have less resources, who are required to be out at sea to make their livelihoods, and/or who are unable to fully understand the different proposals and processes, are not able participate and engage meaningfully. The chilling effect is that they are significantly prejudiced by the onslaught of applications

144. There are many people, particularly those such as small-scale fishing communities and co-operatives who will be impacted by the project, who do not have access to the

resources and expertise required to access, consider and comment on the records relating to the project, which are voluminous and technical in nature. The current estimate is that around 136 unitary entities could be defined as 'communities' under the proposed community based rights allocation system. In the Western Cape and Northern Cape in particular, these settlements can seldom be described as 'communities' in the sense of small, spatially defined geographic units with a homogenous social structure and shared norms.[158] This is not recognised nor considered in the BAR or SIA in that the reports appear to limit their analysis by failing to consider the intricate social structures and norms within these "communities" thereby considering these communities as homogenous and disregarding their unique characteristics.

145. We attach hereto a letter from Carmelita Mostert, marked **Annex B5**, which was also separately sent to the Appeals Authority, which clearly sets out opposition to the seismic surveys based on the impact on fisheries, and points out their difficulties associated with having to find hardcopy reports and with having to consider how her community's comments have been considered by the EAP.

146. To ensure access to a reasonable, adequate and fair public participation process, TGS and their appointed EAP should have used reasonably distinctive and appropriate alternative methods to inform and educate affected communities and small-scale fishers of the significant adverse impacts that this project could have on them. Running a public participation process during time period could not achieve meaningful and effective consultation.

147. The BAR included a Social Impact Assessment (SIA) that noted[159] that communities feel that there were significant gaps in the available data, and that from a social perspective the non-technical or social risks can potentially cause significant impacts. The report highlighted that potential social impacts identified

[158] Moenieba Isaacs and Mafaniso Hara. 2015. "Backing small-scale fishers: Opportunities and challenges in transforming the fish sector. Institute for Poverty, Land and Agrarian Studies Rural Status Report 2. University of Western Cape, at page 13. [159] Appendix 3.4 to the TGS final BAR, Social Impact Assessment, Equispectives Research and Consulting Services (Sept 2022), at p 101.

FJ28

included:

- Uncertainty;
- Further marginalisation of vulnerable groups;
- Concerns about cumulative impacts;
- Impact on livelihoods;
- Impacts on sense and spirit of place;
- Impacts on social license to operate;
- Stakeholder fatigue and disillusionment;
- Community expectations; and
- Social unrest.

148. These impacts are rated in the final BAR as being of high or medium significance prior to mitigation, and as being medium significance post-mitigation.[160]

149. The report further pointed out that seismic reconnaissance projects are controversial in South Africa, and that while for many stakeholders it is an emotional matter, for others the potential of impacting on their livelihoods is the biggest fear. The report indicates that some stakeholders feel that the exploration for fossil fuels is not in line with sustainable development and the fight against climate change, while other stakeholders feel that it is imperative for the growth and development of the South African economy to engage in these investigations. The expert describes this as a 'complex and wicked problem'.[161]

150. The report went on to state that from a social perspective, it is clear that the communities and the majority of local people are opposed to the project, and that because the project does not happen in a social vacuum, the social environment is much wider than the footprint of the project. The report states further that:

If the social risks and potential damage to cultural and indigenous rights are

---

[160]

[161] Ibid, p8. In a footnote to the TGS final BAR, a 'wicked problem' is indicated as *'a problem that is difficult or impossible to solve because of incomplete, and changing requirements that are often difficult to recognise'.*

JWS

> *considered the impact on the social fabric of already vulnerable communities may be significant. At this stage communities feel that they cannot make informed decisions.*[162] *(emphasis added)*

151. Curiously, while this TGS SIA is almost identical to the SIA submitted in the Searcher draft BAR (ref. 1518), the TGS version omits the following sentence from the above paragraph:

> *From [a] social perspective the project can only be recommended after meaningful consultation, local research, education, and awareness raising has been done in the project affected communities.*[163] *(emphasis added)*

152. An extract from the Searcher SIA is attached marked Annex B4.

153. Instead, the TGS SIA report makes the following recommendation:

> *From a social perspective it is recommended that the project proceed subject to the mitigation measures (i.e. meaningful consultation, local research, education, and awareness raising in the project-affected communities) forming part of the conditions for authorisation and being implemented prior to the commencement of the actual survey.*[164]

154. This recommendation is strikingly different to the recommendation made in the Searcher SIA, which stated as follows:

> *The recommendation is therefore that the project can only proceed once the social mitigation measures have been implemented and the community are sufficiently informed and educated to [be] able to engage in a meaningful manner.*[165] *(emphasis added)*

155. The Appellants submitted in their comments on the draft BAR that recommending that the project proceed subject to meaningful consultation being undertaken – and included as a mitigation measure in the environmental authorisation and implemented prior to the commencement of the 'actual survey' – is highly irregular within the context

---

[162] Ibid, p18.

[165] Searcher 1518 draft BAR SIA, p14.

JL28

of an environmental impact assessment.[166] There is no legal basis for meaningful consultation to be undertaken after an environmental authorisation is granted, and including such a recommendation as a condition of authorisation undermines the regulatory scheme for prior impact assessment that is subjected to public consultation.

156. Notwithstanding the above mentioned submissions, the environmental authorisation ("EA") approves the BAR and EMPr, and indicates that it is mandatory for the holder to implement all the recommendations and management measures stipulated in the EMPr throughout all phases of the proposed activities.[167] The EA also stipulates as a specific condition that a community engagement protocol that is based on the San Code of Research Ethics be developed, in consultation with the affected communities and must include a community strategy and grievance mechanism.[168] The EMPr in turn includes as mitigation measures various recommendations under the heading 'Socio-Economic Considerations', all of which are indicated as to be implemented 'Prior to Operation and ongoing'.

157. The Appellants submit that notwithstanding the public participation processes conducted during the BAR and the SIA processes (which the appellants submitted in paragraphs 115- 121 above, were not adequate or meaningful), it is clear from the SIA that communities and the majority of local people are opposed to the project and that seismic survey companies do not have a 'social license to operate'. The SIA indicates that *'If TGS…wants to proceed with the project, they will need to engage in meaningful conversation with the communities and try to restore relationships. From a community and social risk perspective this is not negotiable'.*[169] The inclusion of mitigation measures in the EMPr (and by reference the EA) fails to adequately take into account the needs and values of the communities (and small scale fishers) who are opposed to the seismic survey.[170] Their voices in opposition to the seismic survey remain unheard in the final BAR

[166] Para 120 at page 60 of Green Connection and Natural Justice DBAR comment submission.

5 CDS

and EA. Furthermore, it is submitted that the mitigation measure that TGS should (prior to the operation and on an ongoing basis) *'consult with the traditional leadership of the affected communities to establish what their understanding of meaningful consultation is and how communities should be consulted in the future'*[171] cannot be a substitute for meaningful consultation with communities and local people during the EIA process. It is submitted further that such an approach violates the principles of fair administrative decision-making and the right of interested and affected communities to be meaningfully consulted prior to a decision on authorisation being made, and is inconsistent with section 2(4)(f) of NEMA, which stipulates that the participation of all interested and affected parties in environmental governance must be promoted, and all people must have the opportunity to develop the understanding, skills and capacity necessary for achieving equitable and effective participation, and participation by vulnerable and disadvantaged persons must be ensured.

158. The Appellants also note that the SIA states further that the seismic survey industry should reassess their position and social license to operate as an industry in the South African context and should conduct a strategic environmental assessment of the impact of the industry.[172] Notwithstanding this, the report makes a one-sided assumption that the discovery of commercially exploitable fossil oil or gas resources would be beneficial to the economic development of South Africa: *'Potential future benefits and the economic development of the country should the surveys find any significant resources are not disputed'*.[173] The Green Connection and Natural Justice submit that the SIA should have reflected the many negative socio-economic impacts that could or are likely to manifest should commercially exploitable reserves be found and developed through to production and use (including but not limited to the socio-economic costs of climate change[174]).

[174] In 2021 an international team of scientists published their findings that economic damage from climate change could be six times higher by the end of this century than previously estimated. See: https://www.ucl.ac.uk/news/2021/sep/economic-cost-climate-change-could-be-six-times-higher-previously-thought

1703

159. In light of the above, the Appellants submit that the public participation process, including the SIA conducted, did not constitute meaningful consultation with communities and local people (and in particular small-scale fishers), and that the mitigation measures requiring further consultation after the EIA has been conducted and a decision on authorisation made (but prior to the operation and ongoing thereafter) does not cure this flaw in the EIA process. As a consequence, it is submitted that the EA should be overturned on appeal.

Ground 5. The FBAR does not contain a proper and objective assessment of the negative impacts of the project on people's human rights

160. Small-scale or subsistence fishers in coastal communities heavily rely on local fish populations for their livelihood and cultural practices. If seismic surveys lead to a reduction in fish stocks, it can have negative consequences for these fishers. They may experience reduced catch rates, economic losses, and disruptions to their traditional fishing practices. Furthermore, the cultural and heritage aspects tied to fishing may be undermined if fish populations decline significantly, as it can impact the intergenerational transmission of traditional knowledge and practices.
